If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interface value
$value = $deprovision_info->interface();

#Set interface value
$deprovision_info->interface($interface);
```

network( )

Use this method to set or retrieve the network address.

Parameter

Valid value is a string representing the address and netmask of the network in CIDR format (example: 10.0.0.0/8).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $deprovision_info->network();

#Set attribute value
$deprovision_info->network("10.0.0.0/8");
```

network_view( )

Use this method to set or retrieve the network view name.

Parameter

Valid value is a string representing network view name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $deprovision_info->network_view();

#Set attribute value
$deprovision_info->network_view($view);
```

NAME

Infoblox::Grid::Discovery::Port - the discovery port structure.

DESCRIPTION

The object provides information about the discovery port.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Discovery::Port->new(
    'comment' => $string,            # Optional
    'port'    => $uint,              # Required
    'type'    => 'TCP' | 'UDP',      # Required
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

comment( )

Use this method to set or retrieve the comment.

Parameter

The comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->comment();
# Modify attribute value
$object->comment('comment');
```

port( )

Use this method to set or retrieve the port number.

Parameter

The port number.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->port();
# Modify attribute value
$object->port(56);
```

type( )

Use this method to set or retrieve the port type.

Parameter

Valid value is 'TCP' or 'UDP'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->type();
# Modify attribute value
$object->type('UDP');
```

NAME

Infoblox::Grid::Discovery::Port::Config::AdminStatus - admin status of port configuration.

DESCRIPTION

The object provides information about the admin status of port configuration.

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to retrieve the attribute values of the object.

status( )

Use this method to retrieve the configured admin status. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value that can be 'UP' or 'DOWN'.

Example

```
# Get attribute value
my $value = $object->status();
```

task_details( )

Use this method to retrieve task details of the port control. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::Port::Control::TaskDetails object.

Example

```
# Get attribute value
my $value = $object->task_details();
```

DESCRIPTION

The object provides information about the port configuration description.

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to retrieve the attribute values of the object.

description( )

Use this method to retrieve the configured description. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->description();
```

task_details( )

Use this method to retrieve task details of the port control. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::Port::Control::TaskDetails object.

Example

```
# Get attribute value
my $value = $object->task_details();
```

Infoblox::Grid::Discovery::Port::Config::VlanInfo - VLAN information of port configuration.

DESCRIPTION

The object provides information about the port configuration VLAN.

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to retrieve the attribute values of the object.

data_vlan_info( )

Use this method to retrieve information about data VLAN. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::VLANInfo object.

Example

```
# Get attribute value
my $value = $object->data_vlan_info();
```

task_details( )

Use this method to retrieve task details of the port control. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::Port::Control::TaskDetails object.

Example

```
# Get attribute value
my $value = $object->task_details();
```

voice_vlan_info( )

Use this method to retrieve information about voice VLAN. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::VLANInfo object.

Example

```
# Get attribute value
my $value = $object->voice_vlan_info();
```

Infoblox::Grid::Discovery::Port::Control::Info - port control information.

DESCRIPTION

The object provides information about port control.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Discovery::Port::Control::Info->new(
    'device'            => $device,          # optional
    'interface'         => $interface,       # required
    'data_vlan_info'    => $vlan_info,       # optional
    'voice_vlan_info'   => $vlan_info,       # optional
    'admin_status'      => 'UP' | 'DOWN',    # optional
    'description'       => $string,          # optional
    'parent'            => $parent,          # optional
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

admin_status( )

Use this method to set or retrieve the administrative state of the interface.

Parameter

Valid value is 'UP' or 'DOWN'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->admin_status();
# Modify attribute value
$object->admin_status('UP');
```

data_vlan_info( )

Use this method to set or retrieve information about data VLAN of the interface.

Parameter

Valid value is an Infoblox::Grid::Discovery::VLANInfo object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->data_vlan_info();
# Modify attribute value
$object->data_vlan_info($vlan_info);
```

description( )

Use this method to set or retrieve the description of the interface.

Parameter

The description in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->description();
# Modify attribute value
$object->description('example');
```

device( )

Use this method to set or retrieve the device.

Parameter

Valid value is an Infoblox::Grid::Discovery::Device object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->device();
# Modify attribute value
$object->device($device);
```

interface( )

Use this method to set or retrieve the interface.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->interface();
# Modify attribute value
$object  interface $interface
```

```
->          (          );
```

parent( )

Use this method to set or retrieve the parent to which port is configured.

Parameter

Valid value is Infoblox::Grid::Discovery::DeviceInterface, Infoblox::DNS::Host, Infoblox::DHCP::FixedAddr, Infoblox::DHCP::IPv6FixedAddr or Infoblox::Grid::Member object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->parent();
# Modify attribute value
$object->parent($parent);
```

voice_vlan_info( )

Use this method to set or retrieve information about voice VLAN of the interface.

Parameter

Valid value is an Infoblox::Grid::Discovery::VLANInfo object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->voice_vlan_info();
# Modify attribute value
$object->voice_vlan_info($vlan_info);
```

Infoblox::Grid::Discovery::Port::Control::TaskDetails - port control task details.

DESCRIPTION

The object provides information about port control task details.

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to retrieve the attribute values of the object.

id( )

Use this method to retrieve the task ID. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->id();
```

is_synchronized( )

Use this method to retrieve the flag indicates if the task completed and matched with current discovered value. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->is_synchronized();
```

status( )

Use this method to retrieve the task status. This attribute is read-only.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->status();
```

    'snmp_credentials'               => [$snmp_1, ...],       # Optional
    'cli_credentials'                => [$cli1, ...],         # Optional
    'discovery_blackout_setting'     => $blackout,            # Optional
    'port_control_blackout_setting' => $blackout,             # Optional
    'ports'                          => [$port1, ...],        # Optional
    'ignore_conflict_duration'       => $uint,                # Optional
    'same_port_control_discovery_blackout' => 'true' | 'false' # Optional
    'unmanaged_ips_limit'            => $uint,                  # Optional
    'unmanaged_ips_timeout'          => $uint,                  # Optional
    'vrf_mapping_rules'              => [$vrf_rule_1, ...],     # Optional
    'vrf_mapping_policy'             => 'NONE' | 'RULE_BASED' | 'RULE_AND_INTERNAL_BASED', # Optional
);
```

SESSION METHODS

This section describes all the methods in Infoblox::Session that you can apply to a object.

Infoblox::Session->get( )

Use this method to retrieve the existing object from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my $object = $session->get('object' => 'Infoblox::Grid::Discovery::Properties');
```

Infoblox::Session->modify( )

Use this method to modify object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
my $port = Infoblox::Grid::Discovery::Port->new(
    'port' => 40,
    'type' => 'UDP',
);

# Use method to modify ports
$object->ports([$port]);
# Submit modification
my $response = $session->modify( $object );
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

advanced_polling_settings( )

Use this method to set or retrieve discovery advanced poll settings.

Parameter

Valid value is an Infoblox::Grid::Discovery::AdvancedPollSettings object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->advanced_polling_settings();
# Modify attribute value
$object->advanced_polling_settings($adv);
```

auto_conversion_settings( )

Use this method to set or retrieve a list of automatic conversion settings.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::AutoConversionSetting objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->auto_conversion_settings();
# Modify attribute value
$object->auto_conversion_settings([$auto_conversion_settings1, $auto_conversion_settings2]);
```

basic_polling_settings( )

Use this method to set or retrieve discovery basic poll settings.

Parameter

Valid value is an Infoblox::Grid::Discovery::BasicPollSettings object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->basic_polling_settings();
# Modify attribute value
$object->basic_polling_settings($basic);
```

enable_auto_conversion( )

Use this method to set or retrieve the flag that enables automatic conversion of discovered data.

Parameter

Specify 'true' to enable automatic conversion of discovery data or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->enable_auto_conversion();
# Modify attribute value
$object->enable_auto_conversion('true');
```

enable_auto_updates( )

Use this method to set or retrieve the flag that enables updating discovered data for managed objects.

Parameter

Specify 'true' to enable updating discovered data for managed objects or 'false' to disable it. The default value is 'true'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->enable_auto_updates();
# Modify attribute value
$object->enable_auto_updates('true');
```

cli_credentials( )

Use this method to set or retrieve the discovery CLI credentials.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::CLICredential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->cli_credentials();
# Modify attribute value
$object->cli_credentials([$cli1, $cli2]);
```

discovery_blackout_setting( )

Use this method to set or retrieve the discovery blackout setting.

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->discovery_blackout_setting();
# Modify attribute value
$object->discovery_blackout_setting($blackout);
```

ignore_conflict_duration( )

Use this method to set or retrieve the ignore discovery conflict duration.

Parameter

The ignore discovery conflict duration in seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->ignore_conflict_duration();
# Modify attribute value
$object->ignore_conflict_duration(3600);
```

ports( )

Use this method to set or retrieve ports to scan.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::Port objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->ports();
# Modify attribute value
$object->ports([$port1, $port2]);
```

port_control_blackout_setting( )

Use this method to set or retrieve the port control blackout setting.

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->port_control_blackout_setting();
# Modify attribute value
$object->port_control_blackout_setting($blackout);
```

same_port_control_discovery_blackout( )

Use this method to set or retrieve the flag that enables using the same discovery blackout for port control blackout.

Parameter

Specify 'true' to use same discovery blackout for port control blackout or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->same_port_control_discovery_blackout();
# Modify attribute value
$object->same_port_control_discovery_blackout('true');
```

snmp3_credentials( )

Use this method to set or retrieve a list of discovery SNMPv3 credentials.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::SNMP3Credential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->snmp3_credentials();
# Modify attribute value
$object->snmp3_credentials([$snmp3_1, $snmp3_2]);
```

snmp_credentials( )

Use this method to set or retrieve a list of discovery SNMP v1 and v2 credentials>.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::SNMPCredential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->snmp_credentials();
# Modify attribute value
$object->snmp_credentials([$snmp1, $snmp2]);
```

test_credential( )

Use this method to test credentials.

Note that this method does not perform automatic polling for the operational status. It returns a snapshot of the status at the time when you call the method, which may not be the final status. To get the latest status, the client script needs to provide polling logic for this method until the operation status is 'INPROGRESS' by calling the method with start parameter assigned to the end field in the previous call result. For more details, see the example below.

Parameter

```
id              - Optional. The test credential ID.
```

The following members are supported when id is defined:

```
start           - Optional. The start position of the text.
```

The following members are supported when id is not defined:

```
 view             - Optional. The network view name. The default value is the system-defined default
network view.

 type             - Optional if one of the following is defined: cli_credentials, snmp_credential, or
snmp3_credential. Otherwise, this member is required. The valid value is 'CLI', 'SNMP' or 'SNMP3'.

 device           - Required if address is not defined. The Infoblox::Grid::Discovery::Device object.

 member           - Optional. The discovery member name.

 address          - Required if device is not defined. The IP address of the device.

 cli_credentials  - Optional. At least one of the following must be defined: cli_credentials,
snmp_credential, or snmp3_credential. The array reference that contains
Infoblox::Grid::Discovery::CLICredential objects.

 snmp_credential  - Optional. At least one of the following must be defined: cli_credentials,
snmp_credential, or snmp3_credential. The Infoblox::Grid::Discovery::SNMPCredential object.

 snmp3_credential - Optional. At least one of the following must be defined: cli_credentials,
snmp_credential, or snmp3_credential. The Infoblox::Grid::Discovery::SNMP3Credential object.
```

Returns

The method returns an Infoblox::Grid::Discovery::TestCredential object when the operation succeeds, and returns false when the operation fails.

Example

```
# Get a test credential ID
my $result = $object->test_credential(
   'address'         => '10.0.0.1',
   'snmp_credential' => $snmp,
);

# Get detailed information by id
if (ref($result) eq 'Infoblox::Grid::Discovery::TestCredential') {
    $result = $object->test_credential('id' => $result->id());
}

# check for the 'COMPLETE' or 'FAILED' status of test credential
while (ref($result) eq 'Infoblox::Grid::Discovery::TestCredential' &&
       $result->status() eq 'INPROGRESS') {
    $result = $grid->test_credential('id' => $result->id(), 'start' => $result->end());
}
```

unmanaged_ips_limit( )

Use this method to set or retrieve the limit value for discovered unmanaged IP addresses. This value determines how often users are notified when new unmanaged IP addresses are discovered in a particular network.

Parameter

The valid value is an unsigned integer. The minimun value is 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->unmanaged_ips_limit();
# Modify attribute value
$object->unmanaged_ips_limit(30);
```

unmanaged_ips_timeout( )

Use this method to set or retrieve the timeout value (in seconds) between notifications about new unmanaged IP addresses in a particular network.

Parameter

The valid value is an unsigned integer. The minimum value is 60 (one minute), and the maximum value is the number of seconds from the time you set it until January 2038.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->unmanaged_ips_timeout();
# Modify attribute value
$object->unmanaged_ips_timeout(300);
```

vrf_mapping_rules( )

Use this method to set or retrieve a list of VRF mapping rules.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::VRFMappingRule objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->vrf_mapping_rules();
# Modify attribute value
$object->vrf_mapping_rules([$vrf_mapping_rule1, $vrf_mapping_rule2]);
```

vrf_mapping_policy( )

Use this method to set or retrieve the VRF mapping policy.

Parameter

The policy type used to define the behavior of the VRF mapping. Valid value is one of the following policy types: 'NONE', 'RULE_BASED', 'RULE_AND_INTERNAL_BASED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->vrf_mapping_policy();
# Modify attribute value
$object->vrf_mapping_policy('RULE_AND_INTERNAL_BASED');
```

NAME

Infoblox::Grid::Discovery::Properties::BlackoutSetting

DESCRIPTION

The object provides information about the discovery or port control blackout settings.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Discovery::Properties::BlackoutSetting->new(
    'enable_blackout'   => 'true' | 'false',      # optional
    'blackout_duration' => $uint,                 # optional
    'blackout_schedule' => $schedule,             # optional
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

blackout_duration( )

Use this method to set or retrieve the blackout duration.

Parameter

The blackout duration in minutes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->blackout_duration();
# Modify attribute value
$object->blackout_duration(10);
```

blackout_schedule( )

Use this method to set or retrieve the blackout schedule.

Parameter

Valid value is an Infoblox::Grid::ScheduleSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->blackout_schedule();
# Modify attribute value
$object->blackout_schedule($schedule);
```

enable_blackout( )

Use this method to enable or disable the Discovery or port control blackout.

Parameter

Specify 'true' to enable the discovery or port control blackout or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->enable_blackout();
# Modify attribute value
$object->enable_blackout('true');
```

NAME

Infoblox::Grid::Discovery::SeedRouter - The seed router structure.

DESCRIPTION

The object provides information about the seed router.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Discovery::SeedRouter->new(
    'address'      => $ipaddr,       # Required
    'network_view' => $string,       # Optional
    'comment'      => $string,       # Optional
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

address( )

Use this method to set or retrieve the IP address of the seed router.

Parameter

The IP address in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->address();
# Modify attribute value
$object->address('10.0.0.1');
```

network_view( )

Use this method to set or retrieve the network view associated with the seed router.

Parameter

The name of the network view

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->network_view();
# Modify attribute value
$object->network_view('papi_network_view');
```

comment( )

Use this method to set or retrieve the description of the seed router.

Parameter

The description of the seed router in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->comment();
# Modify attribute value
$object->comment('comment');
```

Infoblox::Grid::Discovery::SNMP3Credential - SNMPv3 credential.

DESCRIPTION

The object provides information about SNMPv3 credential.

CONSTRUCTOR

```
 my $object = Infoblox::Grid::Discovery::SNMP3Credential->new(
    'authentication_password' => $string,                          # Required if authentication_protocol is
MD5 or SHA
    'authentication_protocol' => 'MD5' | 'NONE' | 'SHA',           # Requred
    'comment'                 => $string,                          # Optional
    'privacy_password'        => $string,                          # Required if privacy_protocol is 'AES',
'DES' or '3DES'
    'privacy_protocol'        => 'AES' | 'DES' | '3DES' | 'NONE', # Required
    'user'                    => $string,                          # Required
 );
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

authentication_password( )

Use this method to set the authentication password if the authentication protocol is MD5 or SHA. This is a write-only attribute.

Parameter

The authentication password in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
 # Modify attribute value
 $object->authentication_password('infoblox');
```

authentication_protocol( )

Use this method to set or retrieve the authentication protocol.

Parameter

Valid value is 'MD5', 'NONE' or 'SHA'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->authentication_protocol();
# Modify attribute value
$object->authentication_protocol('MD5');
```

comment( )

Use this method to set or retrieve the comment on SNMPv3 user.

Parameter

The comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->comment();
# Modify attribute value
$object->comment('SNMPv3');
```

privacy_password( )

Use this method to set the privacy password if the privacy protocol is 'AES', 'DES' or '3DES'. This is a write-only attribute.

Parameter

The privacy password in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
# Modify attribute value
$object->privacy_password('infoblox');
```

privacy_protocol( )

Use this method to set or retrieve the privacy protocol.

Parameter

Valid value is 'AES', 'DES', '3DES' or 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->privacy_protocol();
# Modify attribute value
$object->privacy_protocol('3DES');
```

user( )

Use this method to set or retrieve the SNMPv3 user name.

Parameter

Tthe SNMPv3 user name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->user();
# Modify attribute value
$object->user('admin');
```

DESCRIPTION

The object provides information about SNMPv1 and SNMPv2 credential.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Discovery::SNMPCredential->new(
    'comment'          => $string,    # Optional
    'community_string' => $string,    # Required
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

comment( )

Use this method to set or retrieve the comment on SNMPv1 and SNMPv2 user.

Parameter

The comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->comment();
# Modify attribute value
$object->comment('comment');
```

community_string( )

Use this method to set or retrieve the public community string.

Parameter

The public community string.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->community_string();
# Modify attribute value
$object->community_string('string');
```

NAME

Infoblox::Grid::Discovery::Status - the discovery status of discovered data.

DESCRIPTION

The object provides information about the discovery status of discovered data.

SESSION METHOD

This section describes all the methods in Infoblox::Session that you can apply to the object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific object:

 address - Optional. The IP address of the device.
 name    - Optional. The device name.
 network_view - Optional. The network view name.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::Discovery::Status',
    'address' => '10.0.0.1',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a object:

 address - Optional. The IP address of the device (regular expression).
 name    - Optional. The device name (regular expression).
 network_view - Optional. The network view name.
```

Example

```
# search for all objects
my @retrieved_objs = $session->search(
    'object' => 'Infoblox::Grid::Discovery::Status',
    'address' => '10.0.0.1',
);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

address( )

Use this method to retrieve the IP address of the device. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->address();
```

cli_collection_enabled( )

Use this method to retrieve the flag that indicates if CLI collection is enabled. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'true' or 'false'.

Example

```
#Get attribute value
my $value = $status->cli_collection_enabled();
```

existence_info( )

Use this method to retrieve information about the device existence status. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::StatusInfo object.

Example

```
# Get attribute value
my $value = $object->existence_info();
```

fingerprint_enabled( )

Use this method to retrieve the flag that indicates if DHCP fingerprinting is enabled. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'true' or 'false'.

Example

```
# Get attribute value
my $value = $object->fingerprint_enabled();
```

fingerprint_info( )

Use this method to retrieve information about the device fingerptint status. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::StatusInfo object.

Example

```
# Get attribute value
my $value = $object->fingerprint_info();
```

first_seen( )

Use this method to retrieve the timestamp when the device was first discovered. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->first_seen();
```

last_action( )

Use this method to retrieve the timestamp of the last detected interface property change. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->last_action();
```

last_seen( )

Use this method to retrieve the timestamp when the device was last discovered. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->last_seen();
```

last_timestamp( )

Use this method to retrieve the timestamp of the last action executed for the device. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->last_timestamp();
```

name( )

Use this method to retrieve the device name. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->name();
```

network_view( )

Use this method to retrieve the network view name. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->network_view();
```

reachable_info( )

Use this method to retrieve information about the device reachable status. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::StatusInfo object.

Example

```
# Get attribute value
my $value = $object->reachable_info();
```

snmp_collection_enabled( )

Use this method to retrieve the flag that indicates whether SNMP collection is enabled for the device. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'true' or 'false'.

Example

```
# Get attribute value
my $value = $object->snmp_collection_enabled();
```

snmp_collection_info( )

Use this method to retrieve information about the device SNMP collection status. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::StatusInfo object.

Example

```
# Get attribute value
my $value = $object->snmp_collection_info();
```

snmp_credential_info( )

Use this method to retrieve information about the device SNMP credential status. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be an Infoblox::Grid::Discovery::StatusInfo object.

Example

```
# Get attribute value
my $value = $object->snmp_credential_info();
```

status( )

Use this method to retrieve the status of the device. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'OK', 'ERROR' or 'NON_REACHABLE'.

Example

```
# Get attribute value
my $value = $object->status();
```

type( )

Use this method to retrieve the device type. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->type();
```

Infoblox::Grid::Discovery::StatusInfo - the discovery status information.

DESCRIPTION

The object provides information about the discovery status.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Discovery::StatusInfo->new(
    'message'   => $string,                                  # Required
    'status'    => 'OK' | 'ERROR' | 'NON_REACHABLE',         # Required
    'timestamp' => $epoch,                                   # Required
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

message( )

Use this method to set or retrieve the detailed message.

Parameter

The detailed message in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->message();
# Modify attribute value
$object->message('text');
```

status( )

Use this method to set or retrieve the status of the device.

Parameter

Valid value is 'OK', 'ERROR' or 'NON_REACHABLE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->status();
# Modify attribute value
$object->status('OK');
```

timestamp( )

Use this method to set or retrieve the timestamp when status was generated.

Parameter

The date and time in the ISO 8601 extended format (e.g. 2008-10-21T10:56:33Z or 2008-10-21T10:56:33.001Z).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->timestamp();
# Modify attribute value
$object->timestamp('2008-10-21T10:56:33Z');
```

Infoblox::Grid::Discovery::TestCredential

DESCRIPTION

The object provides information about results of the test credential.

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

end( )

Use this method to retrieve the end position of the returned text. This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->end();
```

id( )

Use this method to retrieve the test credential ID. This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->id();
```

status( )

Use this method to retrieve the test credential status. This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETED', 'FAILED' or 'INPROGRESS'.

Example

```
# Get attribute value
my $value = $object->status();
```

text( )

Use this method to retrieve the portion of the text from start (inclusive) to end (exclusive). This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->text();
```

id( )

Use this method to set or retrieve the VLAN ID.

Parameter

The VLAN ID in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->id();
# Modify attribute value
$object->id('23');
```

name( )

Use this method to set or retrieve the VLAN name.

Parameter

The VLAN name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->name();
# Modify attribute value
$object->name('vlan');
```

NAME

Infoblox::Grid::Discovery::VRFMappingRule - VRF mapping rule.

DESCRIPTION

The object provides mapping of regular expressions that represent the VRF name and network view.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Discovery::VRFMappingRule->new(
    'network_view'      => $string,     # Required
    'criteria'          => $string,     # Required
    'comment'           => $string,     # Optional
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

network_view( )

Use this method to set or retrieve the name of the network view associated with the VRF mapping rule.

Parameter

The name of the network view associated with the VRF mapping rule.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->network_view();
# Modify attribute value
$object->network_view('default');
```

criteria( )

Use this method to set or retrieve the criteria of the VRF mapping rule.

Parameter

Extended POSIX regular expression matching the VRF name. The regular expression string should contain the leading caret anchor ^ and the trailing dollar anchor $ symbols.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->criteria();
# Modify attribute value
$object->criteria('.*+Red\d');
```

comment( )

Use this method to set or retrieve the comment for the VRF mapping rule.

Parameter

The comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->comment();
# Modify attribute value
$object->comment('comment');
```

NAME

Infoblox::Grid::DistributionSchedule - Information about the Grid's distribution schedule.

DESCRIPTION

The Distribution Schedule object is used to set and view the distribution schedule of an Infoblox Grid.

CONSTRUCTOR

The Infoblox::Grid::DistributionSchedule object is automatically generated. It does not require manual construction.

SESSION METHODS

This section describes all the methods in an Infoblox::Session that can be applied to a Distribution Schedule object.

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my $schedule = $session->get(object => "Infoblox::Grid::DistributionSchedule");
```

Infoblox::Session->modify( )

Use this method to modify objects in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Submit modification
my $response = $session->modify( $schedule );
```

METHODS

This section describes all the methods that can be used to set or retrieve the attribute values of a Distribution Schedule object.

active( )

Use this method to set or retrieve the "active" flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the active flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get active
my $active = $schedule->active();
#Modify active
$schedule->active("true");
```

groups( )

Use this method to set or retrieve the list of groups affected by this distribution schedule.

Parameter

Array reference that contains each Infoblox::Grid::Upgradegroup object.

Note that the members of this list must have their distribution_time parameter set in order for the modification to succeed. This means that it is possible to retrieve a distribution schedule but not be allowed to modify it without setting the distribution_time values for the groups.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get the group list
my $grouplist = $schedule->groups();
#Modify it
$grid->groups([$ug1, $ug2, $ug3 ]);
```

start_time( )

Use this method to set or retrieve the start time of the distribution.

Parameter

The start time of the distribution in ISO 8601 extended format (e.g. 2008-10-21T10:56:00Z or 2008-10-21T10:56:00.001Z).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get start_time
my $start_time = $schedule->start_time();
#Modify start_time
$schedule->start_time("2020-12-21T11:22:33Z");
```

time_zone( )

Use this method to set or retrieve the time zone of the distribution schedule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The UTC string that represents the time zone. For example "(UTC - 6:00) Central Time (US and Canada)". Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get time_zone
my $time_zone = $schedule->time_zone();
#Modify time_zone
$schedule->time_zone("(UTC - 6:00) Central Time (US and Canada)");
```

NAME

Infoblox::Grid::DNS - DNS objects management and configuration

DESCRIPTION

This class supports DNS service management and configuration such as time-to-live (TTL) settings, zone transfers, queries, root name servers, dynamic updates, sort lists, Transaction Signatures (TSIG) for DNS and others, all at the grid level.

The service configurations of a grid are inherited by all members, zones, and networks unless you specifically override them for selected members, zones, and networks. For this reason, it is recommended that you configure services at the grid level before configuring member, zone and network services.

CONSTRUCTOR

The Infoblox::Grid::DNS object is automatically generated upon the successful installation of the Infoblox appliance. It does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a grid DNS object.

Infoblox::Session->get( )

Use this method to retrieve the matching grid DNS object from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific grid DNS object:

 name - Required. A grid name in string format.
```

Example

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS",
    name   => "Infoblox"
    );
```

Infoblox::Session->modify( )

Use this method to modify a grid DNS object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to take effect. See Infoblox::Session->restart() method.

Example

```
#Use this method to modify the grid  DNS service.
$grid_dns->allow_recursive_query("true");
#Submit modification
my $response = $session->modify( $grid_dns );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a grid DNS object.

allow_bulkhost_ddns( )

Use this method to set or retrieve the allow_bulkhost_ddns flag of a grid DNS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the allow_bulkhost_ddns flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get  the allow_bulkhost_ddns flag
my $allow_bulkhost_ddns = $grid_dns->allow_bulkhost_ddns();
#Modify allow bulkhost ddns flag
$grid_dns->allow_bulkhost_ddns("true");
```

allow_gss_tsig_zone_updates( )

Use this method to set or retrieve the allow_gss_tsig_zone_updates flag of a grid.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get  the allow_gss_tsig_zone_updates flag
my $allow_gss_tsig_zone_updates = $grid_dns->allow_gss_tsig_zone_updates();
#Modify allow_gss_tsig_zone_updates flag
$grid_dns->allow_gss_tsig_zone_updates("true");
```

allow_query( )

Use this method to set or retrieve the list of allowed/denied queries for a Grid DNS object. The list specifies IP addresses and/or networks from which queries are allowed or denied. The appliance can also use TSIG keys to authenticate the queries.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses, networks and/or Infoblox::DNS::TSIGKey objects. To deny queries, add "!" as a prefix to addresses and networks. Specify "any" to allow queries from any address. By default, queries are allowed from any address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get allow query list
my $allow_query_list = $grid_dns->allow_query();
#Modify allow query list
$grid_dns->allow_query(["any"]);

#Specifying TSIG keys
my $tsig_key1 = $session->gen_tsig_key();
my $query_key = Infoblox::DNS::TSIGKey->new(
    name => "query_key1",
    key  => $tsig_key1
);
#Modify allow query list
```

```
 $grid_dns->allow_query(["10.0.0.10" , "20.0.0.0/24" ,"2001::123a","2003::222/64", "!"."30.0.0.30",
$query_key, "!"."40.10.0.0/24","!"."2004::125b","!"."2006::34bc"]);
 #Use Infoblox::Grid::NamedACL
 $grid_dns->allow_query($nacl);
```

allow_recursive_query( )

Use this method to set or retrieve the allow_recursive_query flag of a grid DNS object. If enabled and the Infoblox appliance receives a query for DNS data, it sends a recursive query to the configured internal root servers. If there are no internal root servers configured, the appliance then sends a recursive query to the Internet root servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the allow_recursive_query flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
 #Get allow recursive query flag
 my $allow_recursive_query = $grid_dns->allow_recursive_query();
 #Modify allow recursive query flag
 $grid_dns->allow_recursive_query("true");
```

allow_transfer( )

Use this method to set or retrieve the list of allowed/denied zone transfers for a Grid DNS object. The list specifies IP addresses and/or networks from which zone transfers are allowed or denied. It is also possible to specify the TSIG keys of clients that are allowed to perform zone transfers. TSIG keys are used to authenticate zone transfer requests and replies. The same key name and key value must be on the primary and secondary name servers for TSIG-authenticated zone transfers to occur.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses, networks, and/or Infoblox::DNS::TSIGKey objects. To deny zone transfer, add "!" as a prefix to IP addresses and/or networks. Specify "any" to allow transfers from any IP address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
 #Get allow transfer list
 my $allow_transfer_list = $grid_dns->allow_transfer();
 #Modify allow transfer list
 $grid_dns->allow_transfer(["any"]);

 #Specifying TSIG keys
 my $tsig_key1 = $session->gen_tsig_key();
 my $key1 = Infoblox::DNS::TSIGKey->new(
     name => "key1",
     key  => $tsig_key1
 );
 my $key2 = Infoblox::DNS::TSIGKey->new(
     name => "tsig_xfer",
     key  => ":2xCOMPAT"
     );
 #Modify allow transfer list
 $grid_dns->allow_transfer(["10.0.0.10", "20.0.0.0/24","2004::325f","2007::876c/64","!"."30.0.0.30",
$key1, $key2, "!"."40.10.0.0/24"]);
 #Use Infoblox::Grid::NamedACL
 $grid_dns->allow_transfer($nacl);
```

allow_update( )

Use this method to set or retrieve the list of allowed/denied dynamic updates for a grid DNS object. The list specifies from which IP addresses, networks or TSIG key authenticated hosts dynamic updates are allowed or denied.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses, networks, and/or Infoblox::DNS::TSIGKey objects. To deny updates, add "!" as a prefix to IP addresses and/or networks. Specify "any" to allow updates from any IP address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get allow update list
my $allow_update_list = $grid_dns->allow_update();
#Modify allow update list
$grid_dns->allow_update(["any"]);

#Creating a TSIG key object.
my $update_key1 = $session->gen_tsig_key();

my $up_key1 = Infoblox::DNS::TSIGKey->new(
    name => "update_key",
    key  => $update_key1
    );

#Modify allow update list
$grid_dns->allow_update(["10.0.0.10", "20.0.0.0/24","2008::129b","!"."30.0.0.30", $up_key1,
"!"."40.10.0.0/24","!"."2004::76bc/64"]);
#Use Infoblox::Grid::NamedACL
$grid_dns->allow_update($nacl);
```

anonymize_response_logging( )

Use this method to set or retrieve the flag that indicates whether the anonymization of captured DNS responses is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable anonymization of captured DNS response or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get anonymize_response_logging value
my $anonymize_response_logging = $object->anonymize_response_logging();

#Modify anonymize_response_logging value
$object->anonymize_response_logging('true');
```

attack_mitigation( )

Use this method to set or retrieve mitigation settings for DNS attacks.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::AttackMitigation object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attack_mitigation value
my $attack_mitigation   $grid_dns  attack_mitigation
```

```
                          =          ->                    ();
#Modify attack_mitigation
$grid_dns->attack_mitigation($attack_mitigation);
```

auto_blackhole( )

Use this method to set or retrieve the auto blackhole settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::AutoBlackHole object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get auto_blackhole value
my $auto_blackhole = $grid_dns->auto_blackhole();
#Modify auto_blackhole
$grid_dns->auto_blackhole($auto_blackhole);
```

bind_check_names_policy( )

Use this method to set or retrieve the BIND check names policy, which indicates the action the appliance takes when it encounters host names that do not comply with the Strict Hostname Checking policy. This method applies only if the host name restriction policy is set to "Strict Hostname Checking".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The allowed values of the parameter are "fail", "warn" or undefined. This indicates the desired BIND behavior in the case of illegal hostnames. The default value is undefined, which means the appliance ignores illegal hostnames.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bind_check_names_policy value
my $names_policy = $grid_dns->bind_check_names_policy();
#Modify bind_check_names_policy
$grid_dns->bind_check_names_policy("warn");
```

bind_hostname_directive( )

Use this method to set or retrieve the value of BIND 'hostname' directive.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are "NONE" and "HOSTNAME". The default value is "NONE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bind_hostname_directive
my $bind_hostname_directive = $grid_dns->bind_hostname_directive();
#Modify bind_hostname_directive
$grid_dns->bind_hostname_directive("HOSTNAME");
```

blackhole_list( )

Use this method to set or retrieve the blackhole list of a grid DNS object. This list specifies the IP addresses and networks from which the DNS queries are blocked.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPV4/IPv6 addresses and networks. To allow queries, add "!" as the prefix to the IP addresses and networks. Specify "any" to block DNS queries from any IP address.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get the blackhole list
my $blackhole_list = $grid_dns->blackhole_list();
#Modify the blackhole_list
$grid_dns->blackhole_list(["any"]);
#Modify the blackhole list
$grid_dns->blackhole_list(["10.0.0.10",
"20.0.0.0/24","2010::256/64","!"."2011::23cb/64","!"."30.0.0.30", "!"."40.10.0.0/24"]);
#Modify the blackhole list
$grid_dns->blackhole_list(undef);
#Use Infoblox::Grid::NamedACL
$grid_dns->blackhole_list($nacl);
```

blacklist_action( )

Use this method to specify the action to perform when a domain name matches the pattern defined in a rule that is specified by the blacklist_ruleset method.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "REDIRECT" or "REFUSE". The default value is "REFUSE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Examples

```
#Get blacklist_action
my $blacklist_action = $grid_dns->blacklist_action();
#Modify blacklist_action
$grid_dns->blacklist_action("REDIRECT");
```

blacklist_log_query( )

Use this method to set or retrieve the flag that indicates whether blacklist redirection queries are logged.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable logging, or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_log_query
my $blacklist_log_query = $grid_dns->nxdomain_log_query( );
#Modify blacklist_log_query
$grid_dns->blacklist_log_query("true");
```

blacklist_redirect_addresses( )

Use this method to specify the IP addresses the appliance includes in the response it sends in place of a blacklisted IP address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of IPv4 addresses. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_redirect_addresses
my $blacklist_redirect_addresses = $grid_dns->blacklist_redirect_addresses( );
#Modify blacklist_redirect_addresses
$grid_dns->blacklist_redirect_addresses(["10.0.0.10", "10.0.0.20"]);
```

blacklist_redirect_ttl( )

Use this method to set or retrieve the TTL value of the synthetic DNS response that result from blacklist redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the TTL in seconds. The default value is 60.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_redirect_ttl
my $blacklist_redirect_ttl = $grid_dns->blacklist_redirect_ttl( );
#Modify blacklist_redirect_ttl
$grid_dns->blacklist_redirect_ttl(60);
```

blacklist_rulesets( )

Use this method to specify or retrieve Infoblox::DNS::Ruleset object names assigned at the grid level for blacklist redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains the names of the Infoblox::DNS::Ruleset objects assigned to the grid. The names must be in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_rulesets
my $blacklist_rulesets = $grid_dns->blacklist_rulesets();
#Modify blacklist_rulesets
$grid_dns->blacklist_rulesets(["ruleset1", "ruleset2"]);
```

bulk_host_name_template( )

Use this method to set or retrieve the default bulk host name format of a grid DNS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of a valid bulk host name format.

For instance, if the prefix of a bulk host is *info*, the IP address range is *213.19.32.133-213.19.32.134*, and the domain name is *infoblox.com*. If the bulk host name template "Three Octets" is set at the grid level, then the bulk host names will be *info-213-19-*

23-133.infoblox.com and *info-213-19-23-134.infoblox.com*.

If the bulk host name template specified is "CustomerTemplate"(*#3*#4), the bulk host names will be *info*023*133.infoblox.com* and *info-023-134.infoblox.com*.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the bulk host name format
my $grid_template = $grid_dns->bulk_host_name_template();
#Modify bulk host name format
$grid_dns->bulk_host_name_template("Three Octets");
```

bulk_host_name_templates( )

Use this method to set or retrieve the list of bulk host name templates.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::DNS::BulkHostNameTemplate object(s).

There are four Infoblox predefined bulk host name templates.

Template Name Template Format

"Four Octets" -$1-$2-$3-$4

"Three Octets" -$2-$3-$4

"Two Octets" -$3-$4

"One Octet" -$4

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bulk_host_name_templates
my $bulk_host_name_templates = $grid_dns->bulk_host_name_templates();

#Modify bulk_host_name_templates

#Constructing four out-of-box bulk host name templates
my $four_octets = Infoblox::Grid::DNS::BulkHostNameTemplate->new(
    template_name   => "Four Octets",
    template_format => '-$1-$2-$3-$4'
);
my $three_octets = Infoblox::Grid::DNS::BulkHostNameTemplate->new(
    template_name   => "Three Octets",
    template_format => '-$2-$3-$4'
);
my $two_octets = Infoblox::Grid::DNS::BulkHostNameTemplate->new(
    template_name   => "Two Octets",
    template_format => '-$3-$4'
);
my $one_octet = Infoblox::Grid::DNS::BulkHostNameTemplate->new(
    template_name   => "One Octet",
    template_format => '-$4'
);

#Creating a new bulk host name templates.
my $custom_template = Infoblox::Grid::DNS::BulkHostNameTemplate->new(
    template_name   => "Custom Template",
    template_format => '-#1-#2-#3-#4'
);

$grid_dns->bulk_host_name_templates([$custom_template, $four_octets, $three_octets, $two_octets,
$one_octet]);
```

capture_dns_queries_on_all_domains( )

Use this method to set or retrieve the flag that indicates whether the capturing of DNS queries for all domains is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable capturing of DNS queries for all domains or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get capture_dns_queries_on_all_domains value
my $capture_dns_queries_on_all_domains = $object->capture_dns_queries_on_all_domains();

#Modify capture_dns_queries_on_all_domains value
$object->capture_dns_queries_on_all_domains('true');
```

client_subnet_domains( )

Use this method to set or retrieve the list of zone domain names that are allowed or forbidden for EDNS client subnet (ECS) recursion.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::DNS::ClientSubnetDomain objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get client_subnet_domains value
my $value = $grid_dns->client_subnet_domains();

#Construct Infoblox::Grid::DNS::ClientSubnetDomain object
my $object = Infoblox::Grid::ClientSubnetDomain->new(
    domain     => 'domain.com',
    permission => 'DENY',
);

#Modify client_subnet_domains value
$grid_dns->client_subnet_domains([$object]);
```

client_subnet_ipv4_prefix_length( )

Use this method to set or retrieve the default IPv4 source prefix length used when sending queries with EDNS client subnet option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 32.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get client_subnet_ipv4_prefix_length value
my $value = $object->client_subnet_ipv4_prefix_length();

#Modify client_subnet_ipv4_prefix_length value
$object->client_subnet_ipv4_prefix_length(30);
```

client_subnet_ipv6_prefix_length( )

Use this method to set or retrieve the default IPv6 source prefix length used when sending queries with EDNS client subnet option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 128.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get client_subnet_ipv6_prefix_length value
my $value = $object->client_subnet_ipv6_prefix_length();

#Modify client_subnet_ipv6_prefix_length value
$object->client_subnet_ipv6_prefix_length(30);
```

copy_xfer_to_notify( )

Use this method to enable/disable copying of the allowed IPs from zone transfer list into also-notify statement in named.conf.

Parameter

Set the parameter to "true" to enable copying of the allowed IPs from zone transfer list into also-notify statement in named.conf. Set the parameter to "false" to disable it.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->copy_xfer_to_notify();
# Modify attribute value
$grid_dns->copy_xfer_to_notify('true');
```

ddns_force_creation_timestamp_update( )

Use this method to set or retrieve the flag that indicates whether the creation timestamp of resource records (RR) should be updated when DDNS update happens even if there is no change to the RR.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to update the creation timestamp of RR on every DDNS update, and 'false' to update the creation timestamp only when RR changes during a DDNS update. The default is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_force_creation_timestamp_update value
$value = $object->ddns_force_creation_timestamp_update();

#modify ddns_force_creation_timestamp_update value
$object->ddns_force_creation_timestamp_update('true');
```

ddns_restrict_patterns_list( )

Use this method to set or retrieve an unordered list of restriction patterns for an option of to restrict DDNS updates based on FQDN patterns.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of FQDNs in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get ddns_restrict_patterns_list value
$ddns_restrict_patterns_list = $grid_dns->ddns_restrict_patterns_list();

#modify ddns_restrict_patterns_list value
$grid_dns->ddns_restrict_patterns_list(['foo.com', 'bar.com']);
```

ddns_restrict_patterns( )

Use this method to set or retrieve the flag which indicates whether an option to restrict DDNS update request based on FQDN patterns is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DDNS update request restriction base on FQDN patterns and 'false to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get ddns_restrict_patterns value
$ddns_restrict_patterns = $grid_dns->ddns_restrict_patterns();

#modify ddns_restrict_patterns value
$grid_dns->ddns_restrict_patterns('true');
```

ddns_restrict_static( )

Use this method to set or retrieve the flag which indicates whether an option to restrict DDNS update request to resource records which are marked as 'STATIC' is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DDNS update requests to resource records which are marked as 'STATIC' and 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get ddns_restrict_static value
$ddns_restrict_static = $grid_dns->ddns_restrict_static();

#modify ddns_restrict_static value
$grid_dns->ddns_restrict_static('true');
```

ddns_restrict_protected( )

Use this method to set or retrieve the flag which indicates whether an option to restrict DDNS update request to protected resource records is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DDNS update requests to protected resource records and 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get ddns_restrict_protected value
$ddns_restrict_protected = $grid_dns->ddns_restrict_protected();

#modify ddns_restrict_protected value
$grid_dns->ddns_restrict_protected('true');
```

ddns_restrict_secure( )

Use this method to set or retrieve the flag which indicates whether DDNS update request for principal other than target resource record's principal is restricted.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DDNS update requests restriction for principal other than target resource record's principal and 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get ddns_restrict_secure value
$ddns_restrict_secure = $grid_dns->ddns_restrict_secure();

#modify ddns_restrict_secure value
$grid_dns->ddns_restrict_secure('true');
```

ddns_principal_tracking( )

Use this method to set or retrieve the flag which indicates whether the DDNS principal track is enabled or disabled.

DDNS principal tracking includes putting them into resource record affected by update.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DDNS principal tracking and 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get ddns_principal_tracking value
$ddns_principal_tracking = $grid_dns->ddns_principal_tracking();

#modify ddns_principal_tracking value
$grid_dns->ddns_principal_tracking('true');
```

ddns_principal_group( )

Use this method to set or retrieve the DDNS principal group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::DNS::DDNS::PrincipalCluster::Group object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get ddns_principal_group value
$ddns_principal_group = $grid_dns->ddns_principal_group();

#modify ddns_principal_group value
$grid_dns->ddns_principal_group($principal_group);
```

default_ttl( )

Use this method to set or retrieve the default TTL value of a grid DNS object. This interval tells the secondary how long the data can be cached.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number for the TTL, in seconds. *Default* value is 1/2 of lease time or 28800 seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the default TTL
my $default_ttl = $grid_dns->default_ttl();
#Modify the default TTL
$grid_dns->default_ttl(28800);
```

disable_edns( )

Use this method to enable or disable EDNS0 support for queries that require recursive resolution.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to disable EDNS0 or "false" to enable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the double confirmation of zone deletion flag
my $disable_edns = $grid_dns->disable_edns();
#Modify disable_edns flag
$grid_dns->disable_edns("true");
```

dns_cache_acceleration_ttl( )

Use this method to set or retrieve the minimum TTL value, in seconds, that a DNS record must have in order for it to be cached by the DNS Cache Acceleration service.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An integer from 1 to 65000 that represents the TTL in seconds. The default value is 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_cache_acceleration_ttl
my $dns_cache_acceleration_ttl = $grid_dns->dns_cache_acceleration_ttl( );
#Modify dns_cache_acceleration_ttl
$grid_dns->dns_cache_acceleration_ttl(60);
```

dns_health_check_anycast_control( )

Use this method to set or retrieve the flag that indicates whether the anycast failure (BFD session down) is enabled on member failure or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable anycast failure on Member failure, and 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_anycast_control value
my $value = $object->dns_health_check_anycast_control();

#Modify dns_health_check_anycast_control value
$object->dns_health_check_anycast_control('true');
```

dns_health_check_domain_list( )

Use this method to set or retrieve the list of domain names for the DNS health check.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains desired domain names in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_domain_list value
my $value = $object->dns_health_check_domain_list();

#Modify dns_health_check_domain_list value
$object->dns_health_check_domain_list(['foo.com', 'bar.net']);
```

dns_health_check_interval( )

Use this method to set or retrieve the time interval (in seconds) for DNS health check.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 10 and 21600 that represents number of seconds between two health checks.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_interval value
my $value = $object->dns_health_check_interval();

#Modify dns_health_check_interval value
$object->dns_health_check_interval(2000);
```

dns_health_check_recursion_flag( )

Use this method to set or retrieve the flag that indicates whether the recursive DNS health check is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable recursive DNS health check queries, and 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_recursion_flag value
my $value = $object->dns_health_check_recursion_flag();

#Modify dns_health_check_recursion_flag value
$object->dns_health_check_recursion_flag('true');
```

dns_health_check_retries( )

Use this method to set or retrieve the number of DNS health check retries.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_retries value
my $value = $object->dns_health_check_retries();

#Modify dns_health_check_retries value
$object->dns_health_check_retries(2);
```

dns_health_check_timeout( )

Use this method to set or retrieve the DNS health check timeout interval (in seconds).

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_timeout value
my $value = $object->dns_health_check_timeout();

#Modify dns_health_check_timeout value
$object->dns_health_check_timeout(10);
```

dns_query_capture_file_time_limit( )

Use this method to set or retrieve the time limit (in minutes) for the DNS query capture file.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is unsigned integer between 1 and 10. The default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_query_capture_file_time_limit value
my $dns_query_capture_file_time_limit = $object->dns_query_capture_file_time_limit();

#Modify dns_query_capture_file_time_limit value
$object->dns_query_capture_file_time_limit('5');
```

dns64_groups( )

Use this method to set or retrieve the list of DNS64 synthesis groups.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::DNS::DNS64Group objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the list of DNS64 synthesis groups
my $dns64_groups_list = $grid_dns->dns64_groups();

#Modify it
my $group = $session->get(
                        object => "Infoblox::Grid::DNS::DNS64Group"),
                        name => "groupname",
                        prefix => "groupprefix",
                      );
$grid_dns->dns64_groups([$group]);
```

dnssec_enabled( )

Use this method to enable/disable the DNS security extension.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to enable the DNS security extension. Set the parameter to "false" to disable the feature.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_enabled
my $dnssec_enabled = $grid_dns->dnssec_enabled();
#Modify dnssec_enabled
$grid_dns->dnssec_enabled("true");
```

dnssec_enable_ksk_auto_rollover( )

Use this method to enable automatic rollover for Key-signing key.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable automatic rollover for Key-signing key or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_enable_ksk_auto_rollover value
my $enable_ksk_auto_rollover = $grid_dns->dnssec_enable_ksk_auto_rollover();
#Modify dnssec_enable_ksk_auto_rollover value
$grid_dns->dnssec_enable_ksk_auto_rollover("true");
```

dnssec_expired_signatures_enabled( )

Use this method to control whether the DNS grid object accepts expired signatures.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to accept expired signatures. Set the parameter to "false" to reject expired signatures.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_expired_signatures_enabled
my $dnssec_expired_signatures_enabled = $grid_dns->dnssec_expired_signatures_enabled();
#Modify dnssec_expired_signatures_enabled
$grid_dns->dnssec_expired_signatures_enabled("true");
```

dnssec_ksk_algorithms( )

Use this method to set or retrieve the DNSSEC key-signing key algorithms of all the zones in the grid.

This property determines which algorithms to use when generating the keys for signing the DNSKEY records.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Currently there are two major versions of the DNSSEC zone encryption mechanism. The difference between the two is in their implementation of the Next Secure (NSEC) records. The older version, which is referred to as NSEC, is based on RFCs 4033-4035. The newer version, which is referred to as NSEC3, is described in RFC 5155.

The valid value is a list containing Infoblox::DNS::DNSSecKeyAlgorithm objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting algorithm
my $algorithms = $grid_dns->dnssec_ksk_algorithms();

# Modifying algorithm
$grid_dns->dnssec_ksk_algorithm([$alg1, $alg2]);
```

dnssec_ksk_email_notification_enabled( )

Use this method to enable or disable email notifications for KSK related events.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable email notification or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_ksk_email_notification_enabled value
my $value = $grid_dns->dnssec_ksk_email_notification_enabled();
#Modify dnssec_ksk_email_notification_enabled value
$grid_dns->dnssec_ksk_email_notification_enabled("true");
```

dnssec_ksk_rollover_interval()

Use this method to set or retrieve the rollover interval of the KSK keys.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A positive integer that specifies the number of seconds between KSK rollovers. Normally, this parameter should be larger than the ZSK rollover interval. The DNSSEC key-signing key rollover interval (in seconds) must be between 1 day and seconds to Jan 2, 2038.

The default value of the dnssec_ksk_rollover_interval parameter is 31536000 (1 year).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting dnssec_ksk_rollover_interval
my $ksk_rollover = $grid_dns->dnssec_ksk_rollover_interval();

# Modifying dnssec_ksk_rollover_interval
$grid_dns->dnssec_ksk_rollover_interval(86400);
```

dnssec_ksk_rollover_notification_config( )

Use this method to determine the type of events users will be notified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are "NONE", "ALL" and "REQUIRE_MANUAL_INTERVENTION". Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_ksk_rollover_notification_config value
my $value = $grid_dns->dnssec_ksk_rollover_notification_config();
#Modify dnssec_ksk_rollover_notification_config value
$grid_dns->dnssec_ksk_rollover_notification_config("ALL");
```

dnssec_ksk_snmp_notification_enabled( )

Use this method to enable or disable SNMP notifiations for KSK related events.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable SNMP notification or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_ksk_snmp_notification_enabled value
my $value = $grid_dns->dnssec_ksk_snmp_notification_enabled();
#Modify dnssec_ksk_snmp_notification_enabled value
$grid_dns->dnssec_ksk_snmp_notification_enabled("true");
```

dnssec_negative_trust_anchors( )

Use this method to set or retrive the list of zones for which the appliance does not perform DNSSEC validation.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of strings that contains the list of zones for which the appliance does not perform DNSSEC validation.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_negative_trust_anchors value
my $value = $grid_dns->dnssec_negative_trust_anchors();
#Modify dnssec_negative_trust_anchors value
$grid_dns->dnssec_negative_trust_anchors($zones);
```

dnssec_nsec3_iterations( )

Use this method to define the number of iterations for NSEC3 hashing.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value are integers between 0 and 65535. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_nsec3_iterations value
my $iteration = $grid_dns->dnssec_nsec3_iterations();
#Modify dnssec_nsec3_iterations value
$grid_dns->dnssec_nsec3_iterations();
```

dnssec_nsec3_salt_min_length( )

Use this method to define the minimum length for the NSEC3 salt.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value are integers between 0 and 65535. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_nsec3_salt_min_length value
my $salt_min_length = $grid_dns->dnssec_nsec3_salt_min_length();
#Modify dnssec_nsec3_salt_min_length value
$grid_dns->dnssec_nsec3_salt_min_length();
```

dnssec_nsec3_salt_max_length( )

Use this method to define the maximum length for the NSEC3 salt.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value are integers between 0 and 65535. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_nsec3_salt_max_length value
my $salt_max_length = $grid_dns->dnssec_nsec3_salt_max_length();
#Modify dnssec_nsec3_salt_max_length value
$grid_dns->dnssec_nsec3_salt_max_length();
```

dnssec_signature_expiration( )

Use this method to set or retrieve the expiration time for DNSSEC signatures.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The signature expiration time in seconds. The minimum value is 86400 (1 day), the maximum value is the number of seconds from the time you set it to January 2038.

The default value of dnssec_signature_expiration parameter is 2592000 seconds (i.e. 30 days).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting dnssec_signature_expiration
my $signature_expiration = $grid_dns->dnssec_signature_expiration();

# Modifying dnssec_signature_expiration
$grid_dns->dnssec_signature_expiration(31536000);
```

dnssec_validation_enabled( )

Use this method to enable and disable DNS security validation (for the grid appliances working as clients of secure zones).

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to enable the validation. Set to "false" to disable the validation.

The default value of the parameter is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_validation_enabled
my $dnssec_validation_enabled = $grid_dns->dnssec_validation_enabled();
#Modify dnssec_validation_enabled
$grid_dns->dnssec_validation_enabled("false");
```

dnssec_blacklist_enabled()

Use this method to enable and disable blacklist rules for DNSSEC-enabled clients.

Parameter

Set the parameter to "true" to apply blacklist rules for DNSSEC-enabled clients. Set to "false" to disable them.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_blacklist_enabled
my $dnssec_blacklist_enabled = $grid_dns->dnssec_blacklist_enabled();
#Modify dnssec_blacklist_enabled
$grid_dns->dnssec_blacklist_enabled("true");
```

dnssec_dns64_enabled()

Use this method to enable and disable DNS64 groups for DNSSEC-enabled clients.

Parameter

Set the parameter to "true" to apply DNS64 groups for DNSSEC-enabled clients. Set to "false" to disable them.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_dns64_enabled
my $dnssec_dns64_enabled = $grid_dns->dnssec_dns64_enabled();
#Modify dnssec_dns64_enabled
$grid_dns->dnssec_dns64_enabled("true");
```

dnssec_nxdomain_enabled()

Use this method to enable and disable NXDOMAIN rules for DNSSEC-enabled clients.

Parameter

Set the parameter to "true" to apply NXDOMAIN rules for DNSSEC-enabled clients. Set to "false" to disable them.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_nxdomain_enabled
my $dnssec_nxdomain_enabled = $grid_dns->dnssec_nxdomain_enabled();
#Modify dnssec_nxdomain_enabled
$grid_dns->dnssec_nxdomain_enabled("true");
```

dnssec_rpz_enabled()

Use this method to enable and disable RPZ policies for DNSSEC-enabled clients.

Parameter

Set the parameter to "true" to apply RPZ policies for DNSSEC-enabled clients. Set to "false" to disable them.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_rpz_enabled
my $dnssec_rpz_enabled = $grid_dns->dnssec_rpz_enabled();
#Modify dnssec_rpz_enabled
$grid_dns->dnssec_rpz_enabled("true");
```

dnssec_trusted_keys( )

Use this method to specify the list of trusted keys for the DNSSEC feature.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Array reference that contains a list of Infoblox::DNS::DnssecTrustedKey objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns a reference to a list of the trusted keys.

Example

```
#Get dnssec_trusted_keys
my $dnssec_trusted_keys = $grid_dns->dnssec_trusted_keys();
#Modify dnssec_trusted_keys
my $key1=Infoblox::DNS::DnssecTrustedKey->new(
   fqdn => "myzone.com",
   algorithm => "RSAMD5",
   key       => "c2ltcGxlIGtleQo="
   );
$grid_dns->dnssec_trusted_keys([$key1]);
```

dnssec_zsk_algorithms( )

Use this method to set or retrieve the DNSSEC zone-signing key algorithms of all the zones in the grid.

This property determines which algorithms to use when generating the keys for signing the DNSKEY records.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Currently there are two major versions of the DNSSEC zone encryption mechanism. The difference between the two is in their implementation of the Next Secure (NSEC) records. The older version, which is referred to as NSEC, is based on RFCs 4033-4035. The newer version, which is referred to as NSEC3, is described in RFC 5155.

The valid value is a list containing Infoblox::DNS::DNSSecKeyAlgorithm objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting algorithms
my $algorithms = $grid_dns->dnssec_zsk_algorithms();

# Modifying algorithms
$grid_dns->dnssec_zsk_algorithm([$alg1, $alg2]);
```

dnssec_zsk_rollover_interval()

Use this method to set or retrieve the zone-signing key rollover interval.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A positive integer that specifies the number of seconds between ZSK rollovers. Normally, this parameter should be smaller than the KSK rollover interval. The DNSSEC zone-signing key over interval (in seconds) must be between 1 day and the number of seconds from present to Jan 2038.

The default value of the dnssec_zsk_rollover_interval parameter is 2592000 seconds (30 days).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting dnssec_zsk_rollover_interval
my $zsk_rollover = $grid_dns->dnssec_zsk_rollover_interval();

# Modifying dnssec_ksk_rollover_interval
$grid_dns->dnssec_zsk_rollover_interval(86400);
```

dnssec_zsk_rollover_mechanism( )

Use this method to set or retrieve the ZSK rollover mechanism type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are "DOUBLE_SIGN" and "PRE_PUBLISH". Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_zsk_rollover_mechanism value
my $value = $grid_dns->dnssec_zsk_rollover_mechanism();
#Modify dnssec_zsk_rollover_mechanism value
$grid_dns->dnssec_zsk_rollover_mechanism("DOUBLE_SIGN");
```

domains_to_capture_dns_queries( )

Use this method to set or retrieve the list of domains to capture DNS queries.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains desired domain names in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domains_to_capture_dns_queries value
my $domains_to_capture_dns_queries = $object->domains_to_capture_dns_queries();

#Modify domains_to_capture_dns_queries value
$object->domains_to_capture_dns_queries(['domain1.com', 'domain2.com']);
```

dtc_dnssec_mode( )

Use this method to set or retrieve the DTC DNSSEC operation mode.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'SIGNED' and 'UNSIGNED'. The default value is 'UNSIGNED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dtc_dnssec_mode value
my $dtc dnssec mode   $object  dtc dnssec mode
```

```
                        =       ->              ();
```

```
#Modify dtc_dnssec_mode value
$object->dtc_dnssec_mode('UNSIGNED');
```

dtc_edns_prefer_client_subnet( )

Use this method to set or retrieve the flag that indicates whether the use of the edns-client-subnet option for DTC is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable use of the edns-client-subnet option for DTC or 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dtc_edns_prefer_client_subnet value
my $dtc_edns_prefer_client_subnet = $object->dtc_edns_prefer_client_subnet();

#Modify dtc_edns_prefer_client_subnet value
$object->dtc_edns_prefer_client_subnet('true');
```

dtc_topology_ea_list( )

Use this method to set or retrieve the DTC topology extensible attribute definition list. When configuring a DTC topology, users may configure classification as either "Geographic" or "Extensible Attributes". Selecting "Extensible Attributes" will replace supported MaxMind database labels (Continent, Country, Subdivision, City) with the names of the selected EA types and provide values of those extensible attributes extracted from DHCP Network Container, Network and Range objects.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ExtensibleAttributeDef object name.

Note that the number of extensible attribute definitions is limited to 4. You can select only string, enum, and integer extensible attribute definitions.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dtc_topology_ea_list value
my $dtc_topology_ea_list = $object->dtc_topology_ea_list();

#Modify dtc_topology_ea_list value
$object->dtc_topology_ea_list(['Site', 'State']);
```

email( )

Use this method to set or retrieve the email address of a grid DNS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

String with email address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get email address
my $email = $grid_dns->email();
```

```
#Modify email address
$grid_dns->email("admin\@infoblox.com");
```

enable_blackhole( )

Use this method to set or retrieve the enable_blackhole flag of a grid DNS object. When enabled, the Infoblox appliance does not respond to DNS queries from clients that are in the configured blackhole_list.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_blackhole flag or "false" to deactivate and unset it. The default value is "false".

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_blackhole flag
my $enable_blackhole = $grid_dns->enable_blackhole();
#Modify enable_blackhole recursive query flag
$grid_dns->enable_blackhole("true");
```

enable_blacklist( )

Use this method to enable or disable a blacklist globaly.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_blacklist flag or "false" to deactivate/unset it. The default is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_blacklist
my $enable_blacklist = $grid_dns->enable_blacklist( );
#Modifying enable_blacklist
$grid_dns->enable_blacklist("true");
```

enable_capture_dns_queries( )

Use this method to set or retrieve the flag that indicates whether the capture of DNS queries is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the capture of DNS queries or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_capture_dns_queries value
my $enable_capture_dns_queries = $object->enable_capture_dns_queries();

#Modify enable_capture_dns_queries value
$object->enable_capture_dns_queries('true');
```

enable_capture_dns_responses( )

Use this method to set or retrieve the flag that indicates whether the capture of DNS responses is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the capture of DNS responses or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_capture_dns_responses value
my $enable_capture_dns_responses = $object->enable_capture_dns_responses();

#Modify enable_capture_dns_responses value
$object->enable_capture_dns_responses('true');
```

enable_client_subnet_recursive( )

Use this method to set or retrieve the flag that indicates whether adding EDNS client subnet options in recursive resolutions is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable adding EDNS client subnet options in recursive resolutions or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_client_subnet_recursive value
my $value = $object->enable_client_subnet_recursive();

#Modify enable_client_subnet_recursive value
$object->enable_client_subnet_recursive('true');
```

enable_client_subnet_forwarding( )

Use this method to set or retrieve the flag that indicates whether forwarding EDNS client subnet options to upstream servers is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable forwarding of EDNS client subnet options to upstream servers or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_client_subnet_forwarding value
my $value = $object->enable_client_subnet_forwarding();

#Modify enable_client_subnet_forwarding value
$object->enable_client_subnet_forwarding('true');
```

enable_delete_associated_ptr( )

Use this method to enable or disable the ability to automatically remove associated PTR records while deleting A or AAAA records.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the ability to automatically remove associated PTR records while deleting A or AAAA records or "false" to disable it. The default value is "false".

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_delete_associated_ptr flag
my $enable_delete_associated_ptr = $grid_dns->enable_delete_associated_ptr();
#Modify enable_delete_associated_ptr flag
$grid_dns->enable_delete_associated_ptr("true");
```

enable_dns_health_check( )

Use this method to set or retrieve the flag that indicates whether the DNS health check is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DNS health check, and 'false' to disable it.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dns_health_check value
my $value = $object->enable_dns_health_check();

#Modify enable_dns_health_check value
$object->enable_dns_health_check('true');
```

enable_dns64( )

Use this method to enable/disable DNS64 support.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_dns64 flag or "false" to deactivate and unset it. The default value is "false".

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dns64 flag
my $enable_dns64 = $grid_dns->enable_dns64();
#Modify enable_dns64 recursive query flag
$grid_dns->enable_dns64("true");
```

enable_dtc_dns_fall_through( )

Use this method to set or retrieve the flag that indicates whether the DNS traffic control (DTC) to DNS fall through is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DTC to DNS fall through or 'false' to disable it.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method

returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dtc_dns_fall_through value
my $value = $grid_dns->enable_dtc_dns_fall_through();

#Modify enable_dtc_dns_fall_through value
$grid_dns->enable_dtc_dns_fall_through('false');
```

enable_excluded_domain_names( )

Use this method to set or retrieve the flag that indicates whether the excluding domain names from captured DNS query and response is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the excluding domain names from captured DNS query and response or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_excluded_domain_names value
my $enable_excluded_domain_names = $object->enable_excluded_domain_names();

#Modify enable_excluded_domain_names value
$object->enable_excluded_domain_names('true');
```

enable_fixed_rrset_order_fqdns( )

Use this method to enable or disable fixed RRset order for specified FQDNs.

The enable_fixed_rrset_order_fqdns attribute can be specified explicitly. It is also set implicitly when fixed_rrset_order_fqdns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable fixed RRset order for specified FQDNs or "false" to disable it.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_fixed_rrset_order_fqdns flag
my $enable_fixed_rrset_order_fqdns = $grid_dns->enable_fixed_rrset_order_fqdns();
#Modify enable_fixed_rrset_order_fqdns flag
$grid_dns->enable_fixed_rrset_order_fqdns("true");
```

enable_ftc( )

Use this method to set or retrieve the flag that indicates whether the Fault Tolerant Caching (FTC) feature is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the FTC feature or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ftc
my $enable_ftc = $grid_dns->enable_ftc();
#Modify enable_ftc
$grid_dns->enable_ftc('true');
```

enable_gss_tsig( )

Use this method to enable/disable the appliance to receive GSS-TSIG authenticated updates from DHCP clients. You must import the keytab file before you enable this feature. See Infoblox::Session->import_data().

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the the appliance to receive GSS-TSIG authenticated updates or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_gss_tsig value
$my $enable_gss_tsig = $grid_dns->enable_gss_tsig();

#Modify enable_gss_tsig value

$session->import_data(
     type        => 'keytab',
     path        => '/infoblox/tests/datasets/gss-tsig-gs.keytab',
     service     => 'dns',
     virtual_ip  => '192.168.1.2');

$grid_dns->enable_gss_tsig('true');
```

enable_host_rrset_order( )

Use this method to set or retrieve the grid-level enable_host_rrset_order value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_host_rrset_order flag or "false" to deactivate and unset it. The default value is "false".

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_host_rrset_order
my $host_rrset_order = $grid_dns->enable_host_rrset_order();
# Set enable_host_rrset_order
$grid_dns->enable_host_rrset_order("true");
```

enable_hsm_signing( )

Use this method to enable/disable the HSM for DNSSEC key generation and signing. To enable this feature, an HSM group must be configured with at least one enabled HSM.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable HSM signing or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_hsm_signing
$grid_dns->enable_hsm_signing( );
#Modify enable_hsm_signing
$grid_dns->enable_hsm_signing("true");
```

enable_query_rewrite( )

Use this method to enable or disable DNS query rewrite.

Parameter

Specify "true" to enable DNS query rewrite or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_query_rewrite
$grid_dns->enable_query_rewrite( );
#Modify enable_query_rewrite
$grid_dns->enable_query_rewrite("true");
```

excluded_domain_names( )

Use this method to set or retrieve the list of domains that are excluded from DNS response and query capturing.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains desired domain names in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get excluded_domain_names value
my $excluded_domain_names = $object->excluded_domain_names();

#Modify excluded_domain_names value
$object->excluded_domain_names(['domain1.com', 'domain2.com']);
```

expire_after( )

Use this method to set or retrieve the expiration time of a grid DNS object. If the secondary DNS server fails to contact the primary server for the specified interval, the secondary server stops giving out answers about the zone because the zone data is too old to be useful.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number with the seconds for the expiration time. *Default* value is 2419200 seconds (4 weeks).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the expiration time
my $expire_after = $grid_dns->expire_after();
#Modify the expiration time
$grid_dns->expire_after(2419200);
```

file_transfer_setting( )

Use this method to set or retrieve the DNS capture file transfer settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::FileTransferSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get file_transfer_setting value
my $file_transfer_setting = $object->file_transfer_setting();

#Modify file_transfer_setting value
$object->file_transfer_setting($file_transfer);
```

filter_aaaa( )

Use this method to set or retrieve the type of AAAA filtering for this grid DNS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "YES", "NO" and "BREAK_DNSSEC". The default value is "NO".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the filter aaaa type
my $filter_aaaa = $grid_dns->filter_aaaa();
#Modify the filtering
$grid_dns->filter_aaaa("YES");
```

filter_aaaa_list( )

Use this method to set or retrieve the list of IPv4 addresses and networks from which queries are received. AAAA filtering is applied to these addresses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4 addresses and networks. To return AAAA records for queries received from an IPv4 client, add "!" as the prefix to the IP addresses and networks. Specify "any" to allow AAAA records to be returned for any query received by an IPv4 client.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get the filter_aaaa list
my $filter_aaaa_list = $grid_dns->filter_aaaa_list();
#Modify the filter_aaaa_list
$grid_dns->filter_aaaa_list(["any"]);
#Modify the filter_aaaa list
$grid_dns->filter_aaaa_list(["10.0.0.10", "20.0.0.0/24", "!"."30.0.0.30", "!"."40.10.0.0/24"]);
#Modify the filter_aaaa list
$grid_dns->filter_aaaa_list(undef);
#Use Infoblox::Grid::NamedACL
```

```
$grid_dns->filter_aaaa_list($nacl);
```

forward_only( )

Use this method to set or retrieve the forward only flag of a grid DNS object. On enabling, the Infoblox appliance will send queries to forwarders only, and not to internal or Internet root servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the forward_only flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the forward only flag
my $forward_only = $grid_dns->forward_only();
#Modify the forward only
$grid_dns->forward_only("true");
```

forward_updates( )

Use this method to set or retrieve the forward_updates flag of a grid DNS object. This enables a secondary server to receive updates from the DHCP server, and then forward them to the primary DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the forward_updates flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the forward updates flag
my $forward_updates = $grid_dns->forward_updates();
#Modify the forward updates flag
$grid_dns->forward_updates("true");
```

forwarders( )

Use this method to set or retrieve the forwarders list of a grid DNS object. A forwarder is essentially a name server to which other name servers first send all of their off-site queries. The forwarder builds up a cache of information, avoiding the necessity for the other name servers to send queries off-site.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains IP address(es).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the forwarders list
my $forwarders_list = $grid_dns->forwarders();
#Modify the forwarders list
$grid_dns->forwarders(["2.2.2.2", "3.3.3.3"]);
```

fixed_rrset_order_fqdns( )

Use this method to set or retrieve configuration for fixed RRSET order for specified FQDNs.

Setting this method to a defined value implicitly sets the enable_fixed_rrset_order_fqdns method to "true". Setting the parameter to undefined causes the appliance to disable fixed RRset order of FQDNs and automatically resets the enable_fixed_rrset_order_fqdns method to "false".

Note that when fixed_rrset_order_fqdns is set to a defined value and enable_fixed_rrset_order_fqdns is set to "false", the last operation takes precedence. Thus the sequence $object->fixed_rrset_order_fqdns($fqdns); $object->enable_fixed_rrset_order_fqdns("false"); will set enable_fixed_rrset_order_fqdns to "false", and the sequence $object->enable_fixed_rrset_order_fqdns("false"); $object->fixed_rrset_order_fqdns($fqdns); will result in enable_fixed_rrset_order_fqdns="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::DNS::FixedRRSetOrderFQDN objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the fixed_rrset_order_fqdns list
my $fixed_rrset_order_fqdns = $grid_dns->fixed_rrset_order_fqdns();
#Modify the fixed_rrset_order_fqdns list
$grid_dns->fixed_rrset_order_fqdns([$fqdn1, $fqdn2]);
```

ftc_expired_record_ttl( )

Use this method to set or retrieve the TTL value of the expired Fault Tolerant Caching (FTC) record in DNS responses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the TTL in seconds. The default value is 5.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ftc_expired_record_ttl
my $ftc_expired_record_ttl = $grid_dns->ftc_expired_record_ttl( );
#Modify ftc_expired_record_ttl
$grid_dns->ftc_expired_record_ttl(60);
```

ftc_expired_record_timeout( )

Use this method to set or retrieve the timeout value after which the expired Fault Tolerant Caching (FTC) record becomes stale and is no longer valid.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the timeout in seconds. The default value is 86400.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ftc_expired_record_timeout
my $ftc_expired_record_timeout = $grid_dns->ftc_expired_record_timeout( );
#Modify ftc_expired_record_timeout
$grid_dns->ftc_expired_record_timeout(3600);
```

gss_tsig_keys( )

Use this method to set or retrieve the list of Kerberos keys for a Grid DNS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::KerberosKey objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the Kerberos keys list
my $kerberos_keys_list = $grid_dns->gss_tsig_keys();
#Modify the Kerberos keys list
my $kerberos_key1 = Infoblox::Cluster::KerberosKey->new(
       principal => 'host/appliance.ivan.test1@LADYBUG.LOCAL',
       );
my $kerberos_key2 = Infoblox::Cluster::KerberosKey->new(
       principal => 'host/appliance.ivan.test2@LADYBUG.LOCAL',
       );
$grid_dns->gss_tsig_keys([$kerberos_key1, $kerberos_key2]);
```

host_name_restriction_policy( )

Use this method to set or retrieve the default host name restriction policy of a grid DNS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

String with the name of predefined record policies or user-defined record policies. The default value is the predefined record policy "Allow Underscore".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get host name restriction policy
my $host_name_restriction_policy = $grid_dns->host_name_restriction_policy();
#Modify host name restriction policy
$grid_dns->host_name_restriction_policy("Allow Any");
```

lame_ttl( )

Use this method to set or retrieve the number of seconds to cache lame delegations or lame servers.

Parameter

The number of seconds to cache lame delegations or lame servers. The default value is 600.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lame_ttl
my $lame_ttl = $grid_dns->lame_ttl();
#Modify lame_ttl
$grid_dns->lame_ttl(700);
```

logging_categories( )

Use this method to set or retrieve the logging categories. It is possible to specify several BIND logging message categories to be captured by syslog.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains one or more of the following values:

"general" - Records the BIND messages that are not specifically classified.

"config" - Records the parsing messages of the configuration file.

"dnssec" - Records the DNSSEC-signed responses.

"network" - Records the network operation messages.

"queries" - Records the query messages.

"query_rewrite" - Records rewritten queries.

"responses" - Records the response messages.

"security" - Records the approved and denied requests.

"xfer-in" - Records zone transfer messages from the remote name servers to the appliance.

"xfer-out" - Records zone transfer messages from the Infoblox appliance to remote name servers.

"update" - Records the dynamic update instances.

"resolver" - Records the DNS resolution instances, including recursive queries from resolvers.

"notify" - Records the asynchronous zone change notification messages.

"lame_servers" - Records bad delegation instances.

"database" - Records BIND internal database processes.

"client" - Records client requests.

"rpz" - Records RPZ messages.

"dtc_gslb" - Records the DTC GSLB activity.

"dtc_health" - Records the DTC health monitoring.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the logging categories list
my $logging_categories_list = $grid_dns->logging_categories();
#Modify the logging categories list
$grid_dns->logging_categories(["general", "database", "queries"]);
```

logging_facility( )

Use this method to set or retrieve the logging facility of a grid DNS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Text with the facility name. Valid values are: "daemon", "local0", "local1", "local2", "local3", "local4", "local5", "local6", and "local7".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the logging facility
my $logging_facility = $grid_dns->logging_facility();
#Modify the logging facility
$grid_dns->logging_facility("daemon");
```

max_cache_ttl( )

Use this method to set or retrieve the maximum time (in seconds) for which the server will cache positive answers.

Parameter

The maximum time is specified in seconds. The default value is 604800.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_cache_ttl
my $max_cache_ttl = $grid_dns->max_cache_ttl();
#Modify max_cache_ttl
$grid_dns->max_cache_ttl(400);
```

max_ncache_ttl( )

Use this method to set or retrieve the maximum time (in seconds) for which the server will cache negative (NXDOMAIN) responses.

Parameter

The maximum time is specified in seconds. The default value is 10800. The maximum allowed value is 604800.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_ncache_ttl
my $max_ncache_ttl = $grid_dns->max_ncache_ttl();
#Modify max_ncache_ttl
$grid_dns->max_ncache_ttl(400);
```

max_cached_lifetime( )

Use this method to set or retrieve maximum time in seconds a DNS response can be stored in the hardware acceleration cache.

Parameter

Valid values are unsigned integer between 60 and 86400, inclusive. Default value is 86400.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_cached_lifetime
my $max_cached_lifetime = $grid_dns->max_cached_lifetime();
#Modify max_cached_lifetime
$grid_dns->max_cached_lifetime(400);
```

member_secondary_notify( )

Use this method to set or retrieve the member_secondary_notify flag of a grid DNS object. When enabled, this feature allows grid members that are authoritative secondary servers to send notification messages to external name servers, if the grid member that is primary for a zone fails or loses connectivity.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set member_secondary_notify flag or "false" to deactivate/unset it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the member secondary notification flag
my $member_secondary_notify = $grid_dns->member_secondary_notify();
#Modify the member secondary notification flag
$grid_dns->member_secondary_notify("false");
```

negative_ttl( )

Use this method to set or retrieve the negative TTL value of a grid DNS object. This interval tells the secondary how long data can be cached for "Does Not Respond" responses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number for the negative TTL, in seconds. *Default* value is 900 seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the negative ttl value
my $negative_ttl = $grid_dns->negative_ttl();
#Modify the negative ttl value
$grid_dns->negative_ttl(800);
```

next_secure_type( )

Use this method to set or retrieve resource record type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is 'NSEC' or 'NSEC3'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the next_secure_type value
my $next_secure_type = $grid_dns->next_secure_type();
#Modify the next_secure_type value
$grid_dns->next_secure_type('NSEC3');
```

notify_delay( )

Use this method to specify with how many seconds of delay the notify messages are sent to secondaries.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are unsigned integer between 5 and 86400, inclusive. Default value is 5.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting notify_delay
my $notify_delay = $griddns->notify_delay( );
#Modifying notify_delay
$griddns->notify_delay(5);
```

nxdomain_redirect( )

Use this method to enable or disable NXDOMAIN redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the nxdomain_redirect flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting nxdomain_redirect
my $nxdomain_redirect = $griddns->nxdomain_redirect( );
#Modifying nxdomain_redirect
$griddns->nxdomain_redirect("true");
```

nxdomain_redirect_addresses( )

Use this method to set the NXDOMAIN redirection addresses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of IPv4 addresses. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_redirect_addresses
my $nxdomain_redirect_addresses = $griddns->nxdomain_redirect_addresses( );
#Modify nxdomain_redirect_addresses
$griddns->nxdomain_redirect_addresses(["10.0.0.10", "10.0.0.20"]);
```

nxdomain_redirect_addresses_ipv6( )

Use this method to set the NXDOMAIN redirection IPv6 addresses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of IPv6 addresses. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_redirect_addresses_ipv6
my $nxdomain_redirect_addresses_ipv6 = $griddns->nxdomain_redirect_addresses_ipv6( );
#Modify nxdomain_redirect_addresses_ipv6
$griddns->nxdomain_redirect_addresses_ipv6(["2001:db8::1", "2002:ffff::1"]);
```

nxdomain_redirect_ttl( )

Use this method to set or retrieve the TTL value of synthetic DNS responses that result from NXDOMAIN redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the TTL in seconds. The default value is 60.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_redirect_ttl
my $nxdomain_redirect_ttl = $griddns->nxdomain_redirect_ttl( );
#Modify nxdomain_redirect_ttl
$griddns->nxdomain_redirect_ttl(60);
```

nxdomain_log_query( )

Use this method to set or retrieve the flag that indicates whether NXDOMAIN redirection queries are logged.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable logging, or "false" to deactivate it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_log_query
my $nxdomain_log_query = $griddns->nxdomain_log_query( );
#Modify nxdomain_log_query
$griddns->nxdomain_log_query("true");
```

nxdomain_rulesets( )

Use this method to specify or retrieve Infoblox::DNS::Ruleset object names assigned at the grid level for NXDOMAIN redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains the names of the Infoblox::DNS::Ruleset objects assigned to the grid. The names must be in string format. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_rulesets
my $nxdomain_rulesets = $griddns->nxdomain_rulesets();
#Modify nxdomain_rulesets
$griddns->nxdomain_rulesets(["ruleset1", "ruleset2"]);
```

notify_source_port( )

Use this method to set or retrieve the source port number for notify messages. When requesting zone transfers from the primary server, some secondary DNS servers use the source port number (the primary server used to send the notify message) as the destination port number in the zone transfer request.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Source port number for notify messages. Valid values are between 1 and 63999. *Default* is picked by BIND.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the notify source port value
```

```
my $notify_source_port = $grid_dns->notify_source_port();
#Modify the notify source port value
$grid_dns->notify_source_port(77);
```

nsgroup_default( )

Use this method to set or retrieve the default nameserver group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Text with the name of the default nameserver group. *Default* value is None.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the default nameserver group
my $nsgroup_default = $grid_dns->nsgroup_default();
#Modify the default nameserver group
$grid_dns->nsgroup_default("ns_group_A");
```

nsgroups( )

Use this method to set or retrieve the list of nameserver groups. A name server group is a collection of one primary DNS server and one or more secondary DNS servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::DNS::Nsgroup and Infoblox::DNS::Member object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the nameserver group
my $nsgroup = $grid_dns->nsgroups();
#Modify the nameserver group
#Creating Member objects.
my $member1 = Infoblox::DNS::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
    stealth  => "false"
    );

#Creating a nameserver object.
my $nameserver1 = Infoblox::DNS::Nameserver->new(
    name     => "ns1.test.extra",
    ipv4addr => "4.4.4.4",
    stealth  => "false",
    TSIGname => "tsig_name",
    TSIGkey  => "ZX1jVJl7C58GT/sc7Q3ucA=="
    );

#Creating a nameserver object.
my $nameserver2 = Infoblox::DNS::Nameserver->new(
    name     => "ns2.test.extra",
    ipv4addr => "5.5.5.5",
    stealth  => "false",
    TSIGname => "tsig_name2",
    TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
    );

my $nsg1 = Infoblox::Grid::DNS::Nsgroup->new(
    name        => "ns_group_A",
    primary     => $member1,
    secondaries => [$nameserver1, $nameserver2]
```

```
    );

$grid_dns->nsgroups([$nsg1]);
```

preserve_host_rrset_order_on_secondaries( )

Use this method to set or retrieve the grid-level preserve_host_rrset_order_on_secondaries value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the preserve_host_rrset_order_on_secondaries flag or "false" to unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get preserve_host_rrset_order_on_secondaries
my $preserve_order = $griddns->preserve_host_rrset_order_on_secondaries();
# Set preserve_host_rrset_order_on_secondaries
$griddns->preserve_host_rrset_order_on_secondaries("true");
```

query_source_port( )

Use this method to set or retrieve the query source port of a grid DNS object. Specifying a source port number for recursive queries ensures that a firewall will allow the response.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Source port number for recursive queries . Valid values are between 1 and 63999. *Default* is picked by BIND.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the query source port
my $query_source_port = $grid_dns->query_source_port();
#Modify the query source port
$grid_dns->query_source_port(99);
```

query_rewrite_prefix( )

Use this method to set or retrieve the domain name prefix for DNS query rewrite.

Parameter

Valid value is the domain name prefix in string format. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get query_rewrite_prefix
my $query_rewrite_prefix = $grid_dns->query_rewrite_prefix();
#Modify query_rewrite_prefix
$grid_dns->query_rewrite_prefix("user-ersgcds");
```

query_rewrite_domain_names( )

Use this method to set or retrieve the list of domain names that trigger DNS query rewrite.

Parameter

Valid value is an array reference that contains domain names in string format. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get query_rewrite_domain_names
my $query_rewrite_domain_names = $grid_dns->query_rewrite_domain_names();
#Modify query_rewrite_domain_names
$grid_dns->query_rewrite_domain_names(["florida.south", "florida.west"]);
```

scavenging_settings( )

Use this method to set or retrieve the Grid-level scavenging settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::ScavengingSetting object.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get scavenging_settings value
my $scavenging_settings = $object->scavenging_settings();

#Modify scavenging_settings value
$object->scavenging_settings($scavenging_settings);
```

record_name_policies( )

Use this method to set or retrieve the list of record name policies.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::RecordNamePolicy object(s). By default there are three predefined policies.

Policy Name Regex Applied

"Allow Any" .+

"Allow Underscore" ^[-a-zA-Z0-9_.]+$

"Strict Hostname Checking" ^[a-zA-Z0-9]$|^[a-zA-Z0-9][-a-zA-Z0-9.]*[a-zA-Z0-9]$

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get record name policies
my $record_name_policies = $grid_dns->record_name_policies();
#Modify record_name_policies

#Creating record name policy objects.
my $recpolicy1 = Infoblox::Grid::RecordNamePolicy->new(
    regex => "*",
    name  => "Local Policy",
    );
my $recpolicy2 = Infoblox::Grid::RecordNamePolicy->new(
    regex => ".+",
    name  => "Allow Any",
    );
```

```
my $recpolicy3 = Infoblox::Grid::RecordNamePolicy->new(
    regex => "^[-a-zA-Z0-9_.]+\$",
    name  => "Allow Underscore",
    );
my $recpolicy4 = Infoblox::Grid::RecordNamePolicy->new(
    regex => "^[a-zA-Z0-9]\$|^[a-zA-Z0-9][-a-zA-Z0-9.]*[a-zA-Z0-9]\$",
    name  => "Strict Hostname Checking",
    );

$grid_dns->record_name_policies([$recpolicy1, $recpolicy2, $recpolicy3, $recpolicy4]);
```

recursive_query_list( )

Use this method to set or retrieve the recursive query list of a Grid DNS object. This list specifies from which IP addresses, networks and TSIG key authenticated clients recursive queries are allowed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses, networks, and/or Infoblox::DNS::TSIGKey objects. To deny queries, add "!" as a prefix to IP addresses and/or networks. Specify "any" to allow recursive queries from any IP address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the recursive query list
my $recursive_query_list = $grid_dns->recursive_query_list();
#Modify the recursive query list
$grid_dns->recursive_query_list(["any"]);

#Creating a TSIG key object
my $tsig_key2 = $session->gen_tsig_key();

my $key2 = Infoblox::DNS::TSIGKey->new(
    name => "rcl_key",
    key  => $tsig_key2
    );
#Modify the recursive query list
$grid_dns->recursive_query_list(["10.0.0.10", "20.0.0.0/24","2010::256/64", $key2,
"!"."2011::23cb/64","!"."30.0.0.30", "!"."40.10.0.0/24"]);
#Modify the recursive query list
$grid_dns->recursive_query_list(undef);
#Use Infoblox::Grid::NamedACL
$grid_dns->recursive_query_list($nacl);
```

refresh_timer( )

Use this method to set or retrieve the refresh time. This interval tells the secondary how often to send a message to the primary for a zone to check that its data is current, and retrieve fresh data if it is not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number with the seconds for the refresh time. *Default* value is 10800 seconds (3 hours).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the refresh time
my $refresh_timer = $grid_dns->refresh_timer();
#Modify the refresh time
$grid_dns->refresh_timer(108);
```

resolver_query_timeout( )

Use this method to set or retrieve recursive query timeout.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer that contains the recursive query time (in seconds) for the resolver.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get resolver_query_timeout
my $resolver_query_timeout = $grid_dns->resolver_query_timeout();
#Modify resolver_query_timeout
$grid_dns->resolver_query_timeout(29);
```

response_rate_limiting( )

Use this method to set or retrieve response rate limiting settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::ResponseRateLimiting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get response_rate_limiting
my $response_rate_limiting = $grid_dns->response_rate_limiting();
#Modify response_rate_limiting
$grid_dns->response_rate_limiting($response_rate_limiting);
```

restart_setting( )

Use this method to set or retrive Grid DNS service restart settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ServiceRestart object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get restart_setting
my $restart_setting = $grid_dns->restart_setting();
#Modify the retry time
$grid_dns->restart_setting($restart_setting);
```

retry_timer( )

Use this method to set or retrieve the retry time. This interval tells the secondary how long to wait before attempting to recontact the primary after a connection failure occurs between the two servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number with the seconds for the retry time. *Default* value is 3600 seconds (1 hour).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the retry time
my $retry_timer = $grid_dns->retry_timer();
#Modify the retry time
$grid_dns->retry_timer(360);
```

rootNS( )

Use this method to set or retrieve the list of customized root nameserver(s). You can use Internet root name servers or specify host names and IP addresses of custom root name servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::RootNameServer object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the root nameserver list
my $rootNS_list = $grid_dns->rootNS();
#Modify the root nameserver list
#Creating RootNameServer objects.
my $rootns1 = Infoblox::Grid::RootNameServer->new(
    ipv4addr  => "44.44.44.44",
    host_name => "test1.com",
    );

my $rootns2 = Infoblox::Grid::RootNameServer->new(
    ipv4addr  => "55.5.5.5",
    host_name => "test2.com",
    );

$grid_dns->rootNS([$rootns1, $rootns2]);
```

serial_query_rate( )

Use this method to set or retrieve the number of maximum concurrent SOA queries per second for the Grid.

Parameter

Valid values are unsigned integer between 20 and 1000, inclusive. Default value is 20.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->serial_query_rate();
# Modify attribute value
$grid_dns->serial_query_rate(30);
```

server_id_directive( )

Use this method to set or retrieve the value for the BIND and UNBOUND 'server-id' directive.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are "NONE" and "HOSTNAME". The default value is "NONE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get server_id_directive
my $server_id_directive = $grid_dns->server_id_directive();
#Modify server_id_directive
$grid_dns->server_id_directive("HOSTNAME");
```

sortlist( )

Use this method to set or retrieve the sort list of a grid DNS object. A sort list sorts the order of addresses in responses made to DNS queries.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::DNS::Sortlist object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the sort list
my $sortlist = $grid_dns->sortlist();
#Modify the sort list
#Creating a SortList object.
my $sort1 = Infoblox::DNS::Sortlist->new(
    match_list      => ["10.20.1.0/24", "10.20.2.0/24"],
    source_ipv4addr => "1.2.3.4"
    );

$grid_dns->sortlist([$sort1]);
```

store_locally( )

Use this method to set or retrieve the flag that indicates whether the storing of query capture reports on the appliance is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable storing of query capture reports on the appliance or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get store_locally value
my $store_locally = $object->store_locally();

#Modify store_locally value
$object->store_locally('true');
```

transfer_excluded_servers( )

Use this method to set or retrieve the list of excluded servers for zone transfers of a grid DNS object. This list exclude the specified DNS servers during zone transfers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains IP addresses of DNS servers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the transfer excluded server list
my $transfer_excluded_servers = $grid_dns->transfer_excluded_servers();
#Modify the transfer excluded server list
$grid_dns->transfer_excluded_servers(["10.0.0.10", "20.0.0.0"]);
```

transfer_format( )

Use this method to set or retrieve the zone transfer format. The zone transfer format determines the BIND format for a zone transfer. This provides tracking capabilities for single or multiple transfers and their associated servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is one of the following:

"many_answers" - Includes as many records as the packet size allows.

"one_answer" - Includes one record per packet.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the zone transfer format
my $transfer_format = $grid_dns->transfer_format();
#Modify the zone transfer format
$grid_dns->transfer_format("many_answers");
```

transfers_in( )

Use this method to set or retrieve the number of maximum concurrent transfers for the Grid.

Parameter

Valid values are unsigned integer between 10 and 100, inclusive. Default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->transfers_in();
# Modify attribute value
$grid_dns->transfers_in(20);
```

transfers_out( )

Use this method to set or retrieve the number of maximum outbound concurrent zone transfers for the Grid.

Parameter

Valid values are unsigned integers between 1 and 100, inclusive. The default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->transfers_out();
# Modify attribute value
```

```
$grid_dns->transfers_out(20);
```

transfers_per_ns( )

Use this method to set or retrieve the number of maximum concurrent transfers per member for the Grid.

Parameter

Valid values are unsigned integer between 2 and 100, inclusive. Default value is 2.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->transfers_per_ns();
# Modify attribute value
$grid_dns->transfers_per_ns(3);
```

rpz_disable_nsdname_nsip( )

Use this method to set or retrieve the option to disable NSDNAME and NSIP resource records from RPZ feeds.

Parameter

Specify "true" to enable the filter (to filter out NSDNAME and NSIP resource records). Specify "false" to disable the filter. Valid values are "true" or "false". Default value is "false".

Returns

If you specify a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->rpz_disable_nsdname_nsip();
# Modify attribute value
$grid_dns->rpz_disable_nsdname_nsip("true");
```

rpz_drop_ip_rule_enabled( )

Use this method to set or retreive the flag that indicates whether the DNS server ignores RPZ-IP triggers with large prefix lengths or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable ignoring of RPZ-IP triggers with large prefix lengths or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->rpz_drop_ip_rule_enabled();
# Modify attribute value
$grid_dns->rpz_drop_ip_rule_enabled("true");
```

rpz_drop_ip_rule_min_prefix_length_ipv4( )

Use this method to set or retreive minimum prefix length for IPv4 RPZ-IP triggers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 31 that represents prefix length (in bits) for IPv4 RPZ-IP triggers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->rpz_drop_ip_rule_min_prefix_length_ipv4();
# Modify attribute value
$grid_dns->rpz_drop_ip_rule_min_prefix_length_ipv4("16");
```

rpz_drop_ip_rule_min_prefix_length_ipv6( )

Use this method to set or retreive minimum prefix length for IPv6 RPZ-IP triggers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 127 that represents prefix length (in bits) for IPv6 RPZ-IP triggers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->rpz_drop_ip_rule_min_prefix_length_ipv6();
# Modify attribute value
$grid_dns->rpz_drop_ip_rule_min_prefix_length_ipv6("120");
```

rpz_qname_wait_recurse( )

Use this method to enable or disable recursive RPZ lookups.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable recursive RPZ lookups or "false" to disable them. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_dns->rpz_qname_wait_recurse();
# Modify attribute value
$grid_dns->rpz_qname_wait_recurse("true");
```

zone_deletion_double_confirm( )

Use this method to enable or disable double confirmation during zone deletion.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the zone_deletion_double_confirm flag or "false" to deactivate/unset it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the double confirmation of zone deletion flag
my $zone_deletion_double_confirm = $grid_dns->zone_deletion_double_confirm();
```

```
#Modify the double confirmation of zone deletion flag
$grid_dns->zone_deletion_double_confirm("false");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as get and modify. This sample code also includes error handling for the operations.

#Preparation prior to getting and modifying a grid DNS object

```
use strict;
use Infoblox;

#Creating a session to appliance.
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
    );
unless( $session ){
    die("Constructor for session failed:",
    Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print" Session object created successfully \n";

#Creating RootNameServer objects.
my $rootns1 = Infoblox::Grid::RootNameServer->new(
    ipv4addr  => "44.44.44.44",
    host_name => "test1.com",
    );
unless( $rootns1 ){
    die("Constructor for rootnameserver1 failed:",
    Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print" Rootnameserver1 object created successfully \n";

my $rootns2 = Infoblox::Grid::RootNameServer->new(
    ipv4addr  => "55.5.5.5",
    host_name => "test2.com",
    );
unless( $rootns2 ){
    die("Constructor for rootnameserver2 failed:",
    Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print" Rootnameserver2 object created successfully \n";

#Creating Transfer Key objects.
my $key1 = Infoblox::DNS::TSIGKey->new(
    name => "tsig_xfer",
    key  => ":2xCOMPAT"
    );
unless( $key1 ){
    die("Constructor for transfer key \(key1\) failed:",
    Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print" Transfer key object \(key1\) created successfully \n";

my $tsig_key1 = $session->gen_tsig_key();
unless( $tsig_key1 ){
    die("Generate tsig_key1 failed: ",
    $session->status_code() . ":" . $session->status_detail());
}

my $key2 = Infoblox::DNS::TSIGKey->new(
    name => "transfer_key",
    key  => $tsig_key1
    );
unless( $key2 ){
    die("Constructor for transfer key \(key2\) failed:",
    Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print" Transfer key object \(key2\) created successfully \n";

#Creating Update Key object.
my $update_key1 = $session->gen_tsig_key();
```

```
unless( $update_key1 ){
    die("Generate update_key1 failed:",
    $session->status_code() . ":" . $session->status_detail());
}

my $up_key1 = Infoblox::DNS::TSIGKey->new(
    name => "update_key",
    key  => $update_key1
    );
unless( $up_key1 ){
    die("Constructor for update key failed: ",
    Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print" Update key object created successfully \n";

#Creating a SortList object.
my $sort1 = Infoblox::DNS::Sortlist->new(
    match_list      => ["10.20.1.0/24", "10.20.2.0/24"],
    source_ipv4addr => "1.2.3.4"
    );
unless( $sort1 ){
    die("Constructor for sortlist failed: ",
    Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print" Sortlist object created successfully \n";
```

#Get and modify the DNS object

```
#Getting the DNS object from appliance through session.
my @result = $session->get(
    object => "Infoblox::Grid::DNS",
    name   => "Infoblox"
    );
unless( @result ){
    die("Get grid DNS failed: ",
    $session->status_code() . ":" . $session->status_detail());
}
print" Get grid DNS object found at least 1 matching entry \n";

my $grid_dns = $result[0];
if ($grid_dns) {

#Modifying the value of the specified object
   $grid_dns->allow_query(["10.0.0.10", "20.0.0.0/24", "!" . "30.0.0.30", "!" . "40.10.0.0/24"]);
   $grid_dns->allow_recursive_query("true");
   $grid_dns->allow_transfer(["10.0.0.10", "20.0.0.0/24", $key1, "!"."30.0.0.30", "!"."40.10.0.0/24",
$key2]);
   $grid_dns->allow_update(["10.0.0.10", "20.0.0.0/24", "!"."30.0.0.30", "!"."40.10.0.0/24", $up_key1]);
   $grid_dns->default_ttl(28800);
   $grid_dns->expire_after(2419200);
   $grid_dns->forwarders(["2.2.2.2", "3.3.3.3"]);
   $grid_dns->logging_facility("daemon");
   $grid_dns->negative_ttl(900);
   $grid_dns->recursive_query_list(["10.0.0.10", "20.0.0.0/24", "!" . "30.0.0.30", "!" . "40.10.0.0/24"]);
   $grid_dns->refresh_timer(10800);
   $grid_dns->retry_timer(3600);
   $grid_dns->rootNS([$rootns1, $rootns2]);
   $grid_dns->sortlist([$sort1]);
   $grid_dns->transfer_excluded_servers(["10.0.0.10", "20.0.0.0"]);
   $grid_dns->transfer_format("many_answers");

 #Applying the changes
 my $response = $session->modify($grid_dns);
 unless( $response ){
    die("Modify grid DNS failed: ",
    $session->status_code() . ":" . $session->status_detail());
 }
 print" Modify grid DNS successful \n";
  }
  else {
   print "No grid DNS object found.";
  }

####PROGRAM ENDS####

NAME

Infoblox::Grid::DNS::AllNsgroups - All NS Groups object.

DESCRIPTION

The All NS Groups object is a generic nameserver group object that provides information about all nameserver groups.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific nameserver group object:

 name    - Optional. The nameserver group name in a string format.
 comment - Optional. The nameserver group comment in a string format.
 type    - Optional. The nameserver group type in a string format.
```

Examples

```
my @retrieved_objs = $session->get(
    object  => 'Infoblox::Grid::DNS::AllNsgroups',
    name    => 'ns_group_a',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for the object:

 name    - Optional. The nameserver group name in a string format (regexp).
 comment - Optional. The nameserver group comment in a string format (regexp).
 type    - Optional. The nameserver group type in a string format (exact).
```

Examples

```
# search for objects
my @retrieved_objs = $session->search(
    object       => 'Infoblox::Grid::DNS::AllNsgroups',
    name         => 'ns_.*',
    comment      => '.*comment',
);
```

METHODS

This section describes all the methods that you can use to retrieve the attribute values of a nameserver group.

comment( )

Use this method to retrieve the nameserver group descriptive comment. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get comment value
my $comment = $object->comment();
```

name( )

Use this method to retrieve the nameserver group name. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();
```

type( )

Use this method to retrieve the nameserver group type. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'AUTH', 'FORWARDING_MEMBER', 'STUB_MEMBER', 'DELEGATION', 'FORWARD_STUB_SERVER'.

Example

```
#Get type value
my $type = $object->type();
```

NAME

Infoblox::Grid::DNS::AttackDetect - a DNS Attack Detect object.

DESCRIPTION

The DNS Attack Detect object provides information about DNS attack detection settings.

CONSTRUCTOR

```
my $attack_detect = Infoblox::Grid::DNS::AttackDetect->new(
    enable        => 'true' | 'false', # Optional
    high          => $uint,            # Optional
    interval_max  => $uint,            # Optional
    interval_min  => $uint,            # Optional
    interval_time => $uint,            # Optional
    low           => $uint,            # Optional
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

Infoblox::Grid::DNS::AttackMitigation->detect_chr( )

Use this method to set or retrieve configuration for the Cache Hit Ratio (CHR) changes detection. See Infoblox::Grid::DNS::AttackMitigation->detect_chr() for parameters and return values.

Example

```
#Get detect_chr value
my $detect_chr = $attack_mitigation->detect_chr();
#Modify detect_chr
$attack_mitigation->detect_chr($detect_chr);
```

Infoblox::Grid::DNS::AttackMitigation->detect_nxdomain_responses( )

Use this method to set or retrieve configuration for the recursive queries NXDOMAIN responses detection. See Infoblox::Grid::DNS::AttackMitigation->detect_nxdomain_responses() for parameters and return values.

Example

```
#Get detect_nxdomain_responses value
my $detect_nxdomain_responses = $attack_mitigation->detect_nxdomain_responses();
#Modify detect_nxdomain_responses
$attack_mitigation->detect_nxdomain_responses($detect_nxdomain_responses);
```

Infoblox::Grid::DNS::AttackMitigation->detect_udp_drop( )

Use this method to set or retrieve configuration for the UDP packet drop rate detection. See Infoblox::Grid::DNS::AttackMitigation->detect_udp_drop() for parameters and return values.

Example

```
#Get detect_udp_drop value
my $detect_udp_drop = $attack_mitigation->detect_udp_drop();
#Modify detect_udp_drop
$attack_mitigation->detect_udp_drop($detect_udp_drop);
```

METHODS

enabled( )

Use this method to enable or disable DNS attack detection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DNS attack detection or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable value
my $enable = $attack_detect->enable();
#Modify enable
$attack_detect->enable('true');
```

high( )

Use this method to set or retrieve the high threshold value (in percentage) for starting DNS attack detection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 0 and 100.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high value
my $high = $attack_detect->high();
#Modify high
$attack_detect->high(90);
```

interval_max( )

Use this method to set or retrieve the maximum number of events that have occurred before processing DNS attack detection.

Note that detection processing occurs each time when interval_max events have occurred or at least interval_min events have occurred and at least interval_time seconds have elapsed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interval_max value
my $interval_max = $attack_detect->interval_max();
#Modify interval_max
$attack_detect->interval_max(100000);
```

interval_min( )

Use this method to set or retrieve the minimum number of events that have occurred before processing DNS attack detection.

Note that detection processing occurs each time when interval_max events have occurred or at least interval_min events have occurred and at least interval_time seconds have elapsed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interval_min value
my $interval_min = $attack_detect->interval_min();
#Modify interval_min
$attack_detect->interval_min(1000);
```

interval_time( )

Use this method to set or retrieve the time interval between detection processing.

Note that detection processing occurs each time when interval_max events have occurred or at least interval_min events have occurred and at least interval_time seconds have elapsed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interval_time value
my $interval_time = $attack_detect->interval_time();
#Modify interval_time
$attack_detect->interval_time(10);
```

low( )

Use this method to set or retrieve the low threshold value (in percentage) for starting DNS attack detection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 0 and 100.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low value
my $low = $attack_detect->low();
#Modify low
$attack_detect->low(40);
```

NAME

Infoblox::Grid::DNS::AttackMitigation - a DNS Attack Mitigation object.

DESCRIPTION

The DNS Attack Mitigation object provides information about mitigation configuration for DNS attacks.

CONSTRUCTOR

```
my $attack_mitigation = Infoblox::Grid::DNS::AttackMitigation->new(
    detect_chr                => $attack_detect,    # Optional
    detect_chr_grace          => $uint,             # Optional
    detect_nxdomain_responses => $attack_detect,    # Optional
    detect_udp_drop           => $attack_detect,    # Optional
    interval                  => $uint,             # Optional
    mitigate_nxdomain_lru     => 'true' | 'false', # Optional
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions can be applied to a DNS Attack Mitigation object.

Infoblox::Grid::DNS->attack_mitigation( )

Use this method to set or retrieve mitigation settings for DNS attacks. See Infoblox::Grid::DNS->attack_mitigation() for parameters and return values.

Example

```
#Get attack_mitigation value
my $attack_mitigation = $grid_dns->attack_mitigation();
#Modify attack_mitigation
$grid_dns->attack_mitigation($attack_mitigation);
```

Infoblox::Grid::Member::DNS->attack_mitigation( )

Use this method to set or retrieve mitigation settings for DNS attacks on the member. See Infoblox::Grid::Member::DNS->attack_mitigation() for parameters and return values.

Example

```
#Get attack_mitigation value
my $attack_mitigation = $member_dns->attack_mitigation();
#Modify attack_mitigation
```

```
$member_dns->attack_mitigation($attack_mitigation);
```

METHODS

detect_chr( )

Use this method to set or retrieve configuration for the Cache Hit Ratio (CHR) changes detection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::AttackDetect object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get detect_chr value
my $detect_chr = $attack_mitigation->detect_chr();
#Modify detect_chr
$attack_mitigation->detect_chr($detect_chr);
```

detect_chr_grace( )

Use this method to set or retrieve the cache usage (in percentage) when Cache Hit Ratio (CHR) detection starts.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 0 and 100.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get detect_chr_grace value
my $detect_chr_grace = $attack_mitigation->detect_chr_grace();
#Modify detect_chr_grace
$attack_mitigation->detect_chr_grace(50);
```

detect_nxdomain_responses( )

Use this method to set or retrieve configuration for the recursive queries NXDOMAIN responses detection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::AttackDetect object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get detect_nxdomain_responses value
my $detect_nxdomain_responses = $attack_mitigation->detect_nxdomain_responses();
#Modify detect_nxdomain_responses
$attack_mitigation->detect_nxdomain_responses($detect_nxdomain_responses);
```

detect_udp_drop( )

Use this method to set or retrieve configuration for the UDP packet drop rate detection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::AttackDetect object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get detect_udp_drop value
my $detect_udp_drop = $attack_mitigation->detect_udp_drop();
#Modify detect_udp_drop
$attack_mitigation->detect_udp_drop($detect_udp_drop);
```

interval( )

Use this method to set or retrieve the minimum time interval (in seconds) between changes in attack status.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interval value
my $interval = $attack_mitigation->interval();
#Modify interval
$attack_mitigation->interval(50);
```

mitigate_nxdomain_lru( )

Use this method to enable or disable impact mitigation of NXDOMAIN responses in cache by tracking NXDOMAIN entries.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable impact mitigation of NXDOMAIN responses, or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mitigate_nxdomain_lru value
my $mitigate_nxdomain_lru = $attack_mitigation->mitigate_nxdomain_lru();
#Modify mitigate_nxdomain_lru
$attack_mitigation->mitigate_nxdomain_lru('true');
```

NAME

Infoblox::Grid::DNS::AutoBlackHole - a DNS Auto Blackhole object.

DESCRIPTION

The DNS Auto Blackhole object provides information about DNS auto blackhole configuration.

CONSTRUCTOR

```
my $auto_blackhole = Infoblox::Grid::DNS::AutoBlackHole->new(
        enable_fetches_per_server => 'true' | 'false', # Optional
        enable_fetches_per_zone   => 'true' | 'false', # Optional
        enable_holddown           => 'true' | 'false', # Optional
        fetches_per_server        => $uint,            # Optional
        fetches_per_zone          => $uint,            # Optional
        fps_freq                  => $uint,            # Optional
        holddown                  => $uint,            # Optional
        holddown_timeout          => $uint,            # Optional
        holddown_threshold        => $uint,            # Optional
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions can be applied to a DNS Auto Blackhole object.

Infoblox::Grid::DNS->auto_blackhole( )

Use this method to set or retrieve the auto blackhole settings. See Infoblox::Grid::DNS->auto_blackhole() for parameters and return values.

Example

```
#Get auto_blackhole value
my $auto_blackhole = $grid_dns->auto_blackhole();
#Modify bind_check_auto_blackhole
$grid_dns->auto_blackhole($auto_blackhole);
```

Infoblox::Grid::Member::DNS->auto_blackhole( )

Use this method to set or retrieve the auto blackhole settings on the member. See Infoblox::Grid::Member::DNS->auto_blackhole() for

paparameters and return values.

Example

```
#Get auto_blackhole value
my $auto_blackhole = $member_dns->auto_blackhole();
#Modify auto_blackhole
$member_dns->auto_blackhole($auto_blackhole);
```

METHODS

enable_fetches_per_server( )

Use this method to enable or disable the maximum number of concurrent recursive queries sent to each upstream DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the maximum number of concurrent recursive queries sent to each upstream DNS server or 'false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_fetches_per_server value
my $enable_fetches_per_server = $auto_blackhole->enable_fetches_per_server();
#Modify enable_fetches_per_server
$auto_blackhole->enable_fetches_per_server('true');
```

enable_fetches_per_zone( )

Use this method to enable or disable the maximum number of concurrent recursive queries sent to each DNS zone.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the maximum number of concurrent recursive queries sent to each DNS zone or 'false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_fetches_per_zone value
my $enable_fetches_per_zone = $auto_blackhole->enable_fetches_per_zone();
#Modify enable_fetches_per_zone
$auto_blackhole->enable_fetches_per_zone('true');
```

enable_holddown( )

Use this method to enable or disable the holddown for non-responsive servers for a specified time interval.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the holddown for non-responsive servers or 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_holddown value
my $enable_holddown = $auto_blackhole->enable_holddown();
```

```
#Modify enable_holddown
$auto_blackhole->enable_holddown('true');
```

fetches_per_server( )

Use this method to set or retrieve the maximum number of concurrent recursive queries for each DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get fetches_per_server value
my $fetches_per_server = $auto_blackhole->fetches_per_server();
#Modify fetches_per_server
$auto_blackhole->fetches_per_server(2000);
```

fetches_per_zone( )

Use this method to set or retrieve the maximum number of concurrent recursive queries for each DNS zone.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get fetches_per_zone value
my $fetches_per_zone = $auto_blackhole->fetches_per_zone();
#Modify fetches_per_zone
$auto_blackhole->fetches_per_zone(2000);
```

fps_freq( )

Use this method to set or retrieve the number of recursive queries that determines the recalculation of the timeout ratio for each DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get fps_freq value
my $fps_freq = $auto_blackhole->fps_freq();
#Modify fps_freq
$auto_blackhole->fps_freq(2000);
```

holddown( )

Use this method to set or retrieve the holddown duration for non-responsive servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get holddown value
my $holddown = $auto_blackhole->holddown();
#Modify holddown
$auto_blackhole->holddown(100);
```

holddown_threshold( )

Use this method to set or retrieve the number of consecutive timeouts before holding down a non-responsive server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get holddown_threshold value
my $holddown_threshold = $auto_blackhole->holddown_threshold();
#Modify holddown_threshold
$auto_blackhole->holddown_threshold(100);
```

holddown_timeout( )

Use this method to set or retrieve the minimum time (in seconds) that needs to be passed before a timeout occurs. Note that only these timeouts are counted towards the number of consecutive timeouts.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get holddown_timeout value
my $holddown_timeout = $auto_blackhole->holddown_timeout();
#Modify holddown_timeout
$auto_blackhole->holddown_timeout(100);
```

NAME

Infoblox::Grid::DNS::BulkHostNameTemplate - Manages the DNS bulk host name formats defined at the grid level.

DESCRIPTION

Bulk host name template defines the format based on which the host names are generated from a bulk host..

CONSTRUCTOR

```
my $bulk_host_name_template = Infoblox::Grid::DNS::BulkHostNameTemplate->new(
    template_name   => $string,    #Required
    template_format => $string     #Required
);
```

MODULE METHODS

The following functions are available to apply to the bulk host name template object.

Infoblox::Grid::DNS->bulk_host_name_templates( )

Use this function to specify a bulk host name template at the grid level in the Infoblox appliance.

Note that we can't remove or modify default bulk host name templates we can only add and modify our custom templates to the current bulk host name templates array.

Example

```
#Create a BulkHostNameTemplate object.
my $custom_template = Infoblox::Grid::DNS::BulkHostNameTemplate->new(
   template_name   => "test",
   template_format => "-#1-#2-#3-#4",
);

#Retrieve bulk host name templates array
my $bhnt = $grid_dns->bull_host_name_templates();

#Configure bulk host name template on the Infoblox grid object
push @$bhnt, $custom_template;
my $response = $grid_dns->bulk_host_name_templates($bhnt);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attributes values of a bulk host name template object.

template_name( )

Use this method to set or retrieve the name of bulk host name template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

String with the name of the bulk host name template.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get template_name
my $template_name = $bulk_host_name_template->template_name();
#Modify template_name
$template_name->template_name("new_name");
```

template_format( )

Use this method to set or retrieve the format of bulk host name template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The format of bulk host name template. It should follow certain rules (please use Administration Guide as reference).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get template_format
my $template_format = $bulk_host_name_template->template_format();
#Modify template_format
$bulk_host_name_template>template_format("-#1-#2-#3-#4");
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to a bulk host name template object such as create, modify, and remove. Also, this sample code includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
    die( "Construct session failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail() );
}
print "Session created successfully\n";

#Create a new bulk host name template object

my $my_template = Infoblox::Grid::DNS::BulkHostNameTemplate->new(
    template_name   => "My Template",
    template_format => "#4",
);
unless ($my_template) {
    die(
        "Construct bulk host name template object my_template failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail()
    );
}
print "Bulk host name template object my_template created successfully\n";

#Get the Member DNS object to add a bulk host name template object to it

my $grid_dns =
  $session->get( "object" => "Infoblox::Grid::DNS", "grid" => "Infoblox" );
```

```
unless ($grid_dns) {
    die( "Get Grid DNS failed: ",
        $session->status_code() . ":" . $session->status_detail() );
}

my $bhnt = $grid_dns->bulk_host_name_templates();

#Add new bulk host name template to Grid DNS bulk host name templates

unshift(@$bhnt, $my_template);
$grid_dns->bulk_host_name_templates($bhnt);

$session->modify($grid_dns)
  or die( "modify Grid DNS failed:",
    $session->status_code(), $session->status_detail() );
print "Modify grid DNS successful for bulk host name template object\n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::DNS::ClientSubnetDomain - a DNS client subnet domain object.

DESCRIPTION

The DNS client subnet domain represent the zone domain name that is allowed or forbidden for the EDNS client subnet (ECS) recursion.

CONSTRUCTOR

```
my $object = Infoblox::Grid::DNS::ClientSubnetDomain->new(
    'domain'     => $fqdn,            # Required
    'permission' => 'ALLOW' | 'DENY', # Optional / Default is 'ALLOW'
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions can be applied to a DNS client subnet domain object.

Infoblox::Grid::DNS->client_subnet_domains( )

Use this method to set or retrieve the list of zone domain names that are allowed or forbidden for EDNS client subnet (ECS) recursion.

Example

```
#Get client_subnet_domains value
my $value = $grid_dns->client_subnet_domains();

#Construct Infoblox::Grid::DNS::ClientSubnetDomain object
my $object = Infoblox::Grid::ClientSubnetDomain->new(
    domain     => 'domain.com',
    permission => 'DENY',
);

#Modify client_subnet_domains value
$grid_dns->client_subnet_domains([$object]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the object.

domain( )

Use this method to set or retrieve the client subnet zone domain name.

Parameter

The valid value is a Fully-Qualified Domain Name (FQDN) that represents the desired zone domain name.

Returns

The method returns the attribute value.

Example

```
#Get domain value
my $value = $object->domain();

#Modify domain value
$object->domain('test-domain.com');
```

permission( )

Use this method to set or retrieve the client subnet domain ECS permission.

Parameter

The valid values are 'ALLOW' and 'DENY'. The default value is 'ALLOW'.

Returns

The method returns the attribute value.

Example

```
#Get permission value
my $value = $object->permission();

#Modify permission value
$object->permission('DENY');
```

NAME

Infoblox::Grid::DNS::DNS64Group - DNS64 Synthesis Group object

---

DESCRIPTION

A DNS64 synthesis group is used to configure the DNS64 feature.

CONSTRUCTOR

```
 my $group = Infoblox::Grid::DNS::DNS64Group->new(
     name                  => $string,
#Required
     prefix                => $ipv6prefix,
#Required
     clients               => [ $ipv4addr | $ipv4_subnet/prefix | $ipv6addr | $ipv6_subnet/prefix ,... ] |
$nacl, #Optional / Default is an empty list
     comment               => $string,
#Optional
     disable               => "true" | "false"
#Optional / Default is "false"
     dnssec_dns64_enabled  => "true" | "false"
#Optional / Default is "false"
     exclude               => [ $ipv4addr | $ipv4_subnet/prefix | $ipv6addr | $ipv6_subnet/prefix ,... ] |
$nacl, #Optional / Default is an empty list
     extattrs              => { $string => $extattr, ... },
#Optional / Default is undefined
     extensible_attributes => { $string => $string|$num, $string => [ $string|$num, ...], ... },
#Optional / Default is undefined
     mapped                => [ $ipv4addr | $ipv4_subnet/prefix | $ipv6addr | $ipv6_subnet/prefix ,... ] |
$nacl, #Optional / Default is an empty list
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a DNS64 synthesis group object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to

take effect. See Infoblox::Session->restart() method.

Example

```
#Construct an object
my $group = Infoblox::Grid::DNS::DNS64Group->new(
    name        => "dns64group_A",
    prefix      => "64:FF9B::/96",
    );

#Submit for addition
my $response = $session->add( $group );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DNS64 synthesis group object:

 name                - Optional. Group name in string format.
 prefix              - Optional. An IPv6 prefix.
 extattrs            - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
 comment             - Optional. User-specified comment for the group.
```

Examples

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS::DNS64Group",
    name   => "dns64group_A",
    );

my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS::DNS64Group",
    extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to take effect. See Infoblox::Session->restart() method.

Example

```
#Use this method to modify the comment.
$group->comment("this is a modified comment");
#Submit modification
my $response = $session->modify( $group );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS::DNS64Group",
    name   => "dns64group_A",
     );
#Find the desired object on the retrieved list
my $desired_nsgroup= $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_nsgroup );
```

Infoblox::Session->search( )

Use this method to search for DNS64 synthesis group objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a DNS64 synthesis group object:

 name                  - Optional. Group name in string format. (regular expression)
 prefix                - Optional. An IPv6 prefix. (regular expression)
 extattrs              - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
 comment               - Optional. User-specified comment for the group. (regular expression)
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# Search for all DNS64 synthesis group objects
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::DNS::DNS64Group",
    name   => ".*",
    );

# Search for all DNS64 synthesis group objects with "Santa Clara" as the value for the "Site"
extensible attribute
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS::DNS64Group",
    extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a DNS64 synthesis group object.

comment( )

Use this method to set or retrieve the comment field of the DNS64 synthesis group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Comment of the group in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting comment
my $comment = $group->comment();
#Modifying comment
$group->comment("Some comment");
```

clients( )

Use this method to set or retrieve the clients ACL list of a DNS64 synthesis group object. This is the list of clients for which synthesized records are returned. The default is "any".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses and networks. To exclude addresses and networks, add "!" as a prefix to the IP addresses and networks. The default value is an empty list.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting clients
my $clients = $group->clients();
#Modifying clients
$group->clients(["2001::333/64", "!2001::1234", "20.0.0.0/8"]);
#Use Infoblox::Grid::NamedACL
$group->clients($nacl);
```

disable( )

Use this method to set or retrieve the disable flag of a DNS64 synthesis group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $fixed_addr->disable();
#Modify disable
$fixed_addr->disable("true");
```

dnssec_dns64_enabled( )

Use this method to set or retrieve the dnssec_dns64_enabled flag of a DNS64 synthesis group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the dnssec_dns64_enabled flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_dns64_enabled
my $dnssec_dns64_enabled = $group->dnssec_dns64_enabled();
#Modify dnssec_dns64_enabled
$group->dnssec_dns64_enabled('true');
```

exclude( )

Use this method to set or retrieve the exclude ACL list of a DNS64 synthesis group object. AAAA records which match this ACL are treated as non-existent for the purposes of synthesis. By default, the ACL is empty and no records match.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses and networks. To exclude addresses and networks, add "!" as a prefix to the IP addresses and networks. The default value is an empty list.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting exclude
my $exclude = $group->exclude();
#Modifying exclude
$group->exclude(["2001::333/64", "!2001::1234"]);
#Use Infoblox::Grid::NamedACL
$group->exclude($nacl);
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DNS64 synthesis group object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $group->extattrs();
#Modify extattrs
$group->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DNS64 synthesis group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $group->extensible_attributes();
#Modify extensible attributes
$group->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

name( )

Use this method to set or retrieve the DNS64 synthesis group name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the group in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting name
my $name = $group->name();
#Modifying name
$group->name("ns_group_2");
```

mapped( )

Use this method to set or retrieve the mapped ACL list of a DNS64 synthesis group object. The appliance generates AAAA records only for A records that match this ACL. If the ACL is empty, as it is by default, then all records will match.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses and networks. To deny addresses and networks, add "!" as a prefix to the IP addresses and networks. The default value is an empty list.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting mapped
my $mapped = $group->mapped();
#Modifying mapped
$group->mapped(["40.10.0.0/24", "!40.10.3.4]);
#Use Infoblox::Grid::NamedACL
$group->mapped($nacl);
```

prefix( )

Use this method to set or retrieve the DNS64 synthesis group prefix. The prefix is an IPv6 subnet prefix with a length of /32, /40, /48, /56, /64, or /96.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Prefix of the group in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting prefix
my $prefix = $group->prefix();
#Modifying prefix
$group->prefix("64:FF9B::/96");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as modify and remove. This sample also includes error handling for the operations.

#Preparation prior to the addition of a DNS64 synthesis group object

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox device
my $session = Infoblox::Session->new(
                                     master   => "192.168.1.2",
                                     username => "admin",
                                     password => "infoblox"
                                    );
unless ($session) {
    die("Construct session failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DNS64 synthesis group object and add it to the appliance

```
my $group = Infoblox::Grid::DNS::DNS64Group->new(
                                                 name => 'testgroup',
                                                 prefix => '64:FF9B::/96',
                                                 clients => ["2001::333/64", "!2001::1234", "20.0.0.0/8"],
                                                 comment => 'some comment',
                                                );

unless ($group) {
    die("Construct DNS64 synthesis group failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DNS64 synthesis group object created successfully\n";

my $response = $session->add( $group );
unless ($response) {
    die("Adding DNS64 synthesis group failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
```

```
}
print "Add DNS64 synthesis group success.\n" if ( $response );
```

#Add the DNS64 synthesis group object to the grid and enable it

```
my @result_array = $session->get( "object" => "Infoblox::Grid::DNS" ,  "grid" => "Infoblox" );

if ( defined @result_array  and scalar( @result_array ) > 0 ) {
    my $object = $result_array[0];
    if ( ref( $object ) eq "Infoblox::Grid::DNS" ) {
        $object->dns64_groups( [ $group ] );
        $object->enable_dns64("true");

        $response = $session->modify( $object );
        print "Add DNS64 synthesis group to grid dns properties success.\n" if ( $response );
             }

    unless ($object) {
        die("Add DNS64 synthesis group to grid dns properties failed: ",
            $session->status_code() . ":" . $session->status_detail());
    }
     }
```

#Modify the DNS64 synthesis group object

```
@result_array = $session->get( "object" => "Infoblox::Grid::DNS::DNS64Group" ,  name => "testgroup" );

if ( defined @result_array  and scalar( @result_array ) > 0 ) {
    my $object = $result_array[0];
    if ( ref( $object ) eq "Infoblox::Grid::DNS::DNS64Group" ) {

        $object->clients(["2001::333/64", "!2001::1234"]);

        $response = $session->modify( $object );
        print "Modify DNS64 synthesis group success.\n" if ( $response );
             }

    unless ($object) {
        die("Modify Group failed: ",
            $session->status_code() . ":" . $session->status_detail());
    }
     }
```

#Remove a DNS64 synthesis group object

#First let's remove it from the grid configuration

```
@result_array = $session->get( "object" => "Infoblox::Grid::DNS" ,  "grid" => "Infoblox" );

if ( defined @result_array  and scalar( @result_array ) > 0 ) {
    my $object = $result_array[0];
    if ( ref( $object ) eq "Infoblox::Grid::DNS" ) {

        $object->dns64_groups( [ ] );
        $object->enable_dns64( "false" );

        $response = $session->modify( $object );
        print "Remove DNS64 synthesis group from the grid success.\n" if ( $response );
             }

    unless ($object) {
        die("Remove DNS64 synthesis group failed: ",
            $session->status_code() . ":" . $session->status_detail());
    }
     }
```

#And now remove the group

```
@result_array = $session->get( "object" => "Infoblox::Grid::DNS::DNS64Group" ,  name => "testgroup" );

if ( defined @result_array  and scalar( @result_array ) > 0 ) {
    my $object = $result_array[0];
    if ( ref( $object ) eq "Infoblox::Grid::DNS::DNS64Group" ) {

        $response = $session->remove( $object );
        print "Remove DNS64 synthesis group success.\n" if ( $response );
```

```
            }

    unless ($object) {
        die("Remove DNS64 synthesis group failed: ",
            $session->status_code() . ":" . $session->status_detail());
    }
     }

 ####PROGRAM ENDS####
```

NAME

Infoblox::Grid::DNS::FileTransferSetting - A DNS traffic capture file transfer setting object.

DESCRIPTION

The DNS traffic capture file transfer setting object provides information and configuration for captured DNS traffic transfer to a remote server.

CONSTRUCTOR

```
my $transfer_setting = Infoblox::Grid::DNS::FileTransferSetting->new(
    type      => 'NONE' | 'FTP' | 'SCP', # Required
    directory => $string,                # Optional / default is undefined
    host      => $string,                # Optional / default is undefined
    username  => $string,                # Optional / default is undefined
    password  => $string,                # Optional / default is undefined
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions are available to be applied to a DNS traffic capture file transfer setting object.

Infoblox::Grid::DNS->file_transfer_setting( )

Use this method to set or retrieve the DNS capture file transfer settings. See Infoblox::Grid::DNS->file_transfer_setting() for parameters and return values.

Example

```
#Get override_enable_excluded_domain_names value
my $override_enable_excluded_domain_names = $object->override_enable_excluded_domain_names();

#Modify override_enable_excluded_domain_names value
$object->override_enable_excluded_domain_names("true");
```

Infoblox::Grid::Member::DNS->file_transfer_setting( )

Use this method to set or retrieve the DNS capture file transfer settings. See Infoblox::Grid::Member::DNS->file_transfer_setting() for parameters and return values.

Example

```
#Get override_enable_excluded_domain_names value
my $override_enable_excluded_domain_names = $object->override_enable_excluded_domain_names();
```

```
#Modify override_enable_excluded_domain_names value
$object->override_enable_excluded_domain_names("true");
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DNS traffic capture file transfer setting object.

directory( )

Use this method to set or retrieve the directory to save the captured DNS queries and responses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired path in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get directory value
my $directory = $object->directory();

#Modify directory value
$object->directory('/path/to/dir');
```

host( )

Use this method to set or retrieve the hostname for the DNS capture transfer destination server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is Fully-Qualified Domain Name (FQDN) of the DNS capture transfer destination server.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get host value
my $host = $object->host();

#Modify host value
$object->host('transfer.com');
```

password( )

Use this method to set the password to access the destination server directory. This is a write-only attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired password in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Modify password value
$object->password('pass');
```

type( )

Use this method to set or retrieve the transfer protocol used to capture DNS queries and responses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value are 'FTP', 'SCP' and 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get type value
my $type = $object->type();

#Modify type value
$object->type('SCP');
```

username( )

Use this method to set or retrieve the username to access the destination server directory.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired username in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get username value
my $username = $object->username();

#Modify username value
$object->username('admin');
```

Infoblox::Grid::DNS::FixedRRSetOrderFQDN - A fixed RRset order FQDN object.

- NAME
- DESCRIPTION
- CONSTRUCTOR
- SESSION METHODS
- METHODS
  - fqdn( )
  - record_type( )
- AUTHOR
- SEE ALSO
- COPYRIGHT

NAME

Infoblox::Grid::DNS::FixedRRSetOrderFQDN - A fixed RRset order FQDN object.

DESCRIPTION

A fixed RRset order FQDN contains information about the fixed RRset configuration items.

By default, when a client queries a domain name, the DNS caching appliance returns the A and AAAA records of the domain name in the cyclic order. However, this default behavior can be overridden if you have enabled and configured (at the Grid level) fixed RRset order for hosts that have multiple addresses. When you override the default behavior and preserve the fixed RRset order for cached DNS responses, the DNS caching appliance returns A and AAAA records associated with domain names in the order they were received from an upstream server. You can preserve the RRset order for the cached DNS responses and specify the fixed RRset order for A, AAAA, or both A and AAAA records at the Grid level and override at the member and DNS view levels.

Note that configuring fixed RRset order for specific FQDNs might significantly affect the performance of the DNS caching appliance.

CONSTRUCTOR

```
my $rrset_order = Infoblox::Grid::DNS::FixedRRSetOrderFQDN->new(
    fqdn        => $string,               #Required
    record_type => 'A' | 'AAAA' | 'BOTH', #Optional / Default is 'A'
);
```

SESSION METHODS

The object does not support any session methods. It's used for fixed RRset order configuration for Infoblox::Grid::DNS, Infoblox::Grid::Member::DNS, Infoblox::DNS::View objects.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

fqdn( )

Use this method to set or retrieve the FQDN of the fixed RRset configuration item.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string containing desired FQDN.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get fqdn value
my $fqdn = $order_fqdn->fqdn();
#Modify fqdn
$order_fqdn->fqdn('domain.com');
```

record_type( )

Use this method to set or retrieve the returned record type for the specified FQDN in the fixed RRset configuration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'A', 'AAAA' and 'BOTH'. The default value is 'A'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get record_type value
my $record_type = $order_fqdn->record_type();
#Modify record_type
$order_fqdn->record_type('AAAA');
```

NAME

Infoblox::Grid::DNS::Nsgroup - Creates a name server group.

DESCRIPTION

A name server group is a collection of one and more primary DNS servers and one or more secondary DNS servers. Grouping a commonly used set of primary and secondary DNS servers together simplifies zone creation, allowing you to specify a single name server group instead of specifying multiple name servers individually.

CONSTRUCTOR

```
 my $nsg1 = Infoblox::Grid::DNS::Nsgroup->new(
     name         => $string,                                                          #Required
     comment      => $string,                                                          #Optional
     extattrs              => { $string => $extattr, ... },                            #Optional
/ Default is undefined
     extensible_attributes => { $string => $string|$num, $string => [ $string|$num, ...], ... },  #Optional
/ Default is undefined
     is_multimaster       => "true" | "false",                                        #Optional
/ Default is "false"
     multiple_primaries   => [$Member1, ...] | [$Nameserver1, ...] | [$MSServer1, ...],  #Optional
/ Default is undefined
     secondaries          => [$Member1, $Member2, $Nameserver1, $Nameserver2, ...]     #Optional
/ List of Infoblox::DNS::Member object(s) and/or Infoblox::DNS::Nameserver object(s).
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to an Nsgroup object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Creating Member objects.
my $member1 = Infoblox::DNS::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
    stealth  => "false"
    );
```

```
my $member2 = Infoblox::DNS::Member->new(
    name     => "member2.test.com",
    ipv4addr => "2.2.2.2",
    stealth  => "false"
    );

#Creating a nameserver object.
my $nameserver1 = Infoblox::DNS::Nameserver->new(
    name     => "ns1.test.extra",
    ipv4addr => "4.4.4.4",
    stealth  => "false",
    TSIGname => "tsig_name",
    TSIGkey  => "ZX1jVJl7C58GT/sc7Q3ucA=="
    );

#Creating a nameserver object.
my $nameserver2 = Infoblox::DNS::Nameserver->new(
    name     => "ns2.test.extra",
    ipv4addr => "5.5.5.5",
    stealth  => "false",
    TSIGname => "tsig_name2",
    TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
    );

#Creating a nameserver object.
my $nameserver3 = Infoblox::DNS::Nameserver->new(
    name     => "ns3.test.extra",
    ipv6addr => "12ab::34a",
    stealth  => "false",
    TSIGname => "tsig_name2",
    TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
    );

#Construct an object
my $nsg1 = Infoblox::Grid::DNS::Nsgroup->new(
    name        => "ns_group_A",
    multiple_primaries => [$member1],
    secondaries => [$member2, $nameserver1, $nameserver2, $nameserver3]
    );

#Submit for addition
my $response = $session->add( $nsg1 );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Nsgroup object:

 name - Required. A name server group name in string format.
 extattrs      - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Examples

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS::Nsgroup",
    name   => "ns_group_A",
    );

my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS::Nsgroup",
    extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use this method to modify the comment.
$nsg1->comment("this is a modified comment");
#Submit modification
my $response = $session->modify( $nsg1 );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS::Nsgroup",
    name   => "ns_group_A",
     );
#Find the desired object from the retrieved list.
my $desired_nsgroup= $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_nsgroup );
```

Infoblox::Session->search( )

Use this method to search for Nsgroup objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for an Nsgroup object:

 name - Required. A host name in string format (regular expression).
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# Search for all Nsgroup objects
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::DNS::Nsgroup",
    name   => ".*",
    );

# search for all Nsgroup objects with "Santa Clara" as the value for the "Site" extensible attribute
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS::Nsgroup",
    extensible_attributes => { 'Site' => 'Santa Clara' });
```

MODULE METHODS

This section describes all the methods that you can appy to an Nsgroup object.

Infoblox::Grid::DNS->nsgroups( )

Use this function to specify a name server group at the grid level on the Infoblox appliance. See Infoblox::Grid::DNS->nsgroups() for parameters and return values.

Example

```
#Creating Member objects.

my $member1 = Infoblox::DNS::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
    stealth  => "false"
    );

my $member2 = Infoblox::DNS::Member->new(
    name     => "member2.test.com",
    ipv4addr => "2.2.2.2",
    stealth  => "false"
    );

#Creating a nameserver object.
my $nameserver1 = Infoblox::DNS::Nameserver->new(
    name     => "ns1.test.extra",
    ipv4addr => "4.4.4.4",
```

```
    stealth  => "false",
    TSIGname => "tsig_name",
    TSIGkey  => "ZX1jVJl7C58GT/sc7Q3ucA=="
    );

#Creating a nameserver object.
my $nameserver2 = Infoblox::DNS::Nameserver->new(
    name     => "ns2.test.extra",
    ipv4addr => "5.5.5.5",
    stealth  => "false",
    TSIGname => "tsig_name2",
    TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
    );

#Creating a nameserver object.
my $nameserver3 = Infoblox::DNS::Nameserver->new(
    name     => "ns3.test.extra",
    ipv6addr => "12ab::34a",
    stealth  => "false",
    TSIGname => "tsig_name2",
    TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
    );

my $nsg1 = Infoblox::Grid::DNS::Nsgroup->new(
    name        => "ns_group_A",
    multiple_primaries => [$member1],
    secondaries => [$member2, $nameserver1, $nameserver2,$nameserver3]
    );

my @result_array = $session->get( "object" => "Infoblox::Grid::DNS" ,  "grid" => "Infoblox" );

 my $dns = $result_array[0];
 $dns->nsgroups([$nsg1]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an Nsgroup object

name( )

Use this method to set or retrieve the name server group, providing a meaningful reference for the set of servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the nameserver group in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
 #Getting name
  my $name = $nsg1->name();
  #Modifying name
  $nsg1->name("ns_group_2");
```

comment( )

Use this method to set or retrieve the comment field of the Nsgroup object. You can enter additional information about the NS group in this field.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Comment of the nameserver group in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting comment
my $comment = $nsg1->comment();
#Modifying comment
$nsg1->comment("Some comment");
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with an Nsgroup object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $nsg1->extensible_attributes();
#Modify extensible attributes
$nsg1->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

is_multimaster( )

Use this method to set or retrieve the is_multimaster flag.

Parameter

Specify "true" to set the is_multimaster flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $attr = $nsg1->is_multimaster();
# Modify the attribute value
$nsg1->is_multimaster('true');
```

multiple_primaries( )

Use this method to set or retrieve Grid primary servers or external primary servers of the name server group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DNS::Member objects for Grid primary servers or Infoblox::DNS::Nameserver objects for external primary servers.

To set two and more Infoblox::DNS::Member objects you should set the is_multimaster flag to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#For grid primary:

my $member1 = Infoblox::DNS::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
```

```
    stealth  => "true"
);

$nsg1->multiple_primaries([$member1]);

#For external primary:

my $nameserver1 = Infoblox::DNS::Nameserver->new(
    name     => "ns1.domain.extra",
    ipv4addr => "5.5.5.5",
    stealth  => "false",
    TSIGname => "tsig_name",
    TSIGkey  => "ZX1jVJl7C58GT/sc7Q3ucA=="
);

my $nameserver2 = Infoblox::DNS::Nameserver->new(
    name     => "ns2.domain.extra",
    ipv4addr => "6.6.6.6",
    stealth  => "false",
    TSIGname => "tsig_name2",
    TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
);

#Creating a nameserver object.
my $nameserver3 = Infoblox::DNS::Nameserver->new(
    name     => "ns3.test.extra",
    ipv6addr => "12ab::34a",
    stealth  => "false",
    TSIGname => "tsig_name2",
    TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
    );

$nsg1->multiple_primaries([$nameserver1, $nameserver2,$nameserver3]);
```

secondaries( )

Use this method to set or retrieve the grid secondary server or external secondary servers of the nameserver group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DNS::Member objects for grid secondary servers and Infoblox::DNS::Nameserver objects for external secondary servers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
my $member2 = Infoblox::DNS::Member->new(
    name     => "member2.domain.com",
    ipv4addr => "2.2.2.2",
    stealth  => "false"
);

my $nameserver1 = Infoblox::DNS::Nameserver->new(
    name     => "ns1.domain.extra",
    ipv4addr => "4.4.4.4",
    stealth  => "false",
    TSIGname => "tsig_name",
    TSIGkey  => "ZX1jVJl7C58GT/sc7Q3ucA=="
);

my $nameserver2 = Infoblox::DNS::Nameserver->new(
    name     => "ns2.domain.extra",
    ipv4addr => "5.5.5.5",
    stealth  => "false",
    TSIGname => "tsig_name2",
    TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
);

#Creating a nameserver object.
my $nameserver3 = Infoblox::DNS::Nameserver->new(
```

```
            name     => "ns3.test.extra",
            ipv6addr => "12ab::34a",
            stealth  => "false",
            TSIGname => "tsig_name2",
            TSIGkey  => "qwqwqwqwqwqwqwqwqwqA=="
            );

      $nsg1->secondaries([$member2, $nameserver1, $nameserver2,$nameserver3]);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as modify and remove. This sample also includes error handling for the operations.

#Preparation prior to an Nsgroup object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox device
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an Nsgroup object

```
#Creating a member object.
my $member1 = Infoblox::DNS::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
    stealth  => "false"
);

#Creating a nsgroup object.
my $nsg1 = Infoblox::Grid::DNS::Nsgroup->new(
    name    => "ns_group_1",
    multiple_primaries => [$member1]
);

my $nsg1_A = Infoblox::Grid::DNS::Nsgroup->new(
    name    => "ns_group_A",
    multiple_primaries => [$member1]
);

unless ($nsg1) {
   die("Construct Nsgroup failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Nsgroup object created successfully\n";
```

#Get and add the Nsgroup object

```
my @result_array = $session->get( "object" => "Infoblox::Grid::DNS" ,  "grid" => "Infoblox" );

if( defined @result_array  and scalar( @result_array ) > 0 )

NAME

Infoblox::Grid::DNS::Nsgroup::DelegationMember - A delegation nameservers group.

DESCRIPTION

When you configure a name server group, you can now create a set of external name servers as a delegation name server group and assign it to delegated zones. Specifying a single delegation name server group instead of configuring multiple name servers individually for delegated zones can significantly reduce configuration efforts.

CONSTRUCTOR

```
 my $object = Infoblox::Grid::DNS::Nsgroup::DelegationMember->new(
     name                  => $string,
#Required
     delegation_servers    => [$nameserver1, $nameserver1, ...],
#Required
     comment               => $string,
#Optional / Default is undefined
     extattrs              => { $string => $extattr, ... },
#Optional / Default is undefined
     extensible_attributes => {$string => $string | $num, $string => [ $string | $num, ... ], ... }
#Optional / Default is undefined
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a delegation members group object.

Infoblox::Session->add( )

Use this method to add the object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $object = Infoblox::Grid::DNS::Nsgroup::DelegationMember->new(
    name               => 'dlggroup',
    delegation_servers => [$nameserver1, $nameserver2],
);

#Submit for addition
my $response = $session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attributes to get a specific delegation member group object:

 comment               - Optional. The delegation member group comment in a string format.
 name                  - Optional. The delegation member group name in a string format.
 extattrs              - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::Nsgroup::DelegationMember',
    name   => 'dlggroup',
);
```

Infoblox::Session->modify( )

Use this method to modify the object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify comment value
$object->comment('this is a modified comment');

#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove the object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP range object, and then submit this object for removal.

Example

```
#Get the objects
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::Nsgroup::DelegationMember',
    name   => 'dlggroup',
);

#Find the desired object from the retrieved list
my $desired_object = $retrieved_objs[0];

#Submit for removal
my $response = $session->remove($desired_object);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for the delegation member group object:

 comment               - Optional. The delegation member group comment in a string format (regexp).
 name                  - Optional. The delegation member group name in a string format (regexp).
 extattrs              - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for objects
my @retrieved_objs = $session->search(
    object  => 'Infoblox::Grid::DNS::Nsgroup::DelegationMember',
    name    => '^dlg.*',
    comment => '.*comment',
);
```

```
# search for objects defining 'Santa Clara' for 'Site' extensible attribute
my @retrieved_objs = $session->search(
    object               => 'Infoblox::Grid::DNS::Nsgroup::DelegationMember',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a delegation member group.

comment( )

Use this method to set or retrieve the delegation member group comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $comment = $object->comment();

#Modify comment value
$object->comment('dlg comment');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a delegation member group object.

Parameter

Valid value is a hash reference that contains the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs value
my $extattrs = $object->extattrs();

#Modify extattrs value
$object->extattrs({'Site' => $extattr1, 'Administrator' => $extattr2});
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a delegation member group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes value
my $extensible_attributes = $object->extensible_attributes();
```

```
#Modify extensible attributes
$object->extensible_attributes({'Site' => 'Santa Clara', 'Administrator' => ['Peter', 'Tom']});
```

delegation_servers( )

Use this method to set or retrieve the list of delegation servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::DNS::Nameserver objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get delegation_servers value
my $delegation_servers = $object->delegation_servers();

#Modify delegation_servers value

#Create nameserver object
my $nameserver = Infoblox::DNS::Nameserver->new(
    name     => 'ns1.domain1.extra',
    ipv4addr => '5.5.5.5',
);

#Set delegation_servers value
$object->delegation_servers([$nameserver]);
```

name( )

Use this method to set or retrieve the delegation member group name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();

#Modify name value
$object->name('dlgg1');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as modify and remove. This sample also includes error handling for the operations.

#Preparation prior to an Delegation Member Nsgroup object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

my ($session, $result);

#Create a session to the Infoblox device
$session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
```

```
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an Delegation Member Nsgroup object

```
#Creating an external nameserver
my $nameserver = Infoblox::DNS::Nameserver->new(
    name      => "ns1.domain0.external",
    ipv4addr => "5.5.5.5",
);

#Creating a delegation nsgroup object.
my $dlg_nsg1 = Infoblox::Grid::DNS::Nsgroup::DelegationMember->new(
    name               => "dlg_group_1",
    delegation_servers => [$nameserver],
);

unless ($dlg_nsg1) {
   die("Construct Delegation Member Nsgroup failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "Delegation Member Nsgroup object constructed successfully\n";
```

#Add the Nsgroup object

```
$result = $session->add($dlg_nsg1);

unless ($result) {
    die("Add Delegation Member Nsgroup to session failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Delegation Member Nsgroup object created successfully\n";
```

#Search and Modify the Nsgroup object

```
my @result_array = $session->search(
    object => "Infoblox::Grid::DNS::Nsgroup::DelegationMember",
    name   => "dlg_.*",
);

my $object = $result_array[0];

unless ($object) {
   die("Search for Delegation Member Nsgroup failed: ",
       $session->status_code() . ":" . $session->status_detail());
}

$result = $object->comment("delegation member");

unless ($result) {
    die("Modify Delegation Member Nsgroup failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}

$result = $session->modify($object);

unless ($result) {
    die("Submit modification to the session failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Delegation Member Nsgroup object modified successfully\n";
```

#Remove a Nsgroup object

```
my @result_array = $session->get(
    object => "Infoblox::Grid::DNS::Nsgroup::DelegationMember",
    name   => "dlg_group_1",
);

my $object = $result_array[0];
```

```
unless ($object) {
   die("Get Delegation Member Nsgroup failed: ",
       $session->status_code() . ":" . $session->status_detail());
}

$result = $session->remove($object);

unless ($result) {
    die("Remove Nsgroup failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Delegation Member Nsgroup object removed successfully\n";

NAME

Infoblox::Grid::DNS::Nsgroup::ForwardingMember - A forwarding member group.

DESCRIPTION

The forwarding member group provides forwarding servers configuration for forward zones.

CONSTRUCTOR

```
 my $object = Infoblox::Grid::DNS::Nsgroup::ForwardingMember->new(
     name                  => $string,
#Required
     forwarding_servers    => [$dnsmember1, $dnsmember2, ...],
#Required
     comment               => $string,
#Optional / Default is undefined
     extattrs              => { $string => $extattr, ... },
#Optional / Default is undefined
     extensible_attributes => {$string => $string | $num, $string => [ $string | $num, ... ], ... }
#Optional / Default is undefined
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a forwarding members group object.

Infoblox::Session->add( )

Use this method to add the object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $object = Infoblox::Grid::DNS::Nsgroup::ForwardingMember->new(
    name             => 'fwdgroup',
    forwarding_servers => [$dnsmember1, $dnsmember2],
);

#Submit for addition
my $response = $session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attributes to get a specific forwarding member group object:

 comment               - Optional. The forwarding member group comment in a string format.
 name                  - Optional. The forwarding member group name in a string format.
 extattrs              - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::Nsgroup::ForwardingMember',
    name   => 'fwdgroup',
);

# search for objects defining 'Santa Clara' for 'Site' extensible attribute
my @retrieved_objs = $session->search(
    object               => 'Infoblox::Grid::DNS::Nsgroup::ForwardingMember',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

Infoblox::Session->modify( )

Use this method to modify the object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify comment value
$object->comment('this is a modified comment');

#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove the object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP range object, and then submit this object for removal.

Example

```
#Get the objects
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::Nsgroup::ForwardingMember',
    name   => 'fwdgroup',
);

#Find the desired object from the retrieved list
my $desired_object = $retrieved_objs[0];

#Submit for removal
my $response = $session->remove($desired_object);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for the forwarding member group object:

 comment               - Optional. The forwarding member group comment in a string format (regexp).
 name                  - Optional. The forwarding member group name in a string format (regexp).
 extattrs              - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# search for objects
my @retrieved_objs = $session->search(
    object  => 'Infoblox::Grid::DNS::Nsgroup::ForwardingMember',
```

```
    name    => '^fwd.*',
    comment => '.*comment',
);

# search for objects defining 'Santa Clara' for 'Site' extensible attribute
my @retrieved_objs = $session->search(
    object               => 'Infoblox::Grid::DNS::Nsgroup::ForwardingMember',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a forwarding member group.

comment( )

Use this method to set or retrieve the forwarding member group comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $comment = $object->comment();

#Modify comment value
$object->comment('fwd comment');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a forwarding member group object.

Parameter

Valid value is a hash reference that contains the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs value
my $extattrs = $object->extattrs();

#Modify extattrs value
$object->extattrs({'Site' => $extattr1, 'Administrator' => $extattr2});
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a forwarding member group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes value
my $extensible_attributes = $object->extensible_attributes();
#Modify extensible attributes
$object->extensible_attributes({'Site' => 'Santa Clara', 'Administrator' => ['Peter', 'Tom']});
```

forwarding_servers( )

Use this method to set or retrieve the list of forwarding servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::DNS::Member objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get forwarding_servers value
my $forwarding_servers = $object->forwarding_servers();

#Modify forwarding_servers value

#Create nameserver object
my $nameserver = Infoblox::DNS::Nameserver->new(
    name     => 'ns1.domain1.extra',
    ipv4addr => '5.5.5.5',
);

#Create dns member object
my $dnsmember = Infoblox::DNS::Member->new(
    ipv4addr   => '1.1.1.1',
    forward_to => [$nameserver],
);

#Set forwarding_servers value
$object->forwarding_servers([$dnsmember]);
```

name( )

Use this method to set or retrieve the forwarding member group name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();

#Modify name value
$object->name('fwdg1');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as modify and remove. This sample also includes error handling for the operations.

#Preparation prior to an Forwarding Member Nsgroup object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
```

```
use Infoblox;

my ($session, $result);

#Create a session to the Infoblox device
$session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an Forwarding Member Nsgroup object

```
#Creating an external nameserver
my $nameserver = Infoblox::DNS::Nameserver->new(
    name     => "ns1.domain0.external",
    ipv4addr => "5.5.5.5",
);

#Creating a forwarding member object.
my $fwd_member = Infoblox::DNS::Member->new(
    name       => "infoblox.localdomain",
    ipv4addr   => "192.168.1.2",
    forward_to =>  [$nameserver],
);

#Creating a forwarding nsgroup object.
my $fwd_nsg1 = Infoblox::Grid::DNS::Nsgroup::ForwardingMember->new(
    name               => "fwd_group_1",
    forwarding_servers => [$fwd_member],
);

unless ($fwd_nsg1) {
   die("Construct Forwarding Member Nsgroup failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "Forwarding Member Nsgroup object constructed successfully\n";
```

#Add the Nsgroup object

```
$result = $session->add($fwd_nsg1);

unless ($result) {
    die("Add Forwarding Member Nsgroup to session failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Forwarding Member Nsgroup object created successfully\n";
```

#Search and Modify the Nsgroup object

```
my @result_array = $session->search(
    object => "Infoblox::Grid::DNS::Nsgroup::ForwardingMember",
    name   => "fwd_.*",
);

my $object = $result_array[0];

unless ($object) {
   die("Search for Forwarding Member Nsgroup failed: ",
       $session->status_code() . ":" . $session->status_detail());
}

$result = $object->comment("forwarding member");

unless ($result) {
    die("Modify Forwarding Member Nsgroup failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}

$result = $session->modify($object);
```

```
unless ($result) {
    die("Submit modification to the session failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Forwarding Member Nsgroup object modified successfully\n";
```

#Remove a Nsgroup object

```
my @result_array = $session->get(
    object => "Infoblox::Grid::DNS::Nsgroup::ForwardingMember",
    name   => "fwd_group_1",
);

my $object = $result_array[0];

unless ($object) {
   die("Get Forwarding Member Nsgroup failed: ",
       $session->status_code() . ":" . $session->status_detail());
}

$result = $session->remove($object);

unless ($result) {
    die("Remove Nsgroup failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Forwarding Member Nsgroup object removed successfully\n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::DNS::Nsgroup::ForwardStubServer - A forward/stub external nameserver group.

DESCRIPTION

The forward/stub external nameserver group provides forward/stub external servers configuration for forward zones.

CONSTRUCTOR

```
 my $object = Infoblox::Grid::DNS::Nsgroup::ForwardStubServer->new(
     name                  => $string,                                                  #
Required
     external_servers      => [$ns1, $ns2, ...],                                        #
Required
     comment               => $string,                                                  #
Optional / Default is undefined
     extattrs              => { $string => $extattr, ... },                             #
Optional / Default is undefined
     extensible_attributes => {$string => $string | $num, $string => [ $string | $num, ... ], ... } #
Optional / Default is undefined
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a forward/stub external nameservers group object.

Infoblox::Session->add( )

Use this method to add the object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $object = Infoblox::Grid::DNS::Nsgroup::ForwardStubServer->new(
    name             => 'extsrvgroup',
    external_servers => [$ns1, $ns2],
);

#Submit for addition
my $response = $session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return

values.

Key Reference

```
 Apply the following attributes to get a specific forward/stub external nameserver group object:

  comment               - Optional. The forward/stub external nameserver group comment in a string
format.
  name                  - Optional. The forward/stub external nameserver group name in a string
format.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::Nsgroup::ForwardStubServer',
    name   => 'extsrvgroup',
);

my @retrieved_objs = $session->get(
    object               => 'Infoblox::Grid::DNS::Nsgroup::ForwardStubServer',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

Infoblox::Session->modify( )

Use this method to modify the object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify comment value
$object->comment('this is a modified comment');

#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove the object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP range object, and then submit this object for removal.

Example

```
#Get the objects
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::Nsgroup::ForwardStubServer',
    name   => 'extsrvgroup',
);

#Find the desired object from the retrieved list
my $desired_object = $retrieved_objs[0];

#Submit for removal
my $response = $session->remove($desired_object);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
 Apply the following attributes to search for the forward/stub external nameserver group object:

  comment               - Optional. The forward/stub external nameserver group comment in a string
format (regexp).
  name                  - Optional. The forward/stub external nameserver group name in a string
format (regexp).
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for objects
my @retrieved_objs = $session->search(
    object  => 'Infoblox::Grid::DNS::Nsgroup::ForwardStubServer',
    name    => '^ext.*',
    comment => '.*comment',
);

# search for objects defining 'Santa Clara' for 'Site' extensible attribute
my @retrieved_objs = $session->search(
    object               => 'Infoblox::Grid::DNS::Nsgroup::ForwardStubServer',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a forward/stub external nameserver group.

comment( )

Use this method to set or retrieve the forward/stub external nameserver group comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $comment = $object->comment();

#Modify comment value
$object->comment('ext comment');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a forward/stub external nameserver group object.

Parameter

Valid value is a hash reference that contains the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs value
my $extattrs = $object->extattrs();

#Modify extattrs value
$object->extattrs({'Site' => $extattr1, 'Administrator' => $extattr2});
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a forward/stub external nameserver group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes value
my $extensible_attributes = $object->extensible_attributes();
#Modify extensible attributes
$object->extensible_attributes({'Site' => 'Santa Clara', 'Administrator' => ['Peter', 'Tom']});
```

external_servers( )

Use this method to set or retrieve the list of forward/stub external nameservers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::DNS::Nameserver objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get external_servers value
my $external_servers = $object->external_servers();

#Modify external_servers value

#Create nameserver object
my $nameserver = Infoblox::DNS::Nameserver->new(
    name      => 'ns1.domain1.extra',
    ipv4addr => '5.5.5.5',
);

#Set external_servers value
$object->external_servers([$nameserver]);
```

name( )

Use this method to set or retrieve the forward/stub external nameserver group name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();

#Modify name value
$object->name('extsrvgroup');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as modify and remove. This sample also includes error handling for the operations.

#Preparation prior to an Forward Stub Server Nsgroup object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;
```

```
my ($session, $result);

#Create a session to the Infoblox device
$session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an Forward Stub Server Nsgroup object

```
#Creating an external nameserver
my $nameserver = Infoblox::DNS::Nameserver->new(
    name     => "ns1.domain0.external",
    ipv4addr => "5.5.5.5",
);

#Creating a forwarding nsgroup object.
my $fwd_stub_nsg1 = Infoblox::Grid::DNS::Nsgroup::ForwardStubServer->new(
    name             => "fwd_stub_group_1",
    external_servers => [$nameserver],
);

unless ($fwd_stub_nsg1) {
   die("Construct Forward Stub Server Nsgroup failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "Forward Stub Server Nsgroup object constructed successfully\n";
```

#Add the Nsgroup object

```
$result = $session->add($fwd_stub_nsg1);

unless ($result) {
    die("Add Forward Stub Server Nsgroup to session failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Forward Stub Server Nsgroup object created successfully\n";
```

#Search and Modify the Nsgroup object

```
my @result_array = $session->search(
    object => "Infoblox::Grid::DNS::Nsgroup::ForwardStubServer",
    name   => "fwd_stub_.*",
);

my $object = $result_array[0];

unless ($object) {
   die("Search for Forward Stub Server Nsgroup failed: ",
       $session->status_code() . ":" . $session->status_detail());
}

$result = $object->comment("forwarding member");

unless ($result) {
    die("Modify Forward Stub Server Nsgroup failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}

$result = $session->modify($object);

unless ($result) {
    die("Submit modification to the session failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Forward Stub Server Nsgroup object modified successfully\n";
```

#Remove a Nsgroup object

```
my @result_array = $session->get(
    object => "Infoblox::Grid::DNS::Nsgroup::ForwardStubServer",
    name   => "fwd_stub_group_1",
);

my $object = $result_array[0];

unless ($object) {
   die("Get Forward Stub Server Nsgroup failed: ",
       $session->status_code() . ":" . $session->status_detail());
}

$result = $session->remove($object);

unless ($result) {
    die("Remove Nsgroup failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Forward Stub Server Nsgroup object removed successfully\n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::DNS::Nsgroup::StubMember - A stub member group.

DESCRIPTION

The stub member group provides stub servers configuration for stub zones.

CONSTRUCTOR

```
 my $object = Infoblox::Grid::DNS::Nsgroup::StubMember->new(
     name                  => $string,
#Required
     stub_members          => [$grid_member1, $grid_member2, ...],
#Required
     comment               => $string,
#Optional / Default is undefined
     extattrs              => { $string => $extattr, ... },
#Optional / Default is undefined
     extensible_attributes => {$string => $string | $num, $string => [ $string | $num, ... ], ... }
#Optional / Default is undefined
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a stub members group object.

Infoblox::Session->add( )

Use this method to add the object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $object = Infoblox::Grid::DNS::Nsgroup::StubMember->new(
    name         => 'stubgroup',
    stub_members => ['member1.com', 'member2.com'],
);

#Submit for addition
my $response = $session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attributes to get a specific stub member group object:

 comment               - Optional. The stub member group comment in a string format.
 name                  - Optional. The stub member group name in a string format.
 extattrs              - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::Nsgroup::StubMember',
    name   => 'stubgroup',
);

my @retrieved_objs = $session->get(
    object               => 'Infoblox::Grid::DNS::Nsgroup::StubMember',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

Infoblox::Session->modify( )

Use this method to modify the object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify comment value
$object->comment('this is a modified comment');

#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove the object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP range object, and then submit this object for removal.

Example

```
#Get the objects
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::Nsgroup::StubMember',
    name   => 'stubgroup',
);

#Find the desired object from the retrieved list
my $desired_object = $retrieved_objs[0];

#Submit for removal
my $response = $session->remove($desired_object);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attributes to search for the stub member group object:

 comment               - Optional. The stub member group comment in a string format (regexp).
 name                  - Optional. The stub member group name in a string format (regexp).
 extattrs              - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for objects
my @retrieved_objs = $session->search(
    object  => 'Infoblox::Grid::DNS::Nsgroup::StubMember',
    name    => '^stub.*',
```

```
    comment => '.*comment',
);

# search for objects defining 'Santa Clara' for 'Site' extensible attribute
my @retrieved_objs = $session->search(
    object               => 'Infoblox::Grid::DNS::Nsgroup::StubMember',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a stub member group.

comment( )

Use this method to set or retrieve the stub member group comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $comment = $object->comment();

#Modify comment value
$object->comment('stub comment');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a stub member group object.

Parameter

Valid value is a hash reference that contains the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs value
my $extattrs = $object->extattrs();

#Modify extattrs value
$object->extattrs({'Site' => $extattr1, 'Administrator' => $extattr2});
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a stub member group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes value
my $extensible_attributes = $object->extensible_attributes();
#Modify extensible attributes
$object->extensible_attributes({'Site' => 'Santa Clara', 'Administrator' => ['Peter', 'Tom']});
```

stub_members( )

Use this method to set or retrieve the list of stub members.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Grid Member host names in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get stub_members value
my $stub_members = $object->stub_members();

#Modify stub_members value

#Set stub_members value
$object->stub_members(['member1.com', 'member2.com']);
```

name( )

Use this method to set or retrieve the stub member group name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();

#Modify name value
$object->name('stubg1');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as modify and remove. This sample also includes error handling for the operations.

#Preparation prior to an Stub Member Nsgroup object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

my ($session, $result);

#Create a session to the Infoblox device
$session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
```

```
print "Session created successfully\n";
```

#Create an Stub Member Nsgroup object

```
#Creating a forwarding nsgroup object.
my $stub_nsg1 = Infoblox::Grid::DNS::Nsgroup::StubMember->new(
    name         => "stub_group_1",
    stub_members => ["infoblox.localdomain"],
);

unless ($stub_nsg1) {
   die("Construct Stub Member Nsgroup failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "Stub Member Nsgroup object constructed successfully\n";
```

#Add the Nsgroup object

```
$result = $session->add($stub_nsg1);

unless ($result) {
    die("Add Stub Member Nsgroup to session failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Stub Member Nsgroup object created successfully\n";
```

#Search and Modify the Nsgroup object

```
my @result_array = $session->search(
    object => "Infoblox::Grid::DNS::Nsgroup::StubMember",
    name   => "stub_.*",
);

my $object = $result_array[0];

unless ($object) {
   die("Search for Stub Member Nsgroup failed: ",
       $session->status_code() . ":" . $session->status_detail());
}

$result = $object->comment("stub member");

unless ($result) {
    die("Modify Stub Member Nsgroup failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}

$result = $session->modify($object);

unless ($result) {
    die("Submit modification to the session failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Stub Member Nsgroup object modified successfully\n";
```

#Remove a Nsgroup object

```
my @result_array = $session->get(
    object => "Infoblox::Grid::DNS::Nsgroup::StubMember",
    name   => "stub_group_1",
);

my $object = $result_array[0];

unless ($object) {
   die("Get Stub Member Nsgroup failed: ",
       $session->status_code() . ":" . $session->status_detail());
}

$result = $session->remove($object);

unless ($result) {
    die("Remove Nsgroup failed: ",
        $session->status_code() . ":" . $session->status_detail());
```

```
}

print "Stub Member Nsgroup object removed successfully\n";

NAME

Infoblox::Grid::DNS::ResponseRateLimiting - a DNS Response Rate Limiting object.

DESCRIPTION

The DNS Response Rate Limiting object provides information about DNS response rate limiting configuration.

CONSTRUCTOR

```
my $response_rate_limiting = Infoblox::Grid::DNS::ResponseRateLimiting->new(
        enable_rrl           => 'true' | 'false', # Optional
        log_only             => 'true' | 'false', # Optional
        responses_per_second => $uint,            # Optional
        window               => $uint,            # Optional
        slip                 => $uint,            # Optional
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions can be applied to a DNS Response Rate Limiting object.

Infoblox::Grid::DNS->response_rate_limiting( )

+Use this method to set or retrieve DNS response rate limiting settings. See Infoblox::Grid::DNS->response_rate_limiting() for parameters and return values.

Example

```
#Get response_rate_limiting value
my $response_rate_limiting = $grid_dns->response_rate_limiting();
#Modify bind_check_response_rate_limiting
$grid_dns->response_rate_limiting($response_rate_limiting);
```

Infoblox::Grid::Member::DNS->response_rate_limiting( )

Use this method to set or retrieve DNS response rate limiting settings on the member. See Infoblox::Grid::Member::DNS->response_rate_limiting() for parameters and return values.

Example

```
#Get response_rate_limiting value
my $response_rate_limiting = $member_dns->response_rate_limiting();
#Modify response_rate_limiting
$member_dns->response_rate_limiting($response_rate_limiting);
```

Infoblox::DNS::View->response_rate_limiting( )

Use this method to set or retrieve DNS response rate limiting settings for the DNS view. See Infoblox::DNS::View->response_rate_limiting() for parameters and return values.

Example

```
#Get response_rate_limiting value
my $response_rate_limiting = $dns_view->response_rate_limiting();
#Modify response_rate_limiting
$dns_view->response_rate_limiting($response_rate_limiting);
```

METHODS

---

enable_rrl( )

Use this method to enabel or disable response rate limiting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable response rate limiting or 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_rrl value
my $enable_rrl = $response_rate_limiting->enable_rrl();
#Modify enable_rrl
$response_rate_limiting->enable_rrl('true');
```

---

log_only( )

Use this method to enable or disable logging for response rate limiting without dropping any requests.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable logging for response rate limiting without dropping any requests or 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get log_only value
my $log_only = $response_rate_limiting->log_only();
#Modify log_only
$response_rate_limiting->log_only('true');
```

---

responses_per_second( )

Use this method to set or retrieve the number of responses per client per second.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get responses_per_second value
my $responses_per_second = $response_rate_limiting->responses_per_second();
#Modify responses_per_second
$response_rate_limiting->responses_per_second(50);
```

---

slip( )

Use this method to set or retrieve the response rate limiting slip.

Note that if a slip does not equal 0, instead of dropping the request, a truncated response is sent to each n-th rate-limited UDP request.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get slip value
my $slip = $response_rate_limiting->slip();
#Modify slip
$response_rate_limiting->slip(50);
```

---

window( )

Use this method to set or retrieve the time interval in seconds over which responses are tracked.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get window value
my $window = $response_rate_limiting->window();
#Modify window
$response_rate_limiting->window(10);
```

NAME

Infoblox::Grid::DNS::ScavengingSetting - A DNS scavenging settings object.

DESCRIPTION

The DNS scavenging settings object provides information about DNS records scavenging configuration such as the conditions under which records can be reclaimed and periodicity of the scavening operations.

CONSTRUCTOR

```
my $reclamation_setting = Infoblox::Grid::DNS::ScavengingSetting->new(
    ea_expression_list          => [$ea_expr1, $ea_expr2, ...], # Optional / Default is undefined
    enable_auto_reclamation     => 'true' | 'false',            # Optional / Default is 'false'
    enable_recurrent_scavenging => 'true' | 'false',            # Optional / Default is 'false'
    enable_rr_last_queried      => 'true' | 'false',            # Optional / Default is 'false'
    enable_scavenging           => 'true' | 'false',            # Optional / Default is 'false'
    enable_zone_last_queried    => 'true' | 'false',            # Optional / Default is 'false'
    expression_list             => [$expr1, $expr2, ...],       # Optional / Default is undefined
    reclaim_associated_records  => 'true' | 'false',            # Optional / Default is 'false'
    scavenging_schedule         => $sched_setting,              # Optional / Default is undefined
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

Infoblox::Grid::DNS->scavenging_settings( )

Use this method to set or retrieve the Grid-level scavenging settings. See Infoblox::Grid::DNS->scavenging_settings() for parameters and return values.

Example

```
#Get scavenging_settings value
my $scavenging_settings = $object->scavenging_settings();

#Modify scavenging_settings value
$object->scavenging_settings($scavenging_settings);
```

Infoblox::DNS::View->scavenging_settings( )

Use this method to set or retrieve the DNS view-level scavenging settings. See Infoblox::DNS::View->scavenging_settings() for parameters and return values.

Example

```
#Get scavenging_settings value
my $scavenging_settings = $object->scavenging_settings();

#Modify scavenging_settings value
$object->scavenging_settings($scavenging_settings);
```

Infoblox::DNS::Zone->scavenging_settings( )

Use this method to set or retrieve the DNS zone-level scavenging settings. See Infoblox::DNS::Zone->scavenging_settings() for parameters and return values.

Example

```
#Get scavenging_settings value
my $scavenging_settings = $object->scavenging_settings();

#Modify scavenging_settings value
$object->scavenging_settings($scavenging_settings);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a DNS scavenging settings object.

ea_expression_list( )

Use this method to set or retrieve the extensible attributes expression list.

The particular record is treated as reclaimable if the extensible attribute expression condition evaluates to 'true' and scavenging is not manually disabled on the given record. Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::EAExpressionOp objects.

The following is a table of allowed expression operand parameters:

op1_type	op1	op2_type	op2	op
FIELD	Infoblox::Grid::ExtensibleAttributeDef	STRING	$value	EQ, NOT_EQ
	Infoblox::Grid::ExtensibleAttributeDef	undef	undef	EXISTS, NOT_EXISTS
LIST	undef	undef	undef	AND, OR, ENDLIST

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ea_expression_list value
my $ea_expression_list = $object->ea_expression_list();

#Construct expression (Site == LA OR Site == CA)

my $ead = Infoblox::Grid::ExtensibleAttributeDef->new(
    name => 'Site',
);

my $start_list = Infoblox::Grid::EAExpressionOp->new(
    op1_type => 'LIST',
    op       => 'OR',
);
```

```
my $ea_op1 = Infoblox::Grid::EAExpressionOp->new(
    op1_type => 'FIELD',
    op1      => $ead,
    op2_type => 'STRING',
    op2      => 'LA',
    op       => 'EQ',
);

my $ea_op2 = Infoblox::Grid::EAExpressionOp->new(
    op1_type => 'FIELD',
    op1      => $ead,
    op2_type => 'STRING',
    op2      => 'CA',
    op       => 'EQ',
);

my $end_list = Infoblox::Grid::EAExpressionOp->new(
    op1_type => 'LIST',
    op       => 'ENDLIST',
);

#Modify ea_expression_list value
$object->ea_expression_list([$start_list, $ea_op1, $ea_op2, $end_list]);
```

enable_scavenging( )

Use this method to set or retrieve the flag that indicates whether the resource record scavenging is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the resource record reclamation or 'false' to disable it. The default value is 'false'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_scavenging value
my $enable_scavenging = $object->enable_scavenging();

#Modify enable_scavenging value
$object->enable_scavenging('true');
```

enable_recurrent_scavenging( )

Use this method to set or retrieve the flag that indicates whether the recurrent resource record scavenging is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the recurrent resource record scavenging or 'false' to disable it. The default value is 'false'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_recurrent_scavenging value
my $enable_recurrent_scavenging = $object->enable_recurrent_scavenging();

#Modify enable_recurrent_scavenging value
$object->enable_recurrent_scavenging('true');
```

enable_rr_last_queried( )

Use this method to set or retrieve the flag that indicates whether the resource record last queried monitoring in affected zones is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the resource record last queried monitoring or 'false' to disable it. The default value is 'false'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_rr_last_queried value
my $enable_rr_last_queried = $object->enable_rr_last_queried();

#Modify enable_rr_last_queried value
$object->enable_rr_last_queried('true');
```

enable_zone_last_queried( )

Use this method to set or retrieve the flag that indicates whether the last queried monitoring for affected zones is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the last queried monitoring for affected zones or 'false' to disable it. The default value is 'false'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_zone_last_queried value
my $enable_zone_last_queried = $object->enable_zone_last_queried();

#Modify enable_zone_last_queried value
$object->enable_zone_last_queried('true');
```

enable_auto_reclamation( )

Use this method to set or retrieve the flag that indicates whether the automatic resource record reclamation is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the automatic resource record reclamation or 'false' to disable it. The default value is 'false'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_auto_reclamation value
my $enable_auto_reclamation = $object->enable_auto_reclamation();

#Modify enable_auto_reclamation value
$object->enable_auto_reclamation('true');
```

reclaim_associated_records( )

Use this method to set or retrieve the flag that indicates whether the associated resource record reclamation is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the associated resource record reclamation or 'false' to disable it. The default value is 'false'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

G #Get reclaim_associated_records value my $reclaim_associated_records = $object->reclaim_associated_records();

```
#Modify reclaim_associated_records value
$object->reclaim_associated_records('true');
```

expression_list( )

Use this method to set or retrieve the expression list.

The particular record is treated as reclaimable if expression condition evaluates to 'true' for given record if reclamation hasn't been manually disabled on a given resource record.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::ExpressionOp objects.

The following is a table of allowed expression operand parameters:

```
  +----------+-------------------------------------------------------------+----------+-------------------
------------------------------+----------------------------------+
  | op1_type | op1                                                         | op2_type | op2
|  op                          |
  +----------+-------------------------------------------------------------+----------+-------------------
------------------------------+----------------------------------+
  |          | rtype    - the resource record type                         | STRING   | A, AAAA, CNAME,
DNAME, MX, NAPTR, PTR, SRV, TXT | EQ, NOT_EQ                     |
  |          | ctime    - the resource record creation time                | STRING   | $uint
| GT (in days)                 |
  |          | qtime    - the resource record last queried time            | STRING   | $uint
| GT (in days)                 |
  | FIELD    | stime    - the resource record last seen time               | STRING   | $uint
| GT (in days)                 |
  |          | rcreator - the resource record creator                      | STRING   | STATIC, DYNAMIC
| EQ                           |
  |          | assocr   - the resource record associated record            | undef    | undef
| EXISTS, NOT_EXISTS           |
  +----------+-------------------------------------------------------------+----------+-------------------
------------------------------+----------------------------------+
  | LIST     | undef                                                       | undef    | undef
| AND, OR, ENDLIST             |
  +----------+-------------------------------------------------------------+----------+-------------------
------------------------------+----------------------------------+
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get expression_list value
my $expression_list = $object->expression_list();

#Construct expression (rcreator == DYNAMIC AND ctime > 10)

my $start_list = Infoblox::Grid::ExpressionOp->new(
    op1_type => 'LIST',
    op       => 'AND',
);

my $op1 = Infoblox::Grid::ExpressionOp->new(
    op1_type => 'FIELD',
    op1      => 'rcreator',
    op2_type => 'STRING',
    op2      => 'DYNAMIC',
    op       => 'EQ',
);

my $op2 = Infoblox::Grid::ExpressionOp->new(
    op1_type => 'FIELD',
    op1      => 'ctime',
    op2_type => 'STRING',
    op2      => '10',
```

```
    op       => 'GT',
);

my $end_list = Infoblox::Grid::ExpressionOp->new(
    op1_type => 'LIST',
    op       => 'ENDLIST',
);

#Modify expression_list value
$object->expression_list([$start_list, $op1, $op2, $end_list]);
```

scavenging_schedule( )

Use this method to set or retrieve the scavenging schedule settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ScheduleSetting object.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get scavenging_schedule value
my $scavenging_schedule = $object->scavenging_schedule();

#Modify scavenging_schedule value
$object->scavenging_schedule($schedule);
```

NAME

Infoblox::Grid::DNS::ScavengingTask - A DNS scavenging task object.

DESCRIPTION

The DNS scavenging task object provides information on scavenging process state. This is a read-only object.

The object is created as a result of Infoblox::Session->run_scavenging() function call and cannot be added or removed manually.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a DNS scavenging task object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:
    associated_object - Optional. The DNS object associated with scavenging process.
    action            - Optional. The scavenging action.
    status            - Optional. The scavenging status.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::DNS::ScavengingTask',
    action => 'ANALYZE',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:
    associated_object - Optional. The DNS object associated with scavenging process.
    action            - Optional. The scavenging action.
    status            - Optional. The scavenging status.
```

Example

```
my @retrieved_objs = $session->search(
    object => 'Infoblox::Grid::DNS::ScavengingTask',
    action => 'ANALYZE',
);
```

METHODS

This section describes all the methods that you can use to retrieve the attribute values of a DNS scavenging task object.

action( )

Use this method to retrieve the scavenging action. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'ANALYZE', 'RECLAIM', 'ANALYZE_RECLAIM' and 'RESET'.

Example

```
#Get action value
my $action = $object->action();
```

associated_object( )

Use this method to retrieve the object associated with the scavenging task. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are Infoblox::Grid::DNS, Infoblox::DNS::View and Infoblox::DNS::Zone.

Example

```
#Get associated_object value
my $associated_object = $object->associated_object();
```

end_time( )

Use this method to retrieve the end time for the scavenging task. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value, the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get end_time value
my $end_time = $object->end_time();
```

processed_records( )

Use this method to retrieve the number of resource records being processed during the scavenging process. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get processed_records value
```

```
my $processed_records = $object->processed_records();
```

reclaimable_records( )

Use this method to retrieve the number of scavenged resource records during the scavenging process. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get reclaimable_records value
my $reclaimable_records = $object->reclaimable_records();
```

reclaimed_records( )

Use this method to retrieve the number of reclaimed during the scavenging process resource records. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get reclaimed_records value
my $reclaimed_records = $object->reclaimed_records();
```

start_time( )

Use this method to retrieve the start time for the scavenging process. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value, the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get start_time value
my $start_time = $object->start_time();
```

status( )

Use this method to retrieve the scavenging process status. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'CREATED', 'RUNNING'. 'COMPLETED' and 'ERROR'.

Example

```
#Get status value
my $status = $object->status();
```

NAME

Infoblox::Grid::EAExpressionOp - A extensible attribute expression operand object.

DESCRIPTION

The extensible attribute expression operand object is used to build an extensible attribute expression lists. The allowed values for the expression operand object depend on the object they appear to be a part of.

CONSTRUCTOR

```
 my $expression = Infoblox::Grid::EAExpressionOp->new(
     op       => 'AND'| 'ENDLIST'| 'EQ'| 'EXISTS'| 'NOT_EQ'| 'NOT_EXISTS'| 'OR', # Required
     op1      => $ead,                                                          # Optional / Default is
undefined
     op2      => $string,                                                       # Optional / Default is
undefined
     op1_type => 'FIELD' | 'LIST' | 'STRING',                                   # Optional / Default is
undefined
     op2_type => 'FIELD' | 'LIST' | 'STRING',                                   # Optional / Default is
undefined
 );
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

Infoblox::Grid::DNS::ReclamationSetting->ea_expression_list( )

Use this method to set or retrieve the ea_expression list. See Infoblox::Grid::DNS::ReclamationSetting->ea_expression_list() for parameters and return values.

Example

```
#Get ea_expression_list value
my $ea_expression_list = $object->ea_expression_list();

#Modify ea_expression_list value
$object->ea_expression_list([$start_list, $op1, $op2, $end_list]);
```

METHODS

op( )

Use this method to set or retrieve the operation name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'AND', 'ENDLIST', 'EQ', 'EXISTS', 'NOT_EQ', 'NOT_EXISTS' and 'OR'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op value
my $op = $object->op();

#Modify op value
$object->op('AND');
```

op1( )

Use this method to set or retrieve the first operand value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ExtensibleAttributeDef object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op1 value
my $op1 = $object->op1();

#Modify op1 value
$object->op1($ead);
```

op1_type( )

Use this method to set or retrieve the first operand type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'FIELD', 'LIST' and 'STRING'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op1_type value
my $op1_type = $object->op1_type();

#Modify op1_type value
$object->op1_type('LIST');
```

op2( )

Use this method to set or retrieve the second operand value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains the second operand value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op2 value
my $op2 = $object->op2();

#Modify op2 value
$object->op2('OP2_VAL');
```

op2_type( )

Use this method to set or retrieve the second operand type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'FIELD', 'LIST' and 'STRING'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op2_type value
my $op2_type = $object->op2_type();

#Modify op2_type value
$object->op2_type('STRING');
```

NAME

Infoblox::Grid::ExpressionOp - An expression operand object.

DESCRIPTION

The expression operand object is used to build expression lists. The allowed values for the expression operand object depend on the object they appear to be a part of.

CONSTRUCTOR

```
 my $expression = Infoblox::Grid::ExpressionOp->new(
     op       => 'AND'| 'OR'| 'GT'| 'GE'| 'LT'| 'LE'| 'EQ'| 'NOT_EQ'| 'ENDLIST'| 'EXISTS'| 'MATCH_IP'|
'MATCH_RANGE'| 'MATCH_CIDR', # Required
     op1      => $string,
# Optional / Default is undefined
     op2      => $string,
# Optional / Default is undefined
     op1_type => 'FIELD' | 'LIST' | 'STRING',
# Optional / Default is undefined
     op2_type => 'FIELD' | 'LIST' | 'STRING',
# Optional / Default is undefined
 );
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

Infoblox::Grid::DNS::ReclamationSetting->expression_list( )

Use this method to set or retrieve the expression list. See Infoblox::Grid::DNS::ReclamationSetting->expression_list() for parameters and return values.

Example

```
#Get expression_list value
my $expression_list = $object->expression_list();

#Modify expression_list value
$object->expression_list([$start_list, $op1, $op2, $end_list]);
```

METHODS

op( )

Use this method to set or retrieve the operation name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'AND', 'ENDLIST', 'GT', 'LT', 'LE', 'GE', 'MATCH_IP', 'MATCH_RANGE', 'MATCH_CIDR', 'EQ', 'EXISTS', 'NOT_EQ', 'NOT_EXISTS' and 'OR'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op value
my $op = $object->op();

#Modify op value
$object->op('LE');
```

op1( )

Use this method to set or retrieve the first operand value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains the first operand value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op1 value
my $op1 = $object->op1();

#Modify op1 value
$object->op1('OP1_VAL');
```

op1_type( )

Use this method to set or retrieve the first operand type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'FIELD', 'LIST' and 'STRING'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op1_type value
my $op1_type = $object->op1_type();

#Modify op1_type value
$object->op1_type('LIST');
```

op2( )

Use this method to set or retrieve the second operand value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains the second operand value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op2 value
my $op2 = $object->op2();

#Modify op2 value
$object->op2('OP2_VAL');
```

op2_type( )

Use this method to set or retrieve the second operand type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'FIELD', 'LIST' and 'STRING'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get op2_type value
my $op2_type = $object->op2_type();

#Modify op2_type value
$object->op2_type('STRING');
```

NAME

Infoblox::Grid::Extattr - an extensible attribute representation for an attribute.

DESCRIPTION

An object that provides an extensible attribute representation for an attribute.

CONSTRUCTOR

```
my $extattr = Infoblox::Grid::Extattr->new(
   value                => $scalar | [$scalar1, $scalar2, ...],      # required
   inheritance_operation => 'DELETE' | 'INHERIT' | 'OVERRIDE',       # optional
   descendants_action    => $descendants,                            # optional
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the extensible attribute representation for an attribute.

descendants_action( )

Use this method to set the actions for extensible attributes that exist on descendants. This attribute is write-only and cannot be retrieved.

Parameter

Valid value is an Infoblox::Grid::ExtensibleAttributeDef::Descendants object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify attribute value
$extattr->descendants_action($descendants);
```

inheritance_operation( )

Use this method to set the operation that will be performed on an extensible attribute. This attribute is write-only and cannot be retrieved.

Parameter

Valid value is 'DELETE', 'INHERIT' or 'OVERRIDE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify attribute value
$extattr->inheritance_operation('INHERIT');
```

inheritance_source( )

Use this method to retrieve the object from which the extensible attribute was inherited. This attribute is read-only and cannot be set

This object is considered a 'partial' object. See Infoblox::Session->fill_partial_object() for more information on how it can be converted to a 'full' API object.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get attribute value
my $value = $extattr->inheritance_source();
```

value( )

Use this method to set or retrieve the value of the extensible attribute representation for an attribute.

Parameter

For email, URL, and string types, the value is a string with a maximum of 256 characters.

For a list, the value is a reference to an array of strings with a maximum of 64 characters.

For an integer, the value is an integer from -2147483648 through 2147483647.

For a date, the value is the number of seconds that have elapsed since January 1st, 1970 UTC or a string in YYYY-MM-DD format. Any date entered will be converted to an epoch time corresponding to that day at 11:01am UTC.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $extattr->value();
#Modify attribute value
$extattr->value('www.infoblox.com');
```

NAME

Infoblox::Grid::ExtensibleAttributeDef - Extensible Attribute Definition object.

DESCRIPTION

The Extensible Attribute Definition object is used to create or modify the definition of an extensible attribute. After the definition is created, the attribute can be defined on other Infoblox objects.

Searching Extensible Attributes

When searching for integer, string and date extensible attributes, the following constructs are supported, in addition to specifying the actual desired value.

String Searching

The string search can be modified by specifying the string in the following format:

```
 stringattr => { value => $wantedstring, ... options ... }
```

the following options are supported:

```
 case_insensitive => "true" | "false" # Optional. If "true", the string search will be case insensitive.
The default is "false".
```

Following is an example of a string search:

```
 @result = $session->search(object => 'Infoblox::DNS::Record::A',
                            extensible_attributes => { stringattr => { value => "some string",
case_insensitive => "true"});
```

Integer Searching

Integer searches support the following where X and Y are integers:

'> X' or '< X' - Matches if the extensible attribute value is GREATER or LESS than X respectively.
'>= X' or '<= X' - Matches if the extensible attribute value is GREATER THAN OR EQUALS or is LESS THAN OR EQUALS X respectively.
'!= X' or '/= X' - Matches if the extensible attribute value DOES NOT EQUAL X.
'>=< X,Y' - Matches if the extensible attribute value is GREATER THAN OR EQUALS X AND is LESS THAN OR EQUALS Y.

Following are examples of integer searches:

```
@result = $session->search(object => 'Infoblox::DNS::Record::A',
                           extensible_attributes => { integerattr => '<= 5'});

@result = $session->search(object => 'Infoblox::DNS::Record::A',
                           extensible_attributes => { integerattr => '!= 5'});

@result = $session->search(object => 'Infoblox::DNS::Record::A',
                           extensible_attributes => { integerattr => '>=< 5,10'});
```

Date Searching

Valid values for dates when searching are:

The number of seconds that have elapsed since January 1st, 1970 UTC.
A string matching 'YYYY-MM-DD'.
'today', 'yesterday', 'tomorrow'.
'this week', 'this month'.

Date searches support the following where X and Y are dates:

'> X' or '< X' - Matches if the extensible attribute value is GREATER or LESS than X respectively.
'>= X' or '<= X' - Matches if the extensible attribute value is GREATER THAN OR EQUALS or is LESS THAN OR EQUALS X respectively.
'>=< X,Y' - Matches if the extensible attribute value is GREATER THAN OR EQUALS X AND is LESS THAN OR EQUALS Y. This is supported only for epoch or YYYY-MM-DD strings.
'- n' or '+ n' where n is an integer - Matches if the extensible attribute value is within the past or next n days respectively, excluding today.

Following are examples of date searches:

```
@result = $session->search(object => 'Infoblox::DNS::Record::A',
                           extensible_attributes => { dateattr => '<= yesterday'});

@result = $session->search(object => 'Infoblox::DNS::Record::A',
                           extensible_attributes => { dateattr => 'this week'});

@result = $session->search(object => 'Infoblox::DNS::Record::A',
                           extensible_attributes => { dateattr => '>=< 2010-10-20,2010-11-01'});

@result = $session->search(object => 'Infoblox::DNS::Record::A',
                           extensible_attributes => { dateattr => '- 3'});
```

Extensible Attribute Values

The valid value for an extensible attribute is a hash reference containing the names of extensible attributes and their associated values.

The names must be those of existing Infoblox::Grid::ExtensibleAttributeDef objects in the database.

For email, URL, and string types, the value is a string with a maximum of 256 characters.

For a list, the value is a string with a maximum of 64 characters.

For an integer, the value is an integer from -2147483648 through 2147483647.

For a date, the value is the number of seconds that have elapsed since January 1st, 1970 UTC or a string of the format YYYY-MM-DD. Any date entered will be converted to an epoch time corresponding to that day at 11:01am UTC.

The default value for the member is undefined.

CONSTRUCTOR

```
my $ext_attr_def = Infoblox::Grid::ExtensibleAttributeDef->new(
```

```
    name                => $string,                                                    #Required
    type                => "string" | "integer" | "email" | "date" | "list" | "url",   #Optional
/ Default is "string"
    comment             => $string,                                                    #Optional
/ Default is undefined
    audit_log           => "true" | "false",                                           #Optional
/ Default is "false"
    inheritable         => "true" | "false",                                           #Optional
/ Default is "false"
    multiple            => "true" | "false",                                           #Optional
/ Default is "false"
    cloud_api           => "true" | "false",                                           #Optional
/ Default is "false"
    mgm_private         => "true" | "false",                                           #Optional
/ Default is "false"
    grid_master         => "true" | "false",                                           #Optional
/ Default is "false"
    default_value       => $string | $num,                                             #Optional
/ Default is undefined
    list_values         => [$Value1, $Value2, ...],                                    #Optional
/ Default is undefined (Mandatory if Extensible Attributes of type='list' is defined; optional otherwise)
    min                 => $num,                                                       #Optional
/ Default is undefined
    max                 => $num,                                                       #Optional
/ Default is undefined
    allowed_object_types=> [$string, $string, ...]                                     #Optional
/ Default is undefined
    user_input          => 'recommended' | 'required' | 'optional',                    #Optional
/ Default is 'optional'
    descendants_action  => $descendants,                                               #Optional
/ Default is undefined
 );
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to an Extensible Attribute Definition object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
# Construct an Extensible Attribute Definition object
my $ext_attr_def = Infoblox::Grid::ExtensibleAttributeDef->new(
    name                => "test_ext_attr",
    comment             => "test extensible attribute",
    type                => "integer"
);
# Submit for addition
my $response = $session->add( $ext_attr_def );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Extensible Attribute Definition object:

 name      - Required. Extensible Attribute Definition name in string format.
 namespace - Optional. Extensible Attribute Definition namespace.
```

Example

```
my @retrieved_objs = $session->get(
    object     => "Infoblox::Grid::ExtensibleAttributeDef",
    name       => "test_ext_attr" );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment.
$ext_attr_def->comment("This is a modified comment");
# Submit modification
```

```
my $response = $session->modify( $ext_attr_def );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, use `get()` or `search()` to retrieve the specific object first, and then submit this object for removal.

Example

```
# Get the Extensible Attribute Definition object matching the given name
my @retrieved_objs = $session->get(
    object     => "Infoblox::Grid::ExtensibleAttributeDef",
    name       => "test_ext_attr" );
# Find the desired object from the retrieved list.
my $ext_attr_def = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $ext_attr_def );
```

Infoblox::Session->search( )

Use this method to search for Extensible Attribute Definition objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific Extensible Attribute Definition object:

 name      - Optional. Extensible Attribute Definition name (regular expression).
 comment   - Optional. Extensible Attribute Definition comment (regular expression).
 namespace - Optional. Extensible Attribute Definition namespace.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all Extensible Attribute Definition objects starting with "test"
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::ExtensibleAttributeDef",
    name   => "test.*" );
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of an Extensible Attribute Definition object.

allowed_object_types( )

Use this method to set or retrieve the object types on which the extensible attribute can be defined.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Parameter is an array reference that contains the list of object types on which the extensible attribute can be defined. The following object types are supported here:

```
Infoblox::Grid::Member
Infoblox::Grid::Admin::User
Infoblox::Grid::Admin::Role
Infoblox::DHCP::FailOver
Infoblox::DHCP::Filter::Fingerprint
Infoblox::DHCP::Filter::MAC
Infoblox::DHCP::Filter::NAC
Infoblox::DHCP::Filter::Option
Infoblox::DHCP::Filter::RelayAgent
Infoblox::DHCP::Fingerprint
Infoblox::DHCP::FixedAddr
Infoblox::DHCP::FixedAddrTemplate
Infoblox::DHCP::IPv6FixedAddr
Infoblox::DHCP::IPv6FixedAddrTemplate
Infoblox::DHCP::IPv6Network
Infoblox::DHCP::IPv6Network
Infoblox::DHCP::IPv6NetworkContainer
Infoblox::DHCP::IPv6NetworkContainer
Infoblox::DHCP::IPv6NetworkTemplate
Infoblox::DHCP::IPv6Range
Infoblox::DHCP::IPv6RangeTemplate
Infoblox::DHCP::IPv6SharedNetwork
Infoblox::DHCP::MAC
Infoblox::DHCP::MSSuperscope
Infoblox::DHCP::Network
```

```
Infoblox::DHCP::NetworkContainer
Infoblox::DHCP::NetworkTemplate
Infoblox::DHCP::Range
Infoblox::DHCP::RangeTemplate
Infoblox::DHCP::RoamingHost
Infoblox::DHCP::SharedNetwork
Infoblox::DHCP::View
Infoblox::DNS::BulkHost
Infoblox::DNS::Host
Infoblox::DNS::RPZRecord::A
Infoblox::DNS::RPZRecord::AAAA
Infoblox::DNS::RPZRecord::AAAAIpAddress
Infoblox::DNS::RPZRecord::AIpAddress
Infoblox::DNS::RPZRecord::CNAME
Infoblox::DNS::RPZRecord::CNAME::ClientIpAddress
Infoblox::DNS::RPZRecord::CNAME::ClientIpAddressDN

```

If the parameter is undefined, the extensible attribute can be defined on all object types. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get allowed object types
my $ref_allowed_object_types = $ext_attr_def->allowed_object_types();
# Modify allowed object types
$ext_attr_def->allowed_object_types(['Infoblox::DHCP::Range', 'Infoblox::DHCP::RangeTemplate']);
```

audit_log( )

Use this method to set or retrieve the "audit_log" flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the audit_log flag or "false" to deactivate/unset it. When the flag is set the extensible attribute name and value assigned to an object are logged in the audit log when a change occurs on the object. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get audit_log flag
my $audit_log = $ext_attr_def->audit_log();
# Modify audit_log flag
$ext_attr_def->audit_log("true");
```

comment( )

Use this method to set or retrieve the comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Comment in string format with a maximum of 256 characters. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $ext_attr_def->comment();
#Modify comment
$ext_attr_def->comment("This is the modified comment for extensible attribute definition");
```

default_value( )

Use this method to set or retrieve the value used to pre-populate the attribute value in the GUI.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Default value used to pre-populate the attribute value in the GUI. For email, URL, and string types, the value is a string with a maximum of 256 characters. For a list, the value is a string with a maximum of 64 characters. For an integer, the value is an integer from -2147483648 through 2147483647. For a date, the value is the number of seconds that have elapsed since January 1st, 1970 UTC. The default value is undefined.

Note that, for a date, the time value is automatically modified to 11:01:00 before insertion, so you may not get the same value that you've inserted upon retrieval. e.g. 1000000 (1970-01-12T13:46:40Z) will be returned as 990060 (1970-01-12T11:01:00Z).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get default value of an extensible attribute of type string
my $ext_attr_def = $ext_attr_def->default_value();
# Modify default value
$ext_attr_def->default_value("Router");
```

descendants_action( )

Use this method to set the actions for extensible attributes that exist on descendants. This attribute is write-only and cannot be retrieved.

Parameter

Valid value is an Infoblox::Grid::ExtensibleAttributeDef::Descendants object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify attribute value
$ext_attr_def->descendants_action($descendants);
```

inheritable( )

Use this method to set or retrieve the "inheritable" flag.

Parameter

Specify "true" to set the inheritable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get inheritable flag
my $inheritable = $ext_attr_def->inheritable();
# Modify inheritable flag
$ext_attr_def->inheritable("true");
```

list_values( )

Use this method to set or retrieve the list of values that can be defined for the list type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Parameter is an array reference that contains Infoblox::Grid::ExtensibleAttributeDef::ListValue values associated with an extensible attribute object defined as the "list" type. This parameter is not used for other types. The default value for this field is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get list of values
my $ref_list_values = $ext_attr_def->list_values();

# Add a new value to the list
my $ref_list_values = $ext_attr_def->list_values();
push @$ref_list_values, Infoblox::Grid::ExtensibleAttributeDef::ListValue->new(value => 'Santa
Clara');
$ext_attr_def->list_values($ref_list_values);

# Rename a value in the list
my $ref_list_values = $ext_attr_def->list_values();
foreach my $value (@$ref_list_values)
{
   if ($value->value() eq 'San Francisco')
   {
       $value->value('Los Angeles');
   }
}
$ext_attr_def->list_values($ref_list_values);
```

max( )

Use this method to set or retrieve the maximal length of string for string type or maximal value for integer type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For a string, the value is an integer from 1 through 256. For an integer, the value is an integer from -2147483648 through

2147483647. This parameter is not used for other types. Using the Infoblox::Session->modify() function you can only define a value greater than the current one. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get max
my $ext_attr_def = $ext_attr_def->max();
# Modify max
$ext_attr_def->max(23);
```

min( )

Use this method to set or retrieve the minimal length of string for string type or minimal value for integer type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For a string, the value is an integer from 1 through 256. For an integer, the value is an integer from -2147483648 through 2147483647. This parameter is not used for other types. Using the Infoblox::Session->modify() function you can only define a value lesser than the current one. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get min
my $ext_attr_def = $ext_attr_def->min();
# Modify min
$ext_attr_def->min(3);
```

multiple( )

Use this method to set or retrieve the "multiple" flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the multiple flag or "false" to deactivate/unset it. When the flag is set multiple values can be assigned to an extensible attribute. Using the Infoblox::Session->modify() function you can change this flag from "false" to "true". The reverse operation is not allowed. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get multiple flag
my $audit_log = $ext_attr_def->multiple();
# Modify multiple flag
$ext_attr_def->multiple("true");
```

cloud_api( )

Use this method to set or retrieve the "cloud_api" flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the cloud_api flag or "false" to deactivate or unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get cloud_api flag
my $cloud_api = $ext_attr_def->cloud_api();
# Modify cloud_api flag
$ext_attr_def->cloud_api("true");
```

grid_master( )

Use this method to set or retrieve the "grid_master" flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the grid_master flag or "false" to deactivate or unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get grid_master flag
my $grid_master = $ext_attr_def->grid_master();
# Modify grid_master flag
$ext_attr_def->grid_master("true");
```

mgm_private( )

Use this method to set or retrieve the "mgm_private" flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the mgm_private flag or "false" to deactivate or unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get mgm_private flag
my $mgm_private = $ext_attr_def->mgm_private();
# Modify mgm_private flag
$ext_attr_def->mgm_private("true");
```

name( )

Use this method to set or retrieve the name of an extensible attribute definition.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the extensible attribute with a maximum of 128 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get name
my $name = $ext_attr_def->name();
# Modify name
$ext_attr_def->name("Class");
```

namespace( )

Use this method to retrieve the extensible attribute definition namespace. This is a read-only attribute.

Specific extensible attribute definitions with 'RIPE' namespace will be added only when support for RIR/SWIP is enabled at the Grid level for the first time. See Infoblox::Grid->enable_rir_swip() method.

Parameter

None

Returns

The method returns the attribute value that can be 'default', 'MSADSITES', 'RIPE' or 'CLOUD'.

Example

```
# Get namespace
$namespace = $ext_attr_def->namespace();
```

type( )

Use this method to set or retrieve the type of an extensible attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Parameter is a string. The default value for this field is "string". Currenty the supported object types are 'string', 'integer', 'email', 'date', 'list' and 'url'. Modification of the type using the Infoblox::Session->modify() function is not allowed.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get type
my $type = $ext_attr_def->type();
```

user_input( )

Use this method to set or retrieve the flag that indicates whether the extensible attribute value is required, recommended or optional.

Parameter

Valid values are 'recommended', 'required' or 'optional'. The default value is 'optional'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get user_input
my $user_input = $ext_attr_def->user_input();
#Modify user_input
$ext_attr_def->user_input('required');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, get, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to an Extensible Attribute Definition object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
                                        #appliance host ip
```

```
                master   => "192.168.1.2",
                username => "admin",        #appliance user login
                password => "infoblox"      #appliance password
                );

unless (($session) {
        die("Construct session failed: ",
                Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an Extensible Attribute Definition object

```
my $ext_attr_def = Infoblox::Grid::ExtensibleAttributeDef->new(
    name                => "test_extensible_atttribute",
    comment             => "test extensibleatttribute",
    type                => "integer",
    min                 => -50,
    max                 => 50,
);

unless (($ext_attr_def) {
        die("Construct extensible attribute definition object failed: ",
                Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Extensible Attribute Definition object created successfully\n";

#Add this object to the Infoblox appliance through a session
$session->add($ext_attr_def)
        or die("Add Extensible Attribute Definition object failed: ",
                        $session->status_code() . ":" . $session->status_detail());
print "Extensible Attribute Definition object added to server successfully\n";
```

#Get and modify an Extensible Attribute Definition object

```
#Get the object from Infoblox appliance through a session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::ExtensibleAttributeDef",
    name   => "test_extensible_atttribute"
);
my $object = $retrieved_objs[0];

unless (($object) {
        die("Get Extensible Attribute Definition object failed: ",
                $session->status_code() . ":" . $session->status_detail());
}
print "Get Extensible Attribute Definition object found at least 1 matching entry\n";

#Modify the object
$object->comment("this is a new comment");
$object->min(-100);
$object->max(100);

#Apply the changes.
$session->modify($object)
        or die("Modify Extensible Attribute definition object failed: ",
                $session->status_code() . ":" . $session->status_detail());
print "Extensible Attribute definition object modified successfully \n";

#Accessor methods
print "name: " . $object->name() . "\n";
print "comment: " . $object->comment() . "\n";
print "min: " . $object->min() . "\n";
print "max: " . $object->max() . "\n";
```

#Remove an Extensible Attribute Definition object

```
#Get the object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::ExtensibleAttributeDef",
    name   => "test_extensible_atttribute"
);
my $object = $retrieved_objs[0];
unless (($object) {
    die("Get Extensible Attribute Definition object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
```

```
print "Get Extensible Attribute Definition object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
       or die("Remove Extensible Attribute Definition object failed: ",
                $session->status_code() . ":" . $session->status_detail());
print "Extensible Attribute Definition object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::ExtensibleAttributeDef::Descendants - an action for the extensible attributes that exist on descendants.

DESCRIPTION

An object that provides the action for extensible attributes that exist on descendants.

CONSTRUCTOR

```
my $descendants = Infoblox::Grid::ExtensibleAttributeDef::Descendants->new(
    option_without_ea => "INHERIT" | "NOT_INHERIT",             # optional
    option_with_ea    => "RETAIN" | "CONVERT" | "INHERIT",      # optional
    option_delete_ea  => "RETAIN" | "REMOVE",                   # optional
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to configure and retrieve attribute values of the extensible attributes that exist on descendants based on the corresponding action.

option_delete_ea( )

Use this method to set or retrieve the action for objects that contain inheritable extensible attributes if a parent object is deleted.

Parameter

Valid value is "RETAIN" or "REMOVE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $descendants->option_delete_ea();
#Modify attribute value
$descendants->option_delete_ea('RETAIN');
```

option_with_ea( )

Use this method to set or retrieve the action for objects that contain inheritable extensible attributes.

Parameter

Valid value is "RETAIN", "CONVERT" or "INHERIT".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $descendants->option_with_ea();
#Modify attribute value
$descendants->option_with_ea('INHERIT');
```

option_without_ea( )

Use this method to set or retrieve the action for objects that do not contain inheritable extensible attributes.

Parameter

Valid value is "INHERIT" or "NOT_INHERIT".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $descendants->option_without_ea();
#Modify attribute value
$descendants->option_without_ea('NOT_INHERIT');
```

NAME

Infoblox::Grid::ExtensibleAttributeDef::ListValue - Extensible Attribute Definition List Value object.

DESCRIPTION

The Extensible Attribute Definition List Value object is used to store values for an extensible attribute object defined as the "list" type.

CONSTRUCTOR

```
my $ext_attr_def = Infoblox::Grid::ExtensibleAttributeDef::ListValue->new(
    value                => $string,                                          #Required
);
```

METHODS

This section describes all the methods that you can use to set and retrieve the values of an Extensible Attribute Definition List Value object.

value( )

Use this method to set or retrieve the value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Parameter is a string.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get value
my $value = $ext_attr_def_value->value();
#Modify value
$ext_attr_def_value->value($value);
```

NAME

Infoblox::Grid::FileDistribution - Grid FileDistribution object.

DESCRIPTION

You can configure the file distribution properties of a grid. You can enable and disable TFTP, HTTP, and FTP services, and set their operational parameters.

CONSTRUCTOR

The Infoblox::Grid::FileDistribution object is automatically generated upon the successful installation of the Infoblox appliance. It does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a grid member FileDistribution object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my $object   = $session->get(
   object    => "Infoblox::Grid::FileDistribution",
   );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the enable_tftp Property.
$object->enable_tftp("true");
#Submit modification
my $response = $session->modify( $object );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the file distribution properties of a grid member.

allow_uploads( )

Use this method to enable or disable file uploads for the grid.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the file uploads or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting allow_uploads
$allow_uploads = $grid->allow_uploads( );
#Modifying allow_uploads
$grid->allow_uploads("true");
```

backup_storage( )

Use this method to control whether distributed files are included in the backup or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the backup of distributed files or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting backup_storage
$backup_storage = $grid->backup_storage( );
#Modifying backup_storage
$grid->backup_storage("true");
```

current_usage( )

Use this method to retrieve the current usage of the allocated space.

Parameter

The value is the percentage of the usage of the allocated space expressed in tenth of a %. Valid values are from 0 to 1000.

Returns

The method returns the attribute value.

Example

```
#Getting current_usage
$current_usage = $grid->current_usage( );
```

enable_anonymous_ftp( )

Use this method to enable or disable anonymous FTP access for the grid.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable anonymous FTP access or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_anonymous_ftp
$enable_anonymous_ftp = $grid->enable_anonymous_ftp( );
```

```
#Modifying enable_anonymous_ftp
$grid->enable_anonymous_ftp("true");
```

global_status( )

Use this method to retrieve the overall status of all grid members.

Parameter

The method returns the "worst" status among all grid members. Valid values are "FAILED", "INACTIVE", "UNKNOWN", "WARNING" or "WORKING".

Returns

The method returns the attribute value.

Example

```
#Getting global_status
$global_status = $grid->global_status( );
```

storage_limit( )

Use this method to set the maximum TFTP storage allowed on the grid.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The maximum storage size expressed in Megabytes. Valid values are from 1 to 10000.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting storage_limit
$storage_limit = $grid->storage_limit( );
#Modifying storage_limit
$grid->storage_limit(2000);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as modify and get. This sample also includes error handling for the operations.

#Preparation prior to grid FileDistribution object operations

```
#PROGRAM STARTS: Include all the modules that will be used

use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Get and modify a Grid FileDistribution object

```
# Get and modify the grid FileDistribution property object.
my $object = $session->get(
    object => "Infoblox::Grid::FileDistribution",
);

 unless ($object) {
      die("get grid FileDistribution failed: ",
```

```
        $session->status_code() . ":" . $session->status_detail());
    }
    print "grid FileDistribution get successful\n";

#Modifying the value of the specified object
$object->enable_anonymous_ftp("true");

#Apply the changes
$session->modify($object)
    or die("modify grid FileDistribution failed: ",
        $session->status_code() . ":" . $session->status_detail());

print "FileDistribution grid object modified successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::FileDistributionDir - Grid FileDistributionDir object.

DESCRIPTION

The FileDistributionDir object is used to add, get, modify, and remove directories that store files for a file distribution service.

CONSTRUCTOR

```
my $dir = Infoblox::Grid::FileDistributionDir->new(
    name        => $string,             #Required
);
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a FileDistributionDir object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct the file distribution directory object
my $dir = Infoblox::Grid::FileDistributionDir->new(
    name        => "mydir",
);
# Submit for addition
my $response = $session->add( $dir );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific FileDistributionDir object:

 name          - Required. User name in string format.
```

Example

```
my @retrieved_objs = $session->get(
    object      => "Infoblox::Grid::FileDistributionDir",
    name        => "mydir" );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use method to rename a file distribution directory.
$dir->name("mynewdir");
# Submit modification
my $response = $session->modify( $dir );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, use `get()` or `search()` to retrieve the specific object first, and then submit this object for removal.

Example

```
# Get the user objects with the same starting name
my @retrieved_objs = $session->get(
    object      => "Infoblox::Grid::FileDistributionDir",
    name        => "mydir" );
# find the desired object from the retrieved list.
my $dir = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $dir );
```

Infoblox::Session->search( )

Use this method to search for FileDistributionDir objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific FileDistributionDir object:

 name          - Required. Directory name in string format. Only the exact match is supported (that
is, exactly the same as 'get' method).
```

Example

```
# search for all FileDistributionDir objects with name "mydir"
my @retrieved_objs = $session->search(
    object      => "Infoblox::Grid::FileDistributionDir",
    name        => "mydir");
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a FileDistributionDir object.

name( )

Use this method to set or retrieve the name of a file distribution directory.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Text with the name of the file distribution directory. Enter the complete path to the file distribution directory, including all existing intermediate directories.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name of the file distribution directory
my $name = $file_distribution->name();
#Modify name of the file distribution directory (i.e. rename the directory)
$file_distribution->name("mynewdir");
#Create a new subdirectory 'subdir' under 'mynewdir' ('mynewdir' must exist)
$file_distribution->name("mynewdir/subdir");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a FileDistributionDir object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
               );

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a FileDistributionDir object

```
my $dir = Infoblox::Grid::FileDistributionDir->new(
    name        => "mydir",
);

unless ($dir) {
       die("Construct file distribution directory object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "FileDistributionDir object created successfully\n";

#Add the file distribution dir object to the Infoblox appliance through a session
$session->add($dir)
       or die("Add FileDistributionDir object failed: ",
               $session->status_code() . ":" . $session->status_detail());
print "FileDistributionDir object added to server successfully\n";
```

#Search for a file distribution directory

```
my @retrieved_objs = $session->search(
               object      => "Infoblox::Grid::FileDistributionDir",
               name        => "mydir"
              );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search FileDistributionDir object failed: ",
               $session->status_code() . ":" . $session->status_detail());
}
print "Search FileDistributionDir object found at least 1 matching entry\n";
```

#Get and modify a FileDistributionDir object

```
#Get the file distribution dir object from Infoblox appliance through a session
my @retrieved_objs = $session->get(
            object      => "Infoblox::Grid::FileDistributionDir",
            name        => "mydir",
);
my $object = $retrieved_objs[0];

unless ($object) {
       die("Get FileDistributionDir object failed: ",
               $session->status_code() . ":" . $session->status_detail());
}
print "Get FileDistributionDir object found at least 1 matching entry\n";

#Modify the name of the FileDistributionDir object (that is, rename the directory)
$object->name("mynewdir");

#Apply the changes.
$session->modify($object)
       or die("Modify User object failed: ",
               $session->status_code() . ":" . $session->status_detail());
print "FileDistributionDir object modified successfully \n";
```

#Remove a FileDistributionDir object

```
#Get a FileDistributionDir object through the session
my @retrieved_objs = $session->get(
            object      => "Infoblox::Grid::FileDistributionDir",
            name        => "mynewdir",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get FileDistributionDir object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get FileDistributionDir object found at least 1 matching entry\n";

#Submit an object for removal
$session->remove($object)
       or die("Remove FileDistributionDir object failed: ",
                $session->status_code() . ":" . $session->status_detail());
print "FileDistributionDir object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::GlobalSmartFolder - Global Smart Folder object.

DESCRIPTION

A Global Smart Folder object is used for data organization.

CONSTRUCTOR

```
 my $group = Infoblox::Grid::GlobalSmartFolder->new(
     name                => $string,                                    #Required
     comment             => $string,                                    #Optional
/ Default is undefined
     group_bys           => [$GroupbyItem1, $GroupbyItem2],             #Optional
/ Default is undefined
     query_items         => [$QueryItem1, $QueryItem2],                 #Optional
/ Default is undefined
 );
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a Global Smart Folder object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct the QueryItem in-memory object
my $query_item1 = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                => "location",
    operator            => "eq",
    value               => "Santa Clara",
);

#Construct the GlobalSmartFolder object
my $group_by_state = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                    enable_grouping => 'true',
                                                    value => "State",
                                                    value_type => "EXTATTR",
                                                   );

my $smart_folder = Infoblox::Grid::GlobalSmartFolder->new(
    name                => "smartfolder1",
    comment             => "global smart folder",
    group_bys           => [$group_by_state],
    query_items         => [$query_item1],
```

```
);
# Submit for addition
my $response = $session->add( $smart_folder );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific GlobalSmartFolder object:

 name      - Required. GlobalSmartFolder name in string format.
 comment   - Optional. Comment in string format.
```

Example

```
my @retrieved_objs = $session->get(
    object     => "Infoblox::Grid::GlobalSmartFolder",
    name       => "smartfolder1" );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment.
$smart_folder->comment("This is a modified comment");
# Submit modification
my $response = $session->modify( $smart_folder );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, use `get()` or `search()` to retrieve the specific object first, and then submit this object for removal.

Example

```
# Get the GlobalSmartFolder objects using a name
my @retrieved_objs = $session->get(
    object     => "Infoblox::Grid::GlobalSmartFolder",
    name       => "smartfolder1" );
# find the desired object from the retrieved list.
my $desired_smart_folder = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_smart_folder );
```

Infoblox::Session->search( )

Use this method to search for Global Smart Folder objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific GlobalSmartFolder object:

 name      - Optional. GlobalSmartFolder name in string format (regular expression).
 comment   - Optional. Comment in string format (regular expression).
```

Example

```
# search for all GlobalSmartFolder objects that start with "smartfolder"
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::GlobalSmartFolder",
    name   => "smartfolder.*" );
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a GlobalSmartFolder object.

comment( )

Use this method to set or retrieve the comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Pertinent information about the global smart folder. Comment in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $smart_folder->comment();
#Modify comment
$smart_folder->comment("This is the modified comment for smartfolder1");
```

group_bys( )

Use this method to set or retrieve the group_bys value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::SmartFolder::GroupBy object(s). The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $group_by_state = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                    enable_grouping => 'true',
                                                    value => "State",
                                                    value_type => "EXTATTR",
                                                   );
#Get group_by value
my $group_by = $smart_folder->group_bys();
#Modify group_bys value
$smart_folder->group_bys([$group_by_state]);
```

name( )

Use this method to set or retrieve the name of a global smart folder.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Text with the name of the global smart folder.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $smart_folder->name();
```

query_items( )

Use this method to set or retrieve the query items. If query items are not specified when you `add()` a smart folder, the server automatically assigns a default query item for the smart folder. This default query item is "type=Network/Zone/Range/Member". This ensures that objects are included in searches for these 4 types, by default. When you `modify()` a smart folder, the server keeps the query items provided by the client and does not add the default items.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::SmartFolder::QueryItem object(s). The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get query items
my $query_items = $smart_folder->query_items();

#Modify query items
my $query_item1 = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                => "location",
    operator            => "eq",
    value               => "Santa Clara",
);
$smart_folder->query_items([$query_items1]);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to an GlobalSmartFolder object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
              master   => "192.168.1.2", #appliance host ip
              username => "admin",       #appliance user login
              password => "infoblox"     #appliance password
              );

unless ($session) {
       die("Construct session failed: ",
              Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

# Add a network with extensible attributes

my %extensible_attributes=(
    'Region' => 'Santa Clara County',
    'Country' => 'USA',
    'State' => 'California',
    'Site' => 'Santa Clara',
    'Building' => 'HQ',
    'VLAN' => '1',
    );

my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/24",
    extensible_attributes => \%extensible_attributes,
    );
unless ($network) {
  die("Construct Network failed: ",
      Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network created successfully\n";

$session->add($network)
  or die("Add Network object failed: ",
      $session->status_code() . ":" . $session->status_detail());
print "Network object added to server successfully\n";
```

#Create a GlobalSmartFolder object

```
my $query_item = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                    => "Country",
    is_extensible_attribute => "true",
    operator                => "eq",
    value                   => "USA",
    );

unless ($query_item) {
  die("Construct query item object failed: ",
      Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Smart folder query item object created successfully\n";

my $group_by_country = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                        enable_grouping => 'true',
                                                        value => "Country",
                                                        value_type => "EXTATTR",
                                                       );

my $smart_folder = Infoblox::Grid::GlobalSmartFolder->new(
    name                    => "my_folder_global",
    comment                 => "my global folder",
    query_items             => [$query_item],
    group_bys               => [$group_by_country],
    );

unless ($smart_folder) {
  die("Construct global smart folder object failed: ",

NAME

Infoblox::Grid::HostNameRewritePolicy - a structure for storing hostname rewrite policies.

DESCRIPTION

An Infoblox::Grid::HostNameRewritePolicy object represents a hostname rewrite policy.

CONSTRUCTOR

```
my $policy = Infoblox::Grid::HostNameRewritePolicy->new(
     name                => $string,           # Required
     valid_characters    => $string,           # Required
     replacement_character => $string,         # Required
     is_grid_default     => "true" | "false",  # Optional / Default value is "false"
);
```

MODULE METHODS

The following functions can be applied to an Infoblox::Grid::HostNameRewritePolicy object.

Infoblox::Grid::DHCP->protocol_hostname_rewrite_policies( )

Use this function to add or retrieve hostname rewrite policies. See Infoblox::Grid::DHCP->protocol_hostname_rewrite_policies() for parameters and return values.

Example

```
#Get Grid DHCP object
my @retrieved_objs = $session->get(
       object => "Infoblox::Grid::DHCP",
       grid   => "Infoblox"
);
my $griddhcp = $retrieved_objs[0];

#Modify protocol_hostname_rewrite_policies
my $policies = $griddhcp->protocol_hostname_rewrite_policies();
push(@$policies, $policy);
$griddhcp->protocol_hostname_rewrite_policies($policies);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Infoblox::Grid::HostNameRewritePolicy object.

is_grid_default( )

Use this method to set or retrieve the grid's default hostname rewrite policy.

Parameter

Specify "true" to set a policy as the grid default hostname rewrite policy or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get is_grid_default
my $is_grid_default = $policy->is_grid_default();
#Modify is_grid_default
$policy->is_grid_default('true');
```

name( )

Use this method to set or retrieve the policy name.

Parameter

String with policy name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $policy->name();
#Modify name
$policy->name('new_policy');
```

replacement_character( )

Use this method to set or retrieve the replacement character.

Parameter

The replacement character.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get replacement_character
my $replacement_character = $policy->replacement_character();
#Modify name
$policy->replacement_character('-');
```

pre_defined( )

Use this method to retrieve a predefined hostname rewrite policy. This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get pre_defined
my $pre_defined = $policy->pre_defined();
```

valid_characters( )

Use this method to set or retrieve permitted characters for a hostname.

Parameter

String with permitted characters for a hostname.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid_characters
my $valid_characters = $policy->valid_characters();
#Modify valid_characters
$policy->valid_characters('A-Z0-9_');
```

NAME

Infoblox::Grid::HSM::AllGroup - All HSM groups.

DESCRIPTION

This is a read-only object which allows reading of all hsm groups.

CONSTRUCTOR

The Infoblox::Grid::HSM::AllGroup object is a read-only object and does not require manual construction.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to the Infoblox::Grid::HSM::AllGroup object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my $allgroup = $session->get(object => "Infoblox::Grid::HSM::AllGroup");
```

METHODS

This section describes all the methods that you can use to retrieve the attribute values of the Infoblox::Grid::HSM::AllGroup object.

groups( )

Use this method to retrieve the list of HSM groups. This attribute is read-only and cannot be modified.

Parameter

None

Returns

The method returns the attribute value as an array reference that contains Infoblox::Grid::HSM::Thales::Group and Infoblox::Grid::HSM::SafeNet::Group object(s).

Example

```
#Get groups
my $groups = $allgroup->groups();
```

NAME

Infoblox::Grid::HSM::SafeNet - SafeNet HSM (Hardware Security Module) Server object

DESCRIPTION

An Infoblox::Grid::HSM::SafeNet object represents a server configured in the SafeNet HSM group.

CONSTRUCTOR

```
my $hsm_server = Infoblox::Grid::HSM::SafeNet->new(
    name                => $string,                 # Required
    partition_serial    => $uint,                   # Required
    server_certificate  => $string,                 # Required
    disabled            => "true" | "false",        # Optional / Default value is "false"
);
```

MODULE METHODS

The following functions can be applied to a SafeNet HSM Server object.

Infoblox::Grid::HSM::SafeNet::Group->hsm_servers( )

Use this function to add or retrieve SafeNet HSM servers in the SafeNet HSM group. See Infoblox::Grid::HSM::SafeNet::Group->hsm_servers() for parameters and return values.

Example

```
#Construct a SafeNet HSM Group
my $hsm_group = Infoblox::Grid::HSM::SafeNet::Group->new(
    name          => 'SafeNetGroup',
    passphrase    => 'PassPhrase',
    hsm_servers   => [],
    hsm_version   => "LunaSA_4",
);

# Configure the SafeNet HSM server in the SafeNet HSM Group object.
my $response = $hsm_group->hsm_servers([$hsm_server]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Infoblox::Grid::HSM::SafeNet object.

disabled( )

Use this method to set or retrieve the disabled setting.

Parameter

Specify "true" to disable the SafeNet HSM Server object or "false" to enable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value as "true" or "false".

Example

```
#Get disabled flag
my $disabled = $hsm_server->disabled();

#Modify disabled flag
$hsm_server->disabled("true");
```

is_fips_compliant( )

Use this method to retrieve the FIPS compliant mode status. This attribute is read-only and cannot be modified.

Parameter

None

Returns

The method returns the attribute value as "true" or "false".

Example

```
#Get is_fips_compliant flag
my $is_fips_compliant = $hsm_server->is_fips_compliant();
```

name( )

Use this method to set or retrieve the IP address or the domain name for the HSM.

Parameter

String with the IP address or the domain name for the HSM.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $hsm_server->name();

#Modify name
$hsm_server->name("SafeNet");
```

partition_capacity( )

Use this method to retrieve the partition capacity percentage used. This attribute is read-only and cannot be modified.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get partition_capacity
my $partition_capacity = $hsm_server->partition_capacity();
```

partition_id( )

Use this method to retrieve the partition label on the HSM. This attribute is read-only and cannot be modified.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get partition_id
my $partition_id = $hsm_server->partition_id();
```

partition_serial( )

Use this method to set or retrieve the serial number of the partition on the HSM.

Parameter

An unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get partition_serial
my $partition_serial = $hsm_server->partition_serial();

#Modify partition_serial
$hsm_server->partition_serial(12345);
```

server_certificate( )

Use this method to generate the server certificate of the SafeNet HSM server. This attribute is write-only and cannot be retrieved.

Parameter

String with the content of the server certificate or a reference to a file.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set server_certificate as string
$hsm_server->server_certificate($cert);

#Set server_certificate as reference to a file
$hsm_server->server_certificate('/tmp/safenet/cert.pem');
```

status( )

Use this method to retrieve the status of the SafeNet HSM server. This attribute is read-only and cannot be modified.

Parameter

None

Returns

The method returns the attribute value as "UP" or "DOWN".

Example

```
#Get status
my $status = $hsm_server->status();
```

NAME

Infoblox::Grid::HSM::SafeNet::Group - SafeNet HSM (Hardware Security Module) Group object

---

DESCRIPTION

Hardware Security Modules (HSMs) are used for secure private key storage, and key generation and zone-signing offloading.

CONSTRUCTOR

```
 my $hsm_group = Infoblox::Grid::HSM::SafeNet::Group->new(
     name                    => $string,                                  #Required
     passphrase              => $string,                                  #Required
     hsm_servers             => [$safenet1, ...],                         #Required
     hsm_version             => "LunaSA_4" | "LunaSA_5" | "LunaSA_6",     #Required
     comment                 => $string,                                  #Optional / Default
value is empty
 );
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a SafeNet HSM Group object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $hsm_group = Infoblox::Grid::HSM::SafeNet::Group->new(
    name                    => "SafeNetGroup",
    passphrase              => "PassPhrase",
    comment                 => "This is a test SafeNet HSM Group",
    hsm_servers             => [$safenet1],
    hsm_version             => "LunaSA_4",
    );

#Submit for addition
my $response = $session->add($hsm_group);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::HSM::SafeNet::Group",
    name   => "SafeNetGroup");
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment of a SafeNet HSM Group object.
$hsm_group->comment("This is modified SafeNet HSM Group object");

# Submit modification
my $response = $session->modify($hsm_group);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` to retrieve the object, and then submit it for removal.

Example

```
#Get the objects with the specified name.
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::HSM::SafeNet::Group",
    name   => "SafeNetGroup");

#Find the desired object on the retrieved list.
my $desired_hsmgroup = $retrieved_objs[0];

# Submit for removal
my $response = $session->remove($desired_hsmgroup);
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Example

```
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::HSM::SafeNet::Group",
    name   => "SafeNetGroup");
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an HSM Group object.

comment( )

Use this method to set or retrieve a descriptive comment.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $hsm_group->comment();

#Modify comment
$hsm_group->comment("Modified comment");
```

name( )

Use this method to set or retrieve the name of the SafeNet HSM Group object.

Parameter

Desired name for the SafeNet HSM Group object in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $hsm_group->name();

#Modify name
$hsm_group->name("SafeNetGroup2")
```

passphrase( )

Use this method to set the passphrase that is used to unlock the key store. This is a write-only attribute.

Parameter

The valid value is a string, which cannot include a tab and carriage return.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify passphrase
$hsm_group->passphrase("pass1234");
```

hsm_servers( )

Use this method to set or retrieve the list of SafeNet servers in a SafeNet HSM Group object.

Parameter

The valid value is an array reference that contains Infoblox::Grid::HSM::SafeNet object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get SafeNet HSM servers list
my $hsm_servers = $hsm_group->hsm_servers();

#Modify SafeNet HSM servers list
my $safenet_server1 = Infoblox::Grid::HSM::SafeNet->new(
   name               => 'server1',
   partition_serial   => 123,
   server_certificate => '/tmp/safenet/cert1.pem',
);
my $safenet_server2 = Infoblox::Grid::HSM::SafeNet->new(
   name               => 'server2',
   partition_serial   => 456,
   server_certificate => '/tmp/safenet/cert2.pem',
);

$hsm_group->hsm_servers([$safenet_server1,$safenet_server2]);
```

hsm_version( )

Use this method to set or retrieve the HSM version of the SafeNet HSM Group.

Parameter

The value can be either "LunaSA_4", "LunaSA_5" or "LunaSA_6".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value of "LunaSA_4", "LunaSA_5" or "LunaSA_6".

Example

```
#Get hsm_version
my $hsm_version = $hsm_group->hsm_version();

#Modify hsm_version
$hsm_version->hsm_version("LunaSA_4");
```

serial_number( )

Use this method to retrieve the serial number of the SafeNet HSM Group. This attribute is read-only and cannot be modified.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get serial_number
my $serial_number = $hsm_group->serial_number();
```

status( )

Use this method to retrieve the status of the SafeNet HSM Group. This attribute is read-only and cannot be modified.

Parameter

None

Returns

The method returns the attribute value of "UP" or "DOWN".

Example

```
#Get status
my $status = $hsm_group->status();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify and remove. This sample also includes error handling for the operations.

#Preparation prior to getting and modifying a grid member object

```
use strict;
use Infoblox;

#refers to Infoblox Appliance IP address
my $host_ip = "192.168.1.2";

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a SafeNet HSM Group object

```
my $safenet_server = Infoblox::Grid::HSM::SafeNet->new(
```

```
    name                => "20.0.0.1",
    partition_serial    => 1234,
    server_certificate  => '/tmp/safenet/cert.pem',
    );
unless (safenet_server) {
       die("Construct safenet server object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "SafeNet server object created successfully\n";

my $hsm_group = Infoblox::Grid::HSM::SafeNet::Group->new(
    name         => "SafeNet Group",
    passphrase   => 'pass',
    hsm_servers  => [safenet_server],
    hsm_version  => "LunaSA_4",
    );
unless ($hsm_group) {
       die("Construct SafeNet HSM Group object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "SafeNet HSM Group object created successfully\n";

#Add the SafeNet HSM object to appliance through session
my $response = $session->add($hsm_group);

unless ($response) {
    die("Add SafeNet HSM Group failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print "SafeNet HSM Group added successfully \n";
```

#Get and modify the SafeNet HSM Group object

```
#Get SafeNet HSM Group through session
my @retrieved_objs = $session->get(
    object   => "Infoblox::Grid::HSM::SafeNet::Group",
    name     => "SafeNet Group",
    );
my $hsm_group = $retrieved_objs[0];

unless ($hsm_group) {
    die("Get SafeNet HSM Group object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Get SafeNet HSM Group successful \n";

# Modify one of the attributes of the selected SafeNet HSM Group.

$hsm group->comment("Modified hsm group object");

#Applying the changes
$session->modify($hsm_group)
   or die("Modify SafeNet HSM Group failed",
            $session->status_code() . ":" . $session->status_detail());
print "SafeNet HSM Group modified successfully \n";
```

#Remove the grid member object

```
#Get SafeNet HSM Group through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::HSM::SafeNet::Group",
    name   => "SafeNet Group",
    );
my $desired_hsm_group = $retrieved_objs[0];

unless ($desired_hsm_group) {
    die("Get SafeNet HSM Group object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print "Get SafeNet HSM Group successful \n";

#Submit the object for removal
$session->remove($desired_hsm_group)
    or die("Remove SafeNet HSM Group failed",
           $session->status_code() . ":" . $session->status_detail());
print "SafeNet HSM Group removed successfully \n";
```

```

NAME

Infoblox::Grid::HSM::Thales - Thales HSM (Hardware Security Module) Server object

---

DESCRIPTION

An Infoblox::Grid::HSM::Thales object represents a server configured in the HSM group.

CONSTRUCTOR

```
my $hsm_server = Infoblox::Grid::HSM::Thales->new(
    remote_ip       => $ipv4addr,                   # Required
    keyhash         => $string,                     # Required
    disabled        => "true" | "false",            # Optional / Default value is "false"
    remote_port     => $num,                        # Optional / Default value is 9004
);
```

MODULE METHODS

The following functions can be applied to an HSM Server object.

Infoblox::Grid::HSM::Thales::Group->thales_hsm( )

Use this function to add or retrieve HSM servers in the HSM group. See Infoblox::Grid::HSM::Thales::Group->thales_hsm() for parameters and return values.

Example

```
#Construct an HSM Group
my $hsm_group = Infoblox::Grid::HSM::Thales::Group->new(
    name                    => "HSM Group",
    key_server_ip           => "10.0.0.1",
    key_server_port         => 9004,
    comment                 => "A new HSM Group ",
    thales_hsm              => []
);

# Configure the HSM server in the HSM Group object.
my $response = $hsm_group->thales_hsm([$thales_server]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Infoblox::Grid::HSM::Thales object.

disabled( )

Use this method to set or retrieve the disabled setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to disable the HSM Server object or "false" to enable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disabled flag
my $disabled = $thales_server->disabled();
#Modify disabled flag
$thales_server->disabled("true");
```

keyhash( )

Use this method to set or retrieve the key hash used to authenticate the HSM.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired key hash in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get key hash
my $key = $thales_server->keyhash();
#Modify key hash
$thales_server->keyhash("123hashxyz");
```

remote_ip( )

Use this method to set or retrieve the IP address of the Thales HSM server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The IPv4 address of the Thales HSM server.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the Thales HSM server IP address
my $remote_ip = $thales_server->remote_ip();
#Modify the Thales HSM server IP address
$thales_server->remote_ip("20.0.0.9");
```

remote_port( )

Use this method to set or retrieve the remote port setting of the Thales HSM server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are between 1 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get remote port
my $remote_port = $thales_server->remote_port();
#Modify remote port
$thales_server->remote_port(9012);
```

remote_esn( )

Use this method to retrieve the Electronic Serial Number (ESN) of the Thales HSM server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Returns

The method returns the attribute value.

Example

```
#Get remote ESN
my $remote_esn= $thales_server->remote_esn();
```

status( )

Use this method to retrieve the status of the Thales HSM server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Returns

The method returns the attribute value as "UP" or "DOWN".

Example

```
#Get status
my $status= $thales_server->status();
```

NAME

Infoblox::Grid::HSM::Thales::Group - Thales HSM Group object

DESCRIPTION

Hardware Security Modules (HSMs) are used for secure private key storage, and key generation and zone-signing offloading.

CONSTRUCTOR

```
 my $hsm_group = Infoblox::Grid::HSM::Thales::Group->new(
     key_server_ip           => $ipv4addr,                                   #Required
     name                    => $string,                                     #Required
     thales_hsm              => [$thales1, ...],                             #Required
     card_name               => $string,                                     #Required if
"protection" is "SOFTCARD"
     pass_phrase             => $string,                                     #Required if
"protection" is "SOFTCARD"
     comment                 => $string,                                     #Optional / Default
value is empty
     key_server_port         => $num,                                        #Optional / Default
value is 9004
     protection              => "MODULE" | "SOFTCARD" ,                      #Optional / Default
value is Module
 );
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to an HSM Group object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $hsm_group = Infoblox::Grid::HSM::Thales::Group->new(
    name                    => "HSM Group",
    key_server_ip           => "10.0.0.1",
    key_server_port         => 9004,
    comment                 => "A new HSM Group ",
    thales_hsm              => [$thales1]
    );

#Submit for addition
```

```
my $response = $session->add($hsm_group);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::HSM::Thales::Group",
    key_server_ip   => "10.0.0.1");
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment of an HSM Group object.
$hsm_group->comment("This is modified HSM Group object");
# Submit modification
my $response = $session->modify($hsm_group );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` to retrieve the object, and then submit it for removal.

Example

```
#Get the objects with the specified key_server_ip.
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::HSM::Thales::Group",
    key_server_ip   => "10.0.0.1");

#Find the desired object on the retrieved list.
my $desired_hsmgroup = $retrieved_objs[0];

# Submit for removal
my $response = $session->remove($desired_hsmgroup);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an HSM Group object.

card_name( )

Use this method to set or retrieve the name of the softcard used by the HSM Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name for the softcard in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get softcard name
my $card_name = $hsm_group->card_name();
#Modify softcard name
$hsm_group->card_name("Softcard 1")
```

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $hsm_group->comment();
#Modify comment
$hsm_group->comment("Modified HSM Group");
```

key_server_ip( )

Use this method to set or retrieve the key file server IP address of an HSM Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The IPv4 address of the key file server.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get key server IP address
my $key_server_ip = $hsm_group->key_server_ip();
#Modify key server IP address
$hsm_group->key_server_ip("10.0.0.5");
```

key_server_port( )

Use this method to set or retrieve the port number used by the key file server configured in the HSM Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an unsigned integer ranging from 0 to 65535.The default value is 9004.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get key server port
my $key_server_port = $hsm_group->key_server_port();
#Modify key server port
$hsm_group->key_server_port(9012);
```

name( )

Use this method to set or retrieve the name of the HSM Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name for the HSM Group object in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $hsm_group->name();
#Modify name
$hsm_group->name("HSM GROUP 2")
```

pass_phrase( )

Use this method to set the passphrase that is used to unlock the key store. This is a write-only attribute.

Include the specified parameter to set the attribute value.

Parameter

The valid value is a string, which cannot include a tab and carriage return.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify passphrase
$hsm_group->pass_phrase("pass1234");
```

protection( )

Use this method to set or retrieve the protection type of an HSM Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are "MODULE" and "SOFTCARD".The default value is "MODULE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get protection
my $protection = $hsm_group->protection();
#Modify protection
$grid_member->protection("SOFTCARD");
```

thales_hsm( )

Use this method to set or retrieve the list of Thales servers in an HSM Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::HSM::Thales object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get Thales HSM list
my $thales_hsm = $hsm_group->thales_hsm();
#Modify Thales HSM list
my $thales_hsm1 = Infoblox::Grid::HSM::Thales->new(
    remote_ip              => "20.0.0.1",
    keyhash                => "a123",
);

my $thales_hsm2 = Infoblox::Grid::HSM::Thales->new(
    remote_ip              => "20.0.0.5",
    keyhash                => "b456",
```

```
);

$hsm_group->thales_server([$thales_hsm1,$thales_hsm2]);
```

status( )

Use this method to retrieve the status of the remote file server used in the HSM Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Returns

The method returns the attribute value of "UP" or "DOWN" .

Example

```
#Get status
my $status = $hsm_group->status();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify and remove. This sample also includes error handling for the operations.

#Preparation prior to getting and modifying a grid member object

```
use strict;
use Infoblox;

#refers to Infoblox Appliance IP address
my $host_ip = "192.168.1.2";

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an HSM Group object

```
my $thales_server = Infoblox::Grid::HSM::Thales->new(
    remote_ip     => "20.0.0.1",
    keyhash       => "1234hash",
    remote_port   => 9012,
    );
unless ($thales_server) {
       die("Construct thales server object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Thales server object created successfully\n";

my $hsm_group = Infoblox::Grid::HSM::Thales::Group->new(
    key_server_ip     => "20.0.0.1",
    key_server_port   => 9007,
    );
unless ($hsm_group) {
       die("Construct HSM Group object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "HSM Group object created successfully\n";

#Add the HSM object to appliance through session
my $response = $session->add( $hsm_group );

unless ($response) {
    die("Add HSM Group failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"HSM Group added successfully \n";
```

#Get and modify the HSM Group object

```
#Get HSM Group through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::HSM::Thales::Group",
    key_server_ip     => "20.0.0.1",
    );
my $hsm_group = $retrieved_objs[0];

unless ($hsm_group) {
    die("Get HSM Group object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Get HSM Group successful \n";

# Modify one of the attributes of the selected HSM Group.

$hsm group->comment("Modified hsm group object");

#Applying the changes
$session->modify($hsm_group)
   or die("Modify HSM Group failed",
            $session->status_code() . ":" . $session->status_detail());
print"HSM Group modified successfully \n";
```

#Remove the grid member object

```
#Get HSM Group through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::HSM::Thales::Group",
    key_server_ip     => "20.0.0.1"
    );
my $desired_hsm_group = $retrieved_objs[0];

unless ($desired_hsm_group) {
    die("Get HSM Group object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Get HSM Group successful \n";

#Submit the object for removal
$session->remove( $desired_hsm_group )
    or die("Remove HSM Group failed",
           $session->status_code() . ":" . $session->status_detail());
print"HSM Group removed successfully \n";

####PROGRAM ENDS####
```

NAME

Infoblox::Grid::HTTPProxyServerSetting - An Infoblox Grid HTTP Proxy Server Setting object.

DESCRIPTION

The Grid HTTP Proxy Server Setting object provides information about HTTP Proxy Server configuration.

CONSTRUCTOR

```
my $http_proxy_setting = Infoblox::Grid::HTTPProxyServerSetting->new(
    address                     => $fqdn | $ipv4addr | $ipv6addr, # Required
    port                        => $uint,                         # Required
    enable_username_and_password => 'true' | 'false',             # Optional / Default is 'false'
    enable_proxy                => 'true' | 'false',              # Optional / Default is 'false'
    enable_content_inspection   => 'true' | 'false',              # Optional / Default is 'false'
    verify_cname                => 'true' | 'false',              # Optional / Default is 'false'
    comment                     => $string,                       # Optional / Default is undefined
    username                    => $string,                       # Optional / Default is undefined
    password                    => $string,                       # Optional / Default is undefined
    certificate                 => $string,                       # Optional / Default is undefined
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions are available to be applied to a HTTP Proxy Server object.

Infoblox::Grid->http_proxy_server_setting( )

Use this method to set or retreive the Grid HTTP proxy server settings. See Infoblox::Grid->http_proxy_server_setting() for parameters andreturn values.

Example

```
#Get http_proxy_server_setting value
my $http_proxy_server_setting = $grid->http_proxy_server_setting();

#Modify http_proxy_server_setting value
$grid->http_proxy_server_setting($http_proxy_setting);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a HTTP Proxy Server Setting object.

address( )

Use this method to set or retrieve the address of the HTTP Proxy Server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains Fully-Qualified Domain Name (FQDN), IPv4 address or IPv6 address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address value
my $address = $obj->address();

#Modify address value
$obj->address('10.0.0.1');
```

certificate( )

Use this method to set the path to a CA Certificate used in a content inspection by a HTTP Proxy Server. This is a write-only attribute.

Include the specified parameter to set the attribute value.

Parameter

The valid value is a string which contains a path to certificate.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify certificateibute value
$obj->certificate('/path/to/cert.pem');
```

comment( )

Use this method to set or retrieve the descriptive comment for HTTP Proxy Server configuration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $comment = $obj->attr();

#Modify comment value
$obj->comment('desired comment');
```

enable_content_inspection( )

Use this method to set or retrieve the flag that indicates whether the HTTPS packets content inspection by HTTP Proxy Server is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable HTTPS packets content inspection or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_content_inspection value
my $enable_content_inspection = $obj->enable_content_inspection();

#Modify enable_content_inspection value
$obj->enable_content_inspection('true');
```

enable_username_and_password( )

Use this method to set or retrieve the flag that indicates whether the use of username and password for the connectivity of HTTP proxy server is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to use username and password for testing the connectivity of HTTP proxy server or 'false' to disallow it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_username_and_password value
my $enable_username_and_password = $obj->enable_username_and_password();

#Modify enable_username_and_password value
$obj->enable_username_and_password('true');
```

enable_proxy( )

Use this method to set or retrieve the flag that indicates whether HTTP Proxy Server is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable HTTP Proxy Server or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_proxy value
my $enable_proxy = $obj->enable_proxy();

#Modify enable_proxy value
$obj->enable_proxy('true');
```

password( )

Use this method to set the HTTP Proxy password. This is a write-only attribute.

Include the specified parameter to set the attribute value.

Parameter

The valid value is a desired password in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify password value
$obj->password('pass');
```

port( )

Use this method to set or retrieve the HTTP Proxy Server port it listens to.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 0 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get port value
my $port = $obj->port();

#Modify port value
$obj->port(10000);
```

username( )

Use this method to set or retrieve the HTTP Proxy user name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired user name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get username value
my $username = $obj->username();

#Modify username value
$obj->username('user1');
```

verify_cname( )

Use this method to set or retrieve the flag which indicates whether the CNAME record query verification is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable CNAME record query verification or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get verify_cname value
my $verify_cname = $obj->verify_cname();

#Modify verify_cname value
$obj->verify_cname('true');
```

NAME

Infoblox::Grid::InformationalBannerSetting - The informational banner setting.

DESCRIPTION

The informational banner setting object that controls the banner displayed on the login page of Grid Manager.

CONSTRUCTOR

```
 my $color = "BLACK" | "BLUE" | "BROWN" | "CYAN" | "GREEN" | "MAGENTA" | "ORANGE" | "PURPLE" | "RED" |
"YELLOW";

 my $informational = Infoblox::Grid::InformationalBannerSetting->new(
     enable    => "true" | "false", #Mandatory
     color     => $color,           #Mandatory
     message   => $string,          #Optional / Default is empty
 );
```

MODULE METHODS

The following functions are available to apply to an informational banner setting object.

Infoblox::Grid->informational_banner_setting( )

Use this function to specify the informational banner settings for the Grid. See Infoblox::Grid->informational_banner_setting() for parameters and return values.

Example

```
      my $grid = $session->get(object => 'Infoblox::Grid');

      my $banner = Infoblox::Grid::InformationalBannerSetting->new(enable => 'true', color => 'BLUE',
    message => 'Informational message');
      $grid->informational_banner_setting($banner);
      my $response = $session->modify($grid);
      unless($response) {
           die("Modify grid failed: ",
                 session->status_code() . ":" . session->status_detail());
      }
      print "Grid banner setting modified successfully\n";
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of an informational banner setting object.

enable( )

Use this method to set the enable flag.

Parameter

Specify "true" to enable the banner or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable
my $enable = $banner->enable();
#Modify enable
$banner->enable("true");
```

color( )

Use this method to set the color of the message that will be displayed on the login page of Grid Manager.

Parameter

A string containing the color. Banner colors can be one of the following: 'BLACK', 'BLUE', 'BROWN', 'CYAN', 'GREEN', 'MAGENTA', 'ORANGE', 'PURPLE', 'RED', 'YELLOW'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get color
my $color = $banner->color();
#Modify color
$banner->color("RED");
```

message( )

Use this method to set the message that will be displayed on the login page of Grid Manager.

Parameter

A string containing the message.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get message
my $message = $banner->message();
#Modify message
$banner->message("Test message");
```

Infoblox::Grid::IPValidationInfo - IP Validation information

- NAME
- DESCRIPTION
- CONSTRUCTOR
- MODULE METHODS
  - Infoblox::Session->add( ) and Infoblox::Session->modify( )
- METHODS
  - address( )
  - parent( )
- SAMPLE CODE
- AUTHOR
- SEE ALSO
- COPYRIGHT

NAME

Infoblox::Grid::IPValidationInfo - IP Validation information

DESCRIPTION

When submitting add or modify requests that contain IPs returned by the next_available_ip functionality, this object can be passed to ensure that these IPs are unique and that concurrent additions and modifications containing the same IPs will fail.

CONSTRUCTOR

```
my $member = Infoblox::Grid::IPValidationInfo->new(
    address        => $ipaddr,         #Required
    parent         => $obj,            #Required
);
```

MODULE METHODS

The following functions are available for an IP validation info object.

Infoblox::Session->add( ) and Infoblox::Session->modify( )

The object can be passed in the ip_validation option. For usage information, see the sample code section.

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of an IP validation info object.

address( )

Use this method to set or retrieve the address.

Parameter

The valid value is an IPv4 or IPv6 address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address
my $address = $vip->address();
#Modify address
$vip->address('10.0.0.1');
```

parent( )

Use this method to set the parent object for the validation. This is the object from which the next available IP was retrieved, and it must be an object retrieved from the server.

Parameter

The valid value is an Infoblox::DHCP::Range, Infoblox::DHCP::IPv6Range, Infoblox::DHCP::Network, Infoblox::DHCP::IPv6Network

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get parent
my $net = $member->vip();
#Modify vip
$member->vip($net2);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to the insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $host_ip   = "192.168.1.2";
my $host_name = "infoblox.localdomain";

my $session = Infoblox::Session->new(
              master   => $host_ip,      #appliance host ip
              username => "admin",       #appliance user login
              password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
              Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DNS Zone object

```
my $default_view = Infoblox::DNS::View->new(name => "default");

my $memberns1 = Infoblox::DNS::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => $host_ip,
    lead     => "false",
    stealth  => "false"
);

#To add zone test.com in the default view
my $firstzone = Infoblox::DNS::Zone->new(
    name         => "test.com",
    views        => [$default_view],
    email        => "admin\@infoblox.com",
    comment      => "add a zone test.com",
    primary      => $memberns1,
    );

unless($firstzone){
       die("Construct test.com zone object failed: ",
              Infoblox::status_code(). ":" .Infoblox::status_detail());
       }
print "test.com zone object created successfully.\n";

$session->add($firstzone)
    or die("Add zone for test.com failed: ",
              $session->status_code(). ":" .$session->status_detail());

print"Zone test.com added successfully.\n";
```

#Create a DHCP Network

```
my $memberdhcp = Infoblox::DHCP::Member->new(
            name     => "infoblox.localdomain",
            ipv4addr => $host_ip,
           );

my  $network = Infoblox::DHCP::Network->new(
            network => "10.0.0.0/8",
            comment => "add network",
            members => [$memberdhcp],
             );
unless($network){
       die("Construct test.com zone object failed: ",
               Infoblox::status_code(). ":" .Infoblox::status_detail());
       }
print "Network created successfully\n";

my $response = $session->add($network)
       or die("Add Network failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Network added successfully\n";
```

#Fetch a next available IP from the network

```
my $nip = $network->next_available_ip();
```

#Create a validation object for this IP

```
my $vip = Infoblox::Grid::IPValidationInfo->new(
   parent  => $network,
   address => $nip,
);
```

#Add a DNS A record with this IP and validation

```
#Construct a DNS A object
my $bind_a = Infoblox::DNS::Record::A->new(
    name     => "bind_a.test.com",
    comment  => " this is a demo bind_a record ",
    ipv4addr => $nip,
);
unless ($bind_a) {
   die("Construct DNS record A failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DNS A object created successfully\n";

#Add the DNS A record object to Infoblox Appliance through a session
$session->add($bind_a, ip_validation => [$vip])
    or die("Add record A failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DNS A object added to server successfully\n";
```

#Cleanup

```
$session->remove($bind_a)
    or die("Remove record A failed: ",
        $session->status_code() . ":" . $session->status_detail());

$session->remove($network)
    or die("Remove network failed: ",
        $session->status_code() . ":" . $session->status_detail());

$session->remove($firstzone)
    or die("Remove zone failed: ",
        $session->status_code() . ":" . $session->status_detail());

####PROGRAM ENDS####

NAME

Infoblox::Grid::KerberosKey - Grid kerberos key object.

DESCRIPTION

This object is used to manage kerberos keys for GSS-TSIG.

CONSTRUCTOR

```
#Constructor for an Grid KerberosKey object
 my $key = Infoblox::Grid::KerberosKey->new(
    principal => $string,  #Required.
    domain    => $string,  #Optional / Default is undefined
    version   => $num,     #Optional / Default is undefined
  );
```

MODULE METHODS

The following functions are available to be applied to an KerberosKey object.

Infoblox::Grid::DNS->gss_tsig_keys( )

Use this function to specify a Kerberos key at the grid level on the Infoblox appliance. See Infoblox::Grid::DNS->gss_tsig_keys() for parameters and return values.

Example

```
#Create a Kerberos object.
my $key = Infoblox::Grid::KerberosKey->new(
                  principal => 'host/appliance.ivan.test@LADYBUG.LOCAL',
                  domain => 'JACKIE.LOCAL',
                  version => '3',
);

#Configure kerberos key on the Infoblox grid object
my $response = $grid->gss_tsig_keys([$key]);
```

Infoblox::Grid::DHCP->gss_tsig_keys( )

Use this function to specify a Kerberos key at the grid level on the Infoblox appliance. See Infoblox::Grid::DHCP->gss_tsig_keys() for parameters and return values.

Example

```
#Create a Kerberos object.
my $key = Infoblox::Grid::KerberosKey->new(
                principal => 'host/appliance.ivan.test@LADYBUG.LOCAL',
                domain => 'JACKIE.LOCAL',
                version => '3',
              );

#Configure kerberos key on the Infoblox grid object
my $response = $grid->gss_tsig_keys([$key]);
```

Infoblox::Grid::Member::DNS->gss_tsig_keys( )

Use this function to specify a Kerberos key at the member level on the Infoblox appliance. See Infoblox::Grid::Member::DNS->gss_tsig_keys() for parameters and return values.

Example

```
#Create a KerberosKey object.
my $key = Infoblox::Grid::KerberosKey->new(
                principal => 'host/appliance.ivan.test@LADYBUG.LOCAL',
                domain => 'JACKIE.LOCAL',
                version => '3',
);

#Configure KerberosKey on the Infoblox member object
my $response = $member->gss_tsig_keys([$key]);
```

Infoblox::Grid::Member::DHCP->gss_tsig_keys( )

Use this function to specify a Kerberos key at the member level on the Infoblox appliance. See Infoblox::Grid::Member::DHCP->gss_tsig_keys() for parameters and return values.

Example

```
 #Create a KerberosKey object.
  my $key = Infoblox::Grid::KerberosKey->new(
                principal => 'host/appliance.ivan.test@LADYBUG.LOCAL',
                domain => 'JACKIE.LOCAL',
                version => '3',
              );

#Configure KerberosKey on the Infoblox member object
my $response = $member->gss_tsig_keys([$key]);
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a Kerberos key object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Kerberos key object:

 principal - Required. The principal of the Kerberos key object you want to retrieve.
```

Example

```
my @retrieved_objs = $session->get(
    object    => "Infoblox::Grid::KerberosKey",
    principal => "my-principal");
```

Infoblox::Session->remove( )

Use this method to remove a Kerberos key object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific Kerberos key object, and then submit this object for removal.

Example

```
# Get the objects with the same principal
my @retrieved_objs = $session->get(
    object    => "Infoblox::Grid::KerberosKey",
    principal => "my-principal");
# Find the desired object from the retrieved list.
my $desired_kerberos_key = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_kerberos_key );
```

Infoblox::Session->search( )

Use this method to search for Kerberos key objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a Kerberos key object:

 principal - Required. The principal of the Kerberos key object you want to retrieve (regular
expression is supported).
```

Example

```
# search for all grid member objects
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::KerberosKey",
    principal => ".*");
```

METHODS

This section describes all the methods that you can used to configure and retrieve the attribute value of a KerberosKey object.

enctype( )

Use this method to retrieve the encryption type for the KerberosKey object. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get enctype value
my $enctype = $key->enctype();
```

domain( )

Use this method to set or retrieve the domain of the KerberosKey object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired domain in string format with a maximum of 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain
my $domain = $key->domain();
#Modify domain
$key->domain("my-domain");
```

in_use( )

Use this method to retrieve the flag used to indicate whether the key has been assigned to a member. This is a read-only attribute.

Parameter

None

Returns

The return value is "true" if KerberosKey object has been assigned to a member and "false" if it hasn't.

Example

```
#Get in_use value
my $in_use = $key->in_use();
```

principal( )

Use this method to set or retrieve the principal string of the KerberosKey object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired principal in string format with a maximum of 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get principal
my $string = $key->principal();
#Modify principal
$key->principal("my-principal");
```

version( )

Use this method to set or retrieve the version number of the KerberosKey object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter an unsigned integer between 0 and 4294967295.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get version
my $version = $key->version();
#Modify version
$key->version("5");
```

upload_timestamp( )

Use this method to retrieve the timestamp when the KerberosKey object was uploaded. This is a read-only attribute.

Parameter

None

Returns

The return value is the date and time in the ISO 8601 extended format (e.g. 2008-10-21T10:56:33Z or 2008-10-21T10:56:33.001Z).

Example

```
#Get upload_timestamp value
my $upload_timestamp = $key->upload_timestamp();
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to an object such as create, get, and remove an object. Also this sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
 use strict;
 use Infoblox;

 #Create a session to the Infoblox appliance
 my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
 );
 unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
 }
 print "Session created successfully\n";
```

#import kerberos key object

```
my $result = $session->import_data(
    type       => "keytab",
    path       => "/infoblox/tests/datasets/dnsone.keytab",
    service => 'dhcp',
   );

unless($result) {
       die("import kerberos key object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "import kerberos key object successfully\n";
```

#retrieve kerberos key object

```
my @keys = $session->get(
   object    => "Infoblox::Grid::KerberosKey",
   principal => 'host/appliance.ivan.test@LADYBUG.LOCAL',
 );

 unless ($key) {
       die("Get KerberosKey object failed: ",
            $session->status_code() . ":" . $session->status_detail());
  }
  print "Get KerberosKey object found at least 1 matching entry\n";

my $grid_dhcp = $session->get(
   object  => 'Infoblox::Grid::DHCP',
   cluster => 'Infoblox',
   );
unless ($grid_dhcp) {
       die("Get Grid DHCP object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}

$grid_dhcp->gss_tsig_keys([$key]);
$grid_dhcp->kdc_server('test.com');

#Applying the changes to appliance through session.
$session->modify($grid_dhcp)
     or die("modify Grid DHCP properties failed:" ,
      $session->status_code(), $session->status_detail());
print "Grid DHCP properties modified successfully for assigning KerberosKey object\n";
```

#Removing an KerberosKey object

```
# remove the reference to kerberos key
$grid_dhcp->gss_tsig_keys(undef);
$grid_dhcp->kdc_server(undef);

#Applying the changes to appliance through session.
$session->modify($grid_dhcp)
     or die("modify Grid DHCP properties failed:" ,
      $session->status_code(), $session->status_detail());
print "Grid DHCP properties modified successfully for unassigning KerberosKey object\n";
```

```
$session->remove(object => 'Infoblox::Grid::KerberosKey',
                 principal => 'host/appliance.ivan.test@LADYBUG.LOCAL')
     or die("remove KerberosKey object failed:" ,
      $session->status_code(), $session->status_detail());
print "remove KerberosKey object successfully\n";

NAME

Infoblox::Grid::LicenseGridWide - a Grid-wide license object.

DESCRIPTION

A Grid-wide license is assigned and locked to the Grid to activate the licensed feature on all eligible appliances. The Grid-wide license object is used to display infromation related to Grid-wide license (i.e. expiration date, limit value).

CONSTRUCTOR

The Infoblox::Grid::LicenseGridWide object is a read-only object and does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a Grid-wide license object.

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my $retrieved_objs = $session->get(object => "Infoblox::Grid::LicenseGridWide");
```

Infoblox::Session->search( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attributes to search the Grid-wide license object(s):

    "type"  - Optional. The license type.
    "limit" - Optional. The limitation of dynamic license.
    "key"   - Optional. The license string.
```

Example

```
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::LicenseGridWide",
    type   => "DNS"
);
```

Infoblox::Session->remove( )

Use this method to remove a Grid-wide license object from the Infoblox device. See Infoblox::Session->remove() for parameters and return values.

Example

```
#search for a specific object
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::LicenseGridWide",
    type   => "DNS"
);

my $object = $retrieved_objs[0];

#remove the object
my $response = $session->remove($object);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of a Grid-wide license object.

expiration( )

Use this method to retrieve the Grid-wide license expiration timestamp. This is a read-only attribute.

Parameter

None

Returns

The method returns the number of seconds elapsed since January 1, 1970, in UTC format.

Example

```
#Get expiration value
my $expiration = $object->expiration();
```

expiration_status( )

Use this method to retrieve the Grid-wide license expiration status. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get expiration_status value
my $expiration_status = $object->expiration_status();
```

key( )

Use this method to retrieve the license string for the Grid-wide license. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get key value
my $value = $object->key();
```

limit( )

Use this method to retrieve the number of dynamic licenses that can be allocated from the Grid-wide license. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get limit value
my $value = $object->limit();
```

limit_context( )

Use this method to retrieve the context of the license limit. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get limit_context value
my $limit_context = $object->limit_context();
```

type( )

Use this method to retrieve the license type. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get type value
my $value = $object->type();
```

NAME

Infoblox::Grid::LicensePool - License Pool object.

DESCRIPTION

A license pool is a container associated with the Grid and holds dynamic licenses for a specific feature. Licenses in the pool can be dynamically allocated to and deallocated from Grid members. When not in use, dynamic licenses are released back to the pool for future allocation. There is no expiration for dynamic licenses.

CONSTRUCTOR

The Infoblox::Grid::LicensePool object is a read-only object and does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a License Pool object.

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my $retrieved_objs = $session->get(object => "Infoblox::Grid::LicensePool");
```

Infoblox::Session->search( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attributes to search the License Pool object(s):

    "type"  - Optional. The license type.
    "limit" - Optional. The limitation of dynamic license.
    "model" - Optional. The supported vNIOS virtual applaince model.
    "key"   - Optional. The license string.
```

Example

```
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::LicensePool",
```

```
        type    => "DNS"
);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of a License Pool object.

assigned( )

Use this method to retrieve the number of dynamic licenses allocated to vNIOS appliances. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get assigned value
my $value = $object->assigned();
```

expiration( )

Use this method to retrieve the license pool expiration timestamp. This is a read-only attribute.

Parameter

None

Returns

The method returns the number of seconds elapsed since January 1, 1970, in UTC format.

Example

```
#Get expiration value
my $expiration = $object->expiration();
```

expiration_status( )

Use this method to retrieve the license pool expiration status. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get expiration_status value
my $expiration_status = $object->expiration_status();
```

installed( )

Use this method to retrieve the total number of dynamic licenses allowed for this license pool. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get installed value
my $value = $object->installed();
```

key( )

Use this method to retrieve the license string for the license pool. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get key value
my $value = $object->key();
```

limit( )

Use this method to retrieve the total number of available dynamic licenses from the license pool. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get limit value
my $value = $object->limit();
```

limit_context( )

Use this method to retrieve the context of the license limit. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get limit_context value
my $limit_context = $object->limit_context();
```

model( )

Use this method to retrieve the supported vNIOS appliance model. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get model value
my $value = $object->model();
```

subpools( )

Use this method to retrieve dynamic licenses in sub pools. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. An array of Infoblox::Grid::LicenseSubPool objects.

Example

```
#Get subpools value
my $value = $object->subpools();
```

temp_assigned( )

Use this method to retrieve the total number of temporary dynamic licenses allocated to vNIOS appliances. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get temp_assigned value
my $value = $object->temp_assigned();
```

type( )

Use this method to retrieve the license type. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get type value
my $value = $object->type();
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to a License Pool object. This sample code also includes error handling for the operations.

#Preparation prior License Pool fetching

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox device
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);

unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Fetching the License Pool objects

```
my $retrieved_objs=$session->get(object=> "Infoblox::Grid::LicensePool");

unless($retrieved_objs) {
    die("Getting the license pools failed:",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Got the license pools successfully\n";
####PROGRAM ENDS####
```

NAME

Infoblox::Grid::LicensePoolContainer - License Pool Container object.

DESCRIPTION

License Pool Container is the list of all license pools existing for a Grid.

CONSTRUCTOR

The Infoblox::Grid::LicensePoolContainer object is a read-only object and does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a License Pool Container object.

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my $retrieved_objs = $session->get(object => "Infoblox::Grid::LicensePoolContainer");
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of a License Pool Container object.

lpc_uid( )

Use this method to retrieve the world-wide unique ID for the license pool container. This attribute is read-only and cannot be set.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get the unique ID for the license pool container
my $lpc_uid = $license_pool_container->lpc_uid();
```

last_entitlement_update( )

Use this method to retrieve the timestamp of the last entitlement pool update. This attribute is read-only and cannot be set.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get the last entitlement pool update
my $last_entitlement_update = $license_pool_container->last_entitlement_update();
```

update_licenses( )

Use this method to upload new license file.

Parameter

"path" - Required. Path to the signed file with static/dynamic licenses to upload.

Returns

None.

Example

```
$license_pool_container->update_licenses(path => $path_to_license);
```

allocate_licenses( )

Use this method to allocate dynamic licenses to a node.

Parameter

"hwid" - Required. The hardware ID of a physical node to install dynamic licenses to.

"license_pools" - Required. The license pools from which you allocate dynamic licenses. An array containing Infoblox::Grid::LicensePool objects.

Returns

None.

Example

```
$license_pool_container->allocate_licenses(hwid => $hwid,
                                           license_pools => [$licence_pool1, $licence_pool2]);
```

download_pool_status( )

Use this method to to download signed file with static licenses/license pools.

Parameter

None.

Returns

"path" - The path to the file with licenses to download.

Example

```
$hash_with_path = $license_pool_container->download_pool_status();
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to a License Pool object. This sample code also includes error handling for the operations.

#Preparation prior License Pool Container fetching

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox device
my $session = Infoblox::Session->new(
```

```
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);

unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Fetching the License Pool Container objects

```
my $retrieved_objs=$session->get(object=> "Infoblox::Grid::LicensePoolContainer");

unless($retrieved_objs) {
    die("Getting the license pool container failed:",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Got the license pool container successfully\n";
####PROGRAM ENDS####

NAME

Infoblox::Grid::LicenseSubPool - a license subpool object.

DESCRIPTION

The license subpool object shows the license installments that have the same expiry date.

CONSTRUCTOR

The Infoblox::Grid::LicenseSubPool object is a read-only object and does not require manual construction.

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

Infoblox::Grid::LicensePool->subpools( )

Use this method to retrieve the license pool subpools. For parameters and return values see Infoblox::Grid::LicensePool->subpools.

Example

```
#Get subpools value
my $value = $object->subpools();
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of a license subpool object.

expiration( )

Use this method to retrieve the license subpool expiration timestamp. This is a read-only attribute.

Parameter

None

Returns

The method returns the number of seconds elapsed since January 1, 1970, in UTC format.

Example

```
#Get expiration value
my $expiration = $object->expiration();
```

installed( )

Use this method to retrive the total number of dynamic licenses allowed for this license sub pool. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get installed value
my $value = $object->installed();
```

key( )

Use this method to retrieve the license string for the license subpool. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get key value
my $value = $object->key();
```

NAME

Infoblox::Grid::LOM::User - User information for the Lights Out Management functionality.

DESCRIPTION

An Infoblox::Grid::LOM::User object represents a user for the LOM functionality.

CONSTRUCTOR

```
my $user    = Infoblox::Grid::LOM::User->new(
     name     => $string,              # Required
     password => $string,              # Required
     role     => "OPERATOR" | "USER", # Required
     disable  => "true" | "false",     # Required
);
```

MODULE METHODS

The following functions can be applied to a LOM User object.

Infoblox::Grid::Member->bgp_as( )

Use this function to specify BGP Autonomous Systems for the grid member. See Infoblox::Grid::Member->bgp_as() for parameters and return values.

Example

```
#Construct a LOM User
my $lomuser = Infoblox::Grid::LOM::User->new(
     name     => 'username',
     password => 'password',
     role     => 'OPERATOR',
     disable  => 'false,
);

# Configure the LOM user on the grid object
$grid->lom_users([$lomuser]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Infoblox::Grid::LOM::User object.

disable( )

Use this method to set or retrieve the disable flag for the user.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the disable
my $disable = $lom_user->disable();
#Modify the disable
$lom_user->disable('false');
```

name( )

Use this method to set or retrieve the name of the user.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the user in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the name
my $name = $lom_user->name();
#Modify the name
$lom_user->name('username');
```

password( )

Use this method to set the password the user will use to authenticate. This is a write-only attribute.

Include the specified parameter to set the attribute value.

Parameter

The password for the user in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify the password
$lom_user->password('password');
```

role( )

Use this method to set or retrieve the role of the user.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "OPERATOR" and "USER".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the role
my $role = $lom_user->role();
#Modify the role
$lom_user->role('OPERATOR');
```

NAME

Infoblox::Grid::MaxMindDBInfo - an MaxMind Database information object.

DESCRIPTION

The object provides information about the MaxMind database.

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a MaxMindDBInfo object. Note that the object supports only the get method since there is only one such object in the database.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

  binary_major_version - Optional. The major binary version of MaxMind database.
  binary_minor_version - Optional. The minor binary version of MaxMind database.
  build_time           - Optional. The time at which the MaxMind database was built.
  database_type        - Optional. The structure of data records.
  deployment_time      - Optional. The time at which the current MaxMind database was deployed.
  topology_type        - Optional. The MaxMind database topology type.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::DTC::Monitor::TCP',
    database_type => 'GeoLite2-Country',
);
```

MODULE METHODS

Infoblox::DTC->import_maxminddb( )

import_maxminddb( )

Use this method to upload MaxMind Database.

Key Reference

```
Apply the following attribute to upload a MaxMind Database:

    path - Required. The path to a tar archive that contains the MaxMind Database.
```

Returns

The method returns "true" when an upload of a MaxMind Database has been performed successfully, and returns "false" when the operation fails.

Example

```
#upload MaxMind DB
my $res = $dtc->import_maxminddb(path => $path_to_maxminddb);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

binary_major_version( )

Use this method to retrieve the major version of the MaxMind database binary format. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#get binary_major_version value
my $binary_major_version = $maxminddbinfo->binary_major_version();
```

binary_minor_version( )

Use this method to retrieve the minor version of the MaxMind database binary format. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#get binary_minor_version value
my $binary_minor_version = $maxminddbinfo->binary_minor_version();
```

build_time( )

Use this method to retrieve the time when the MaxMind database was built. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#get build_time value
my $build_time = $maxminddbinfo->build_time();
```

database_type( )

Use this method to retrieve the structure of MaxMind database records. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#get database_type value
my $database_type = $maxminddbinfo->database_type();
```

deployment_time( )

Use this method to retrieve the time when the current MaxMind database was deployed. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#get deployment_time value
my $deployment_time = $maxminddbinfo->deployment_time();
```

member( )

Use this method to retrieve the Grid member name on which the current MaxMind database was deployed. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get member value
my $value = $object->member();
```

topology_type( )

Use this method to retrieve the MaxMind database topology type. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The valid return values are 'GEOIP' and 'EA'.

Example

```
#get topology_type value
my $topology_type = $maxminddbinfo->topology_type();
```

NAME

Infoblox::Grid::Member - Grid Member object.

DESCRIPTION

A grid member is a single Infoblox appliance or an HA pair of Infoblox appliances that belong to a grid.

CONSTRUCTOR

```
 my $grid_member = Infoblox::Grid::Member->new(
     gateway                 => $ipv4addr,                                   #Required
     ipv4addr                => $ipv4addr,                                   #Required
     mask                    => $netmask,                                    #Required
     name                    => $fqdn,                                       #Required
     additional_ip_list      => [$Interface1, $ipv4addr2, ...],              #Optional / Default
value is empty
     allow_syslog_clients    => [$ipv4addr | $ipv4_subnet/prefix, ...] | $nacl | undef, #Optional / Default
value is undefined
     bgp_as                  => [$AS1, ...],                                 #Optional / Default
value is empty
     alternate_resolver      => $Nameserver | $Member | $ipv4addr | undef,    #Optional / Default

value depends from the member type.
     pre_provisioning         => $pp,                                      #optional / Default
value is undef. $pp is an Infoblox::Grid:Member::PreProvisioning object
     preserve_if_owns_delegation => "true" | "false"                       #Optional / Default
value is "false"
      );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a grid member object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to take effect. See Infoblox::Session->restart() method.

Example

```
#Construct an object
my $grid_member = Infoblox::Grid::Member->new(
    name                    => "hostname.com",
    ipv4addr                => "3.0.0.2",
    mask                    => "255.0.0.0",
    gateway                 => "3.0.0.1",
    );
#Submit for addition
my $response = $session->add( $grid_member );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific grid member object:

 name - Optional. A name in FQDN (Fully Qualified Domain Name) format.
 ipv4addr  - Optional. The IPv4 address of the member.
 ipv6addr  - Optional. The IPv6 address of the member.
 extattrs  - Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member",
    name   => "hostname.com");
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to take effect. See Infoblox::Session->restart() method.

Example

```
# Use this method to modify comment of grid member.
$grid_member->comment("This is modified object");
# Submit modification
my $response = $session->modify( $grid_member );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member",
    name   => "hostname.com");
#Find the desired object from the retrieved list.
my $desired_gridmember = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_gridmember );
```

Infoblox::Session->search( )

Use this method to search for grid member objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a grid member object:

 name    - Optional. A name in FQDN (Fully Qualified Domain Name) format (regular expression).
 comment - Optional. A comment in string format (regular expression).
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes   - Optional. A hash reference containing extensible attributes.
 ipv4addr  - Optional. The IPv4 address of the member.
 ipv6addr  - Optional. The IPv6 address of the member.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all grid member objects
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::Member",
    name   => ".*\\.com");
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a grid member.

active_position( )

Use this method to retrieve the active server of a grid member.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get active server
my $active_server = $grid_member->active_position();
```

additional_ip_list( )

Use this method to set or retrieve the additional_ip_list of a grid member. This list contains additional interface information that can be used on the member level.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Any object in the list with interface set to "LAN_HA" and ipv6 parameters will be mapped to the toplevel ipv6 methods (ipv6addr, ipv6_cidr, ipv6_enable_auto_config and ipv6_gateway). If such an object is already in the list and is removed, the values of those methods will be cleared.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Member::Interface `object(s)` or IPv4 addresses in string format.

Note that Infoblox::Grid::Member::Interface `object(s)` with interface set to "MGMT" are not supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get additional ip list
my $additional_ip_list = $grid_member->additional_ip_list();
#Modify additional ip list
my $interface_obj = Infoblox::Grid::Member::Interface->new(
        subnet_mask => "255.255.255.255",
        anycast     => "false",
        comment     => "advanced ip config",
        ipv4addr    => "4.3.2.1",
        interface   => "LOOPBACK",
);
$grid_member->additional_ip_list([$interface_obj]);
```

allow_syslog_clients( )

Use this method to set or retrieve the allow_syslog_clients list of a grid member. This list specifies the clients where the syslog messages are logged. This is required only when enable_syslog_proxy is set to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses or networks. To undefine allow_syslog_clients, you must disable the enable_syslog_proxy flag.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get allow syslog clients
my $allow_syslog_clients = $grid_member->allow_syslog_clients();
#Modify allow syslog clients
$grid_member->allow_syslog_clients(["10.10.10.1", "10.10.2.0/24"]);
#Use Infoblox::Grid::NamedACL
$grid_member->allow_syslog_clients($nacl);
```

alternate_resolver( )

Use this method to set or retrieve the alternate_resolver of a grid member. The alternate resolver receives queries from the appliance if it does not receive a response from the preferred name server first.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are Infoblox::DNS::Member object or Infoblox::DNS::Nameserver object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get alternate resolver
my $alternate_resolver = $grid_member->alternate_resolver();
#Modify alternate resolver
my $member1 = Infoblox::DNS::Member->new(
    name           => $host_name,
    ipv4addr       => $host_ip,
    stealth        => "false",
    lead           => "false",
    grid_replicate => "false"
);
$grid_member->alternate_resolver($member1);
#Undef alternate resolver
$grid_member->alternate_resolver(undef);
```

bgp_as( )

Use this method to set or retrieve the BGP configuration for anycast, of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::Member::BGP::AS object(s). Currently, only one Autonomous System (AS) object per grid member is supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get AS list
my $as = $grid_member->bgp_as();
#Modify AS list
my $as1 = Infoblox::Grid::Member::BGP::AS->new(
    as             => 269,
    keepalive      => 4,
    holddown       => 16,
    neighbors      => [ $neighbor ]
);
```

```
$grid_member->bgp_as([$as1]);
```

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $grid_member->comment();
#Modify comment
$grid_member->comment("Modified grid member");
```

config_addr_type( )

Use this method to set or retrieve the configuration type for the address.

Parameter

The valid value is one of the following: "IPv4", "IPv6" or "BOTH".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get config_addr_type
my $config_addr_type = $grid_member->config_addr_type();
#Modify config_addr_type
$grid_member->config_addr_type("IPv4");
```

dscp( )

Use this method to set or retrieve the DSCP value.

Setting this method to a defined value implicitly sets the override_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_dscp attribute to "false".

Note that when dscp is set to a defined value and override_ddscp is set to "false", the last operation takes precedence. Thus the sequence $object->dscp(11); $object->override_dscp("false"); will set override_dscp to "false", and the sequence $object->override_dscp("false"); $object->dscp(11); will result in override_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63 inclusive. The default value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the DSCP value from the member
my $users = $grid_member->dscp();
#Modify the DSCP value
$grid_member->dscp(11);
```

enable_ha( )

Use this method to set or retrieve the HA state of a member. It indicates whether a member is a single appliance or an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_ha flag or "false" to deactivate/unset it. The default value is "false". If set to "false", then all the "node1_xxxx" and "node2_xxxx" attributes but node1_service_status and node1_hwtype are disabled, and "get" does not return those attributes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ha from the member
my $enable_ha = $grid_member->enable_ha();
#Modify enable_ha
$grid_member->enable_ha("true");
```

enable_lom( )

Use this method to set or retrieve the flag that controls whether the LOM functionality is enabled.

Setting this method to a defined value implicitly sets the override_enable_lom method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_enable_lom attribute to "false".

Note that when enable_lom is set to a defined value and override_denable_lom is set to "false", the last operation takes precedence. Thus the sequence $object->enable_lom("true"); $object->override_enable_lom("false"); will set override_enable_lom to "false", and the sequence $object->override_enable_lom("false"); $object->enable_lom("true"); will result in override_enable_lom="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_lom flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_lom from the member
my $lom = $grid_member->enable_lom();
#Modify enable_lom
$grid_member->enable_lom("true");
```

enable_member_redirect( )

Use this method to set or retrieve the flag that controls whether the member will redirect GUI connections to the grid master.

Setting this method to a defined value implicitly sets the override_enable_member_redirect method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_enable_member_redirect attribute to "false".

Note that when enable_member_redirect is set to a defined value and override_denable_member_redirect is set to "false", the last operation takes precedence. Thus the sequence $object->enable_member_redirect("true"); $object->override_enable_member_redirect("false"); will set override_enable_member_redirect to "false", and the sequence $object->override_enable_member_redirect("false"); $object->enable_member_redirect("true"); will result in override_enable_member_redirect="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_member_redirect flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_member_redirect from the member
my $redirect = $grid_member->enable_member_redirect();
#Modify type of member
$grid_member->enable_member_redirect("true");
```

enable_ntp( )

Use this method to set or retrieve the enable_ntp flag of a grid member. Network Time Protocol (NTP) is a protocol designed to synchronize the clocks of computers over a network. This method enables/disables NTP service on the grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_ntp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable ntp flag
my $enable_ntp = $grid_member->enable_ntp();
#Modify enable ntp flag
$grid_member->enable_ntp("true");
```

enable_snmpv3_query( )

Use this method to enable or disable SNMPv3 queries.

Parameter

Specify "true" to enable SNMPv3 queries or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get enable_snmpv3_query
my $enable_snmpv3_query = $gridmember->enable_snmpv3_query();
#Modify enable_snmpv3_query
$gridmember->enable_snmpv3_query("false");
```

enable_snmpv3_traps( )

Use this method to enable or disable SNMPv3 traps.

Parameter

Specify "true" to enable SNMPv3 traps or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get enable_snmpv3_traps
my $enable_snmpv3_traps = $gridmember->enable_snmpv3_traps();
#Modify enable_snmpv3_traps
$gridmember->enable_snmpv3_traps("true");
```

enable_ro_api_access( )

Use this method to enable or disable read-only API access for the Grid Master candidate.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to allow read-only API access or "false" to forbid it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable syslog proxy flag
my $enable_ro_api_access = $grid_member->enable_ro_api_access();
#Modify enable syslog proxy flag
$grid_member->enable_ro_api_access("true");
```

enable_syslog_proxy( )

Use this method to set or retrieve the enable_syslog_proxy flag of a grid member. When enabled, the member receives syslog messages from specified devices, such as syslog servers and routers, and then forwards these messages to an external syslog server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_syslog_proxy flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable syslog proxy flag
my $enable_syslog_proxy = $grid_member->enable_syslog_proxy();
#Modify enable syslog proxy flag
$grid_member->enable_syslog_proxy("true");
```

external_ntp_servers_enabled( )

Use this method to set or retrieve the external_ntp_servers_enabled flag of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

When this flag is set to "false", the member does not use the configured list of NTP (Network Time Protocol) servers.

When this flag is set to "true", the member uses the configured list of NTP servers. If no NTP servers are configured on the member, it uses the NTP servers configured on the grid.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get external_ntp_servers_enabled flag
my $external_ntp_servers_enabled= $grid_member->external_ntp_servers_enabled();
#Modify external_ntp_servers_enabled flag
$grid_member->external_ntp_servers_enabled("true");
```

exclude_grid_master_as_ntp_server( )

Use this method to set or retrieve the exclude_grid_master_as_ntp_server flag of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

When this flag is set to "true", the member does not use the grid master as an NTP (Network Time Protocol) time source. The default value of this parameter is "false", which means that by default the Grid Master is used as one of the time sources for Grid Member.

Note that setting this flag to "true" may have a detrimental effect on the database integrity of the member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get exclude_grid_master_as_ntp_server flag
my $exclude_grid_master_as_ntp_server= $grid_member->exclude_grid_master_as_ntp_server();
#Modify exclude_grid_master_as_ntp_server flag
$grid_member->exclude_grid_master_as_ntp_server("true");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Grid Member object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $grid_member->extattrs();
#Modify extattrs
$grid_member->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a Grid Member object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $member->extensible_attributes();
#Modify extensible attributes
$member->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

gateway( )

Use this method to set or retrieve the gateway IP address of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get gateway
my $gateway = $grid_member->gateway();
#Modify gateway
$grid_member->gateway("3.0.0.1");
```

ha_node2_port_duplex( )

Use this method to specify or retrieve the duplex setting of the HA port on node 2 of an HA grid member. Note: Use this method in combination with ha_node2_port_speed. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are "Half" or "Full". The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ha_node2_port_duplex
my $ha_node2_port_duplex = $obj->ha_node2_port_duplex();
#Modify ha_node2_port_duplex
$obj->ha_node2_port_duplex("Half");
```

ha_node2_port_speed( )

Use this method to set or retrieve the connection speed of the HA port on node #2 of an HA grid member. Note: Use this method in combination with ha_node2_port_duplex. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are 10, 100 or 1000. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ha_node2_port_speed
my $ha_node2_port_speed = $obj->ha_node2_port_speed();
#Modify ha_node2_port_speed
$obj->ha_node2_port_speed(10);
```

ha_port_duplex( )

Use this method to specify or retrieve the duplex setting of the HA port on node 1 of an HA grid member. Note: Use this method in combination with ha_port_speed. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are "Half" or "Full". The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ha_port_duplex
my $ha_port_duplex = $obj->ha_port_duplex();
#Modify ha_port_duplex
$obj->ha_port_duplex("Half");
```

ha_port_speed( )

Use this method to set or retrieve the connection speed of the HA port on node 1 of an HA grid member. Note: Use this method in combination with ha_port_duplex. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are 10, 100 or 1000. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ha_port_speed
my $ha_port_speed = $obj->ha_port_speed();
#Modify ha_port_speed
$obj->ha_port_speed(10);
```

ha_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the HA port on node 1 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->ha_reserved_interface();
#Modify attribute value
$grid_member->ha_reserved_interface($interface);
```

paid_nios( )

Use this method to retrieve whether the grid member is Paid NIOS.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get Paid NIOS status
my $paid_nios = $grid_member->paid_nios();
```

hwplatform( )

Use this method to retrieve the hardware platform of the member appliance.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get hardware platform
my $hwplatform = $grid_member->hwplatform();
```

hwid( )

Use this method to retrieve the hardware ID of the member appliance.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get hardware ID
my $hwid = $grid_member->hwid();
```

is_dscp_capable( )

Use this method to retrieve the flag that describes whether a Grid member supports DSCP.

Parameter

The method retruns "true" if the member supports DSCP, and "false" otherwise.

Returns

The method returns the attribute value.

Example

```
#Get is_dscp_capable
my $is_dscp_capable = $grid_member->is_dscp_capable();
```

ipv4addr( )

Use this method to set or retrieve the IPv4 address of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $grid_member->ipv4addr();
#Modify ipv4addr
$grid_member->ipv4addr("3.0.0.3");
```

ipv6addr( )

Use this method to set or retrieve the LAN IPv6 address of the grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting any of the ipv6 methods in the member (ipv6addr, ipv6_cidr, ipv6_enable_auto_config and ipv6_gateway) is equivalent to creating an Infoblox::Grid::Member::Interface object with those fields set and interface set to "LAN_HA", if there is already such an object it will be modified, if not it will be created. See the additional_ip_list section for more information.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 IPv6 address
my $ipv6addr = $grid_member->ipv6addr();
#Modify LAN2 IPv6 address
$grid_member->ipv6addr("2001::2");
```

ipv6_cidr( )

Use this method to set or retrieve the CIDR of the grid member. Required only when ipv6addr is specified.

See ipv6addr for more information on how this impacts additional_ip_list.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the netmask in CIDR format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 cidr
my $cidr = $grid_member->cidr();
#Modify LAN2 cidr
$grid_member->cidr("64");
```

ipv6_enable_auto_config( )

Use this method to enable/disable IPv6 auto-configuration of the grid member.

See ipv6addr for more information on how this impacts additional_ip_list.

When IPv6 auto-configuration is enabled, a gateway is not needed since it will be automatically discovered.

Parameter

Specify "true" to enable IPv6 auto-configuration or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get IPv6 auto-configuration
my $ipv6_autoconfig_enabled = $grid_member->ipv6_enable_auto_config();
#Modify IPv6 auto-configuration
$grid_member->ipv6_enable_auto_config("true");
```

ipv6_gateway( )

Use this method to set or retrieve the LAN IPv6 gateway of the grid member.

See ipv6addr for more information on how this impacts additional_ip_list.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 IPv6 gateway
my $ipv6_gateway = $grid_member->ipv6_gateway();
#Modify LAN2 IPv6 gateway
$grid_member->ipv6_gateway("2001::1");
```

ipv6_static_routes( )

Use this method to set or retrieve the IPv6 static routes list of a grid member. This list contains the static routes of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Member::IPv6StaticRoute object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get static routes list
my $ipv6_static_routes = $grid_member->ipv6_static_routes();
#Modify static routes list
my $route = Infoblox::Grid::Member::IPv6StaticRoute->new(
        "address" => "2002::5",
        "cidr"    => 64
        "gateway" => "2002::1",
);
$grid_member->ipv6_static_routes([$route]);
```

ipv6_vlan_id( )

Use this method to set or retrieve the IPv6 VLAN ID of a grid member.

Parameter

Valid values are unsigned integers between 1 and 4095, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->ipv6_vlan_id();
#Modify attribute value
$grid_member->ipv6_vlan_id(10);
```

lan_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the LAN port on a single grid member or on node 1 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->lan_reserved_interface();
#Modify attribute value
$grid_member->lan_reserved_interface($interface);
```

lan1_dscp( )

Use this method to set or retrieve the DSCP value of the IPv4 LAN1 port.

Setting this method to a defined value implicitly sets the override_lan1_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_lan1_dscp attribute to "false".

Note that when dscp is set to a defined value and override_lan1_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->lan1_dscp(11); $object->override_lan1_dscp("false"); will set override_lan1_dscp to "false", and the sequence $object->override_lan1_dscp("false"); $object->lan1_dscp(11); will result in override_lan1_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->lan1_dscp();
#Modify attribute value
$grid_member->lan1_dscp(11);
```

lan1_ipv6_dscp( )

Use this method to set or retrieve the DSCP value of the IPv6 LAN1 port.

Setting this method to a defined value implicitly sets the override_lan1_ipv6_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_lan1_ipv6_dscp attribute to "false".

Note that when dscp is set to a defined value and override_lan1_ipv6_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->lan1_ipv6_dscp(11); $object->override_lan1_ipv6_dscp("false"); will set override_lan1_ipv6_dscp to "false", and the sequence $object->override_lan1_ipv6_dscp("false"); $object->lan1_ipv6_dscp(11); will result in override_lan1_ipv6_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->lan1_ipv6_dscp();
#Modify attribute value
$grid_member->lan1_ipv6_dscp(11);
```

lan2_dscp( )

Use this method to set or retrieve the DSCP value of the IPv4 LAN2 port.

Setting this method to a defined value implicitly sets the override_lan1_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_lan1_dscp attribute to "false".

Note that when dscp is set to a defined value and override_lan2_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->lan2_dscp(11); $object->override_lan2_dscp("false"); will set override_lan2_dscp to "false", and the sequence $object->override_lan2_dscp("false"); $object->lan2_dscp(11); will result in override_lan2_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->lan2_dscp();
#Modify attribute value
$grid_member->lan2_dscp(11);
```

lan2_gateway( )

Use this method to set or retrieve the gateway IP address of the LAN2 port. Note that to configure the LAN2 port, the lan2_port flag must

be set to 'true'.

lan2_ipv4addr, lan2_mask, lan2_gateway attributes are required if one of them is defined.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 gateway
my $lan2_gateway = $grid_member->lan2_gateway();
#Modify LAN2 gateway
$grid_member->lan2_gateway("4.0.0.1");
```

lan2_ipv4addr( )

Use this method to set or retrieve the LAN IP address of the LAN2 port. Note that to configure the LAN2 port, the lan2_port flag must be set to 'true'.

lan2_gateway, lan2_ipv4addr, lan2_mask attributes are required if one of them is defined.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 IPv4 address
my $lan2_ipv4addr = $grid_member->lan2_ipv4addr();
#Modify LAN2 IPv4 address
$grid_member->lan2_ipv4addr("4.0.0.2");
```

lan2_ipv6addr( )

Use this method to set or retrieve the LAN IPv6 address of the LAN2 port. Note that to configure the LAN2 port, the lan2_port flag must be set to 'true'.

lan2_ipv6addr, lan2_ipv6_cidr, lan2_ipv6_gateway attributes are required if one of them is defined.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 IPv6 address
my $lan2_ipv6addr = $grid_member->lan2_ipv6addr();
#Modify LAN2 IPv6 address
$grid_member->lan2_ipv6addr("2001::2");
```

lan2_ipv6_cidr( )

Use this method to set or retrieve the CIDR of the LAN2 port. Note that to configure the LAN2 port, the lan2_port flag must be set to 'true'.

lan2_ipv6addr, lan2_ipv6_cidr, lan2_ipv6_gateway attributes are required if one of them is defined.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the netmask in CIDR format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 cidr
my $lan2_cidr = $grid_member->lan2_cidr();
#Modify LAN2 cidr
$grid_member->lan2_cidr("64");
```

lan2_ipv6_dscp( )

Use this method to set or retrieve the DSCP value of the IPv6 LAN2 port.

Setting this method to a defined value implicitly sets the override_lan2_ipv6_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_lan2_ipv6_dscp attribute to "false".

Note that when dscp is set to a defined value and override_lan2_ipv6_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->lan2_ipv6_dscp(11); $object->override_lan2_ipv6_dscp("false"); will set override_lan1_ipv6_dscp to "false", and the sequence $object->override_lan2_ipv6_dscp("false"); $object->lan2_ipv6_dscp(11); will result in override_lan2_ipv6_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->lan2_ipv6_dscp();
#Modify attribute value
$grid_member->lan2_ipv6_dscp(11);
```

lan2_ipv6_enable( )

Use this method to enable/disable IPv6 configuration of the LAN2 interface.

Parameter

Specify "true" to enable IPv6 configuration or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->lan2_ipv6_enable();
#Modify attribute value
$grid_member->lan2_ipv6_enable("true");
```

lan2_ipv6_enable_auto_config( )

Use this method to enable/disable IPv6 auto-configuration of the LAN2 interface.

When IPv6 auto-configuration is enabled, a gateway is not needed since it will be automatically discovered.

Parameter

Specify "true" to enable IPv6 auto-configuration or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get IPv6 auto-configuration
my $ipv6_autoconfig_enabled = $grid_member->lan2_ipv6_enable_auto_config();
#Modify IPv6 auto-configuration
$grid_member->lan2_ipv6_enable_auto_config("true");
```

lan2_ipv6_gateway( )

Use this method to set or retrieve the LAN IPv6 gateway of the LAN2 port. Note that to configure the LAN2 port, the lan2_port flag must be set to 'true'.

lan2_ipv6addr, lan2_ipv6_cidr, lan2_ipv6_gateway attributes are required if one of them is defined.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 IPv6 gateway
my $lan2_ipv6_gateway = $grid_member->lan2_ipv6_gateway();
#Modify LAN2 IPv6 gateway
$grid_member->lan2_ipv6_gateway("2001::1");
```

lan2_ipv6_vlan_id( )

Use this method to set or retrieve the VLAN ID of the IPv6 LAN2 port. Note that to configure the LAN2 port, the lan2_port flag must be set to 'true'.

Parameter

Valid values are unsigned integers between 1 and 4095, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->lan2_ipv6_vlan_id();
#Modify attribute value
$grid_member->lan2_ipv6_vlan_id(10);
```

lan2_mask( )

Use this method to set or retrieve the netmask of the LAN2 port. Note that to configure the LAN2 port, the lan2_port flag must be set to 'true'.

lan2_ipv4addr, lan2_mask, lan2_gateway attributes are required if one of them is defined.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Netmask address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.255.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 mask
my $lan2_mask = $grid_member->lan2_mask();
#Modify LAN2 mask
$grid_member->lan2_mask("255.255.0.0");
```

lan2_node2_port_duplex( )

Use this method to specify or retrieve the duplex setting of the LAN2 port on node 2 of an HA grid member. Note: Use this method in combination with lan2_node2_port_speed. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are "Half" or "Full". The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lan2_node2_port_duplex
my $lan2_node2_port_duplex = $obj->lan2_node2_port_duplex();
#Modify lan2_node2_port_duplex
$obj->lan2_node2_port_duplex("Half");
```

lan2_port( )

Use this method to set or retrieve the LAN2 port flag of a single grid member or node 1 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the lan2_port flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 port flag
my $lan2_port = $grid_member->lan2_port();
#Modify LAN2 port flag
$grid_member->lan2_port("true");
```

lan2_node2_port_speed( )

Use this method to set or retrieve the connection speed of the LAN2 port on node 2 of an HA grid member. Note: Use this method in combination with lan2_node2_port_duplex. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are 10, 100 or 1000. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lan2_node2_port_speed
my $lan2_node2_port_speed = $obj->lan2_node2_port_speed();
#Modify lan2_node2_port_speed
$obj->lan2_node2_port_speed(10);
```

lan2_port_duplex( )

Use this method to specify or retrieve the duplex setting of the LAN2 port on a single grid member or on node 1 of an HA grid member. Note: Use this method in combination with lan2_port_speed. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are "Half" or "Full". The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lan2_port_duplex
my $lan2_port_duplex = $obj->lan2_port_duplex();
#Modify lan2_port_duplex
$obj->lan2_port_duplex("Half");
```

lan2_port_speed( )

Use this method to set or retrieve the connection speed of the LAN2 port on a single grid member or on node 1 of an HA grid member. Note: Use this method in combination with lan2_port_duplex. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are 10, 100 or 1000. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lan2_port_speed
my $lan2_port_speed = $obj->lan2_port_speed();
#Modify lan2_port_speed
$obj->lan2_port_speed(10);
```

lan2_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the LAN2 port on a single grid member or on node 1 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->lan2_reserved_interface();
#Modify attribute value
$grid_member->lan2_reserved_interface($interface);
```

lan2_router_id( )

Use this method to set or retrieve the LAN2 virtual router ID of a grid member. Required only when the member is an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number with the LAN2 router identification. Valid values are from 1 through 255.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN2 virtual router ID
my $lan2_router_id = $grid_member->lan2_router_id();
#Modify LAN2 virtual router ID
$grid_member->lan2_router_id("123");
```

lan2_vlan_id( )

Use this method to set or retrieve the VLAN ID of the IPv4 LAN2 port. Note that to configure the LAN2 port, the lan2_port flag must be set to 'true'.

Parameter

Valid values are unsigned integers between 1 and 4095, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->lan2_vlan_id();
#Modify attribute value
$grid_member->lan2_vlan_id(10);
```

lan_node2_port_duplex( )

Use this method to specify or retrieve the duplex setting of the LAN port on node 2 of an HA grid member. Note: Use this method in combination with lan_node2_port_speed. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are "Half" or "Full". The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lan_node2_port_duplex
my $lan_node2_port_duplex = $obj->lan_node2_port_duplex();
#Modify lan_node2_port_duplex
$obj->lan_node2_port_duplex("Half");
```

lan_node2_port_speed( )

Use this method to set or retrieve the connection speed of the LAN port on node 2 of an HA grid member. Note: Use this method in combination with lan_node2_port_duplex. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are 10, 100 or 1000. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lan_node2_port_speed
my $lan_node2_port_speed = $obj->lan_node2_port_speed();
#Modify lan_node2_port_speed
$obj->lan_node2_port_speed(10);
```

lan_port_duplex( )

Use this method to specify or retrieve the duplex setting of the LAN port on a single grid member or on node 1 of an HA grid member.. Note: Use this method in combination with lan_port_speed. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are "Half" or "Full". The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lan_port_duplex
my $lan_port_duplex = $obj->lan_port_duplex();
#Modify lan_port_duplex
$obj->lan_port_duplex("Half");
```

lan_port_speed( )

Use this method to set or retrieve the connection speed of the LAN port on a single grid member or on node 1 of an HA grid member.. Note: Use this method in combination with lan_port_duplex. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are 10, 100 or 1000. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lan_port_speed
my $lan_port_speed = $obj->lan_port_speed();
#Modify lan_port_speed
$obj->lan_port_speed(10);
```

lcd_input( )

Use this method to set or retrieve the lcd_input flag of a grid member. This flag enables/disables the Liquid Crystal Display (LCD) input buttons on the front panel of the appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the lcd_input flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lcd input flag
```

```
my $lcd_input = $grid_member->lcd_input();
#Modify lcd input flag
$grid_member->lcd_input("true");
#Undef lcd input flag
$grid_member->lcd_input(undef);
```

lcd_autodim( )

Use this method to set or retrieve the number of seconds before the Liquid Crystal Display (LCD) on the front panel of the appliance automatically dims.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of seconds before the LCD automatically dims. Valid values are between 5 and 3600. The default value is 30.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lcd_autodim
my $lcd_autodim = $grid_member->lcd_autodim();
#Modify the autodim value
$grid_member->lcd_autodim(60);
```

lcd_brightness( )

Use this method to set or retrieve the brightness level of the LCD on the front panel of the appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are between 1 and 10. The default value is 7.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lcd_brightness
my $lcd_brightness = $grid_member->lcd_brightness();
#Modify the brightness value
$grid_member->lcd_brightness(3);
```

lcd_hwident( )

Use this method to set or retrieve whether the grid member's hardware ID identification functionality is active.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the lcd_hwident flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the lcd_hwident status
my $lcd_hwident = $grid_member->lcd_hwident();
#Modify the lcd_hwident status
$grid_member->lcd_hwident("true");
```

lcd_version( )

Use this method to retrieve the version of the Liquid Crystal Display (LCD) of the appliance.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get lcd_version
my $lcd_version = $grid_member->lcd_version();
```

lom_gateway( )

Use this method to set or retrieve the gateway IP address of a grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lom_gateway
my $lom_gateway = $grid_member->lom_gateway();
#Modify lom_gateway
$grid_member->lom_gateway("3.0.0.1");
```

lom_ipv4addr( )

Use this method to set or retrieve the IPv4 address of a grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lom_ipv4addr
my $lom_ipv4addr = $grid_member->lom_ipv4addr();
#Modify lom_ipv4addr
$grid_member->lom_ipv4addr("3.0.0.3");
```

lom_is_capable( )

Use this method to retrieve a flag describing if a grid member is capable of the LOM functionality.

Parameter

The method returns "true" if the member is capable of LOM operation, "false" otherwise.

Returns

The method returns the attribute value.

Example

```
#Get lom_is_capable
my $lom_is_capable = $grid_member->lom_is_capable();
```

lom_mask( )

Use this method to set or retrieve the netmask of a grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Netmask address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.255.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lom_mask
my $lom_mask = $grid_member->lom_mask();
#Modify lom_mask
$grid_member->lom_mask("255.255.0.0");
```

lom_users( )

Use this method to set or retrieve the list of users for the LOM functionality.

Setting this method to a defined value implicitly sets the override_lom_users method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_lom_users attribute to "false".

Note that when lom_users is set to a defined value and override_dlom_users is set to "false", the last operation takes precedence. Thus the sequence $object->lom_users([$user1,$user2]); $object->override_lom_users("false"); will set override_lom_users to "false", and the sequence $object->override_lom_users("false"); $object->lom_users([$user1,$user2]); will result in override_lom_users="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::LOM::User objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lom_users from the member
my $users = $grid_member->lom_users();
#Modify the lom users
$grid_member->lom_users([$u1, $u2]);
```

mask( )

Use this method to set or retrieve the netmask of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Netmask address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.255.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mask
my $mask = $grid_member->mask();
#Modify mask
$grid_member->mask("255.255.0.0");
```

master_candidate( )

Use this method to set or retrieve the master_candidate flag of a grid member. This flag enables the grid member to assume the role of grid master as a disaster recovery measure.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the master_candidate flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get master candidate flag
my $master_candidate = $grid_member->master_candidate();
#Modify master candidate flag
$grid_member->master_candidate("true");
```

member_service_communication( )

Use this method to set or retrieve the communication type for various services.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::Member::Communication objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $attr = $grid_member->member_service_communication();
# Modify the attribute value
$grid_member->member_service_communication([$c1, $c2, $c3]);
```

mgmt_dscp( )

Use this method to set or retrieve the DSCP value of the IPv4 MGMT port.

Setting this method to a defined value implicitly sets the override_mgmt_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_mgmt_dscp attribute to "false".

Note that when dscp is set to a defined value and override_mgmt_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->mgmt_dscp(11); $object->override_mgmt_dscp("false"); will set override_mgmt_dscp to "false", and the sequence $object->override_mgmt_dscp("false"); $object->mgmt_dscp(11); will result in override_mgmt_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->mgmt_dscp();
#Modify attribute value
$grid_member->mgmt_dscp(11);
```

mgmt_gateway( )

Use this method to set or retrieve the gateway IP address of the MGMT port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mgmt gateway
my $mgmt_gateway = $grid_member->mgmt_gateway();
#Modify mgmt gateway
$grid_member->mgmt_gateway("4.0.0.1");
```

mgmt_lan( )

Use this method to set or retrieve the LAN IP address of the MGMT port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mgmt lan
my $mgmt_lan = $grid_member->mgmt_lan();
#Modify mgmt lan
$grid_member->mgmt_lan("4.0.0.2");
```

mgmt_ipv6addr( )

Use this method to set or retrieve the LAN IPv6 address of the MGMT port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get MGMT IPv6 address
my $mgmt_ipv6addr = $grid_member->mgmt_ipv6addr();
#Modify MGMT IPv6 address
$grid_member->mgmt_ipv6addr("2001::2");
```

mgmt_ipv6_cidr( )

Use this method to set or retrieve the CIDR of the MGMT port. Required only when mgmt_ipv6addr is specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the netmask in CIDR format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get MGMT cidr
my $mgmt_cidr = $grid_member->mgmt_cidr();
#Modify MGMT cidr
$grid_member->mgmt_cidr("64");
```

mgmt_ipv6_dscp( )

Use this method to set or retrieve the DSCP value of the IPv6 MGMT port.

Setting this method to a defined value implicitly sets the override_mgmt_ipv6_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_mgmt_ipv6_dscp attribute to "false".

Note that when dscp is set to a defined value and override_mgmt_ipv6_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->mgmt_ipv6_dscp(11); $object->override_mgmt_ipv6_dscp("false"); will set override_mgmt_ipv6_dscp to "false", and the sequence $object->override_mgmt_ipv6_dscp("false"); $object->mgmt_ipv6_dscp(11); will result in override_mgmt_ipv6_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->mgmt_ipv6_dscp();
#Modify attribute value
$grid_member->mgmt_ipv6_dscp(11);
```

mgmt_ipv6_enable_auto_config( )

Use this method to enable/disable IPv6 auto-configuration of the MGMT interface.

When IPv6 auto-configuration is enabled, a gateway is not needed since it will be automatically discovered.

Parameter

Specify "true" to enable IPv6 auto-configuration or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get IPv6 auto-configuration
my $ipv6_autoconfig_enabled = $grid_member->mgmt_ipv6_enable_auto_config();
#Modify IPv6 auto-configuration
$grid_member->mgmt_ipv6_enable_auto_config("true");
```

mgmt_ipv6_gateway( )

Use this method to set or retrieve the LAN IPv6 gateway of the MGMT port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get MGMT IPv6 gateway
my $mgmt_ipv6_gateway = $grid_member->mgmt_ipv6_gateway();
#Modify MGMT IPv6 gateway
$grid_member->mgmt_ipv6_gateway("2001::1");
```

mgmt_mask( )

Use this method to set or retrieve the netmask of the MGMT port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Netmask address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.255.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mgmt mask
my $mgmt_mask = $grid_member->mgmt_mask();
#Modify mgmt mask
$grid_member->mgmt_mask("255.255.0.0");
```

mgmt_node2_port_duplex( )

Use this method to specify the duplex setting of the MGMT port on node 2 of an HA pair. Note: Use this method in combination with mgmt_node2_port_speed. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are "Half" or "Full". The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mgmt_node2_port_duplex
my $mgmt_node2_port_duplex = $obj->mgmt_node2_port_duplex();
#Modify mgmt_node2_port_duplex
$obj->mgmt_node2_port_duplex("Half");
```

mgmt_node2_port_speed( )

Use this method to set the connection speed of the MGMT port on node 2 of an HA pair. Note: Use this method in combination with mgmt_node2_port_duplex. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are 10, 100 or 1000. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mgmt_node2_port_speed
my $mgmt_node2_port_speed = $obj->mgmt_node2_port_speed();
#Modify mgmt_node2_port_speed
```

```
$obj->mgmt_node2_port_speed(10);
```

mgmt_port( )

Use this method to set or retrieve the MGMT port flag of a grid member. You can restrict administrative access to an Infoblox appliance by connecting the MGMT port to a subnet containing only management systems.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that node1_mgmt_port, node2_mgmt_port and mgmt_port share the value; setting any of them will have the same effect.

Parameter

Specify "true" to set the mgmt_port flag or "false" to deactivate/unset it. The default value is "false". To disable the mgmt_port flag, you must disable the "node1_mgmt_port" and "node2_mgmt_port" flags as well.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get MGMT port flag
my $mgmt_port = $grid_member->mgmt_port();
#Modify MGMT port flag
$grid_member->mgmt_port("true");
```

mgmt_port_duplex( )

Use this method to specify the duplex setting of the MGMT port on a single grid member or on node 1 of an HA grid member. Note: Use this method in combination with mgmt_port_speed. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are "Half" or "Full". The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mgmt_port_duplex
my $mgmt_port_duplex = $obj->mgmt_port_duplex();
#Modify mgmt_port_duplex
$obj->mgmt_port_duplex("Half");
```

mgmt_port_speed( )

Use this method to specify the connection speed of the MGMT port on a single grid member or on node 1 of an HA grid member. Note: Use this method in combination with mgmt_port_duplex. If any of these attributes are undefined, the default values for duplex and speed settings are used.

Parameter

Valid values are 10, 100 or 1000. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mgmt_port_speed
my $mgmt_port_speed = $obj->mgmt_port_speed();
#Modify mgmt_port_speed
$obj->mgmt_port_speed(10);
```

mgmt_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the MGMT port on a single grid member or on node 1 of an HA grid

member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->mgmt_reserved_interface();
#Modify attribute value
$grid_member->mgmt_reserved_interface($interface);
```

mmdb_ea_build_time( )

Use this method to retrieve the extensible attributes MaxMind database build time. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1, 1970 UTC.

Example

```
#Get mmdb_ea_build_time value
my $value = $object->mmdb_ea_build_time();
```

mmdb_geoip_build_time( )

Use this method to retrieve the GeoIP MaxMind database build time. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1, 1970 UTC.

Example

```
#Get mmdb_ea_build_time value
my $value = $object->mmdb_ea_build_time();
```

name( )

Use this method to set or retrieve the host name of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The host name in FQDN (Fully Qualified Domain Name) format of a grid member. The FQDN consists of the host name followed by the domain name (example: abc.com). A host name can have a maximum of 256 bytes.

Note that name matching is not case-sensitive, and that names are inserted in lowercase.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $grid_member->name();
#Modify name
$grid_member->name("hostname2.com");
```

nat_enabled( )

Use this method to set or retrieve the NAT compatibility setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the NAT compatibility setting or "false" to disable it.

This method will also be automatically set to "true" or "false" when "nat_group", "nat_ip_address", "node1_nat" and "node2_nat" change. If any of them is set, nat_enabled will be set to "true"; if all of them are undefined, it will be set to "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nat group
my $nat_group = $grid_member->nat_group();
#Modify nat group
$grid_member->nat_group("nat_group");
```

nat_group( )

Use this method to set or retrieve the NAT group of a grid member. Required only when NAT compatibility is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Text with the NAT (Network Address Translation) group name with a maximum of 256 bytes. Default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nat group
my $nat_group = $grid_member->nat_group();
#Modify nat group
$grid_member->nat_group("nat_group");
```

nat_ip_address( )

Use this method to set or retrieve the NAT IP address of a grid member. Required only when NAT compatibility is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nat IP address
my $nat_ip_address = $grid_member->nat_ip_address();
#Modify nat ip address
$grid_member->nat_ip_address("5.5.5.5");
```

nic_failover_enabled( )

Use this method to set or retrieve the nic_failover_enabled flag of a grid member. This is required only when the member is a single appliance. To enable this flag, the lan2_port flag must also be set to 'true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the nic_failover_enabled flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get NIC failover enabled flag
my $nic_failover_enabled = $grid_member->nic_failover_enabled();
#Modify NIC failover enabled flag
$grid_member->nic_failover_enabled("true");
```

nic_failover_enable_primary( )

Use this method to set or retrieve the flag that indicates whether to prefer LAN1 when it's available or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to nic_failover_enable_primary flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nic_failover_enable_primary value
my $value = $object->nic_failover_enable_primary();

#Modify nic_failover_enable_primary value
$object->nic_failover_enable_primary("true");
```

node1_ha( )

Use this method to set or retrieve the HA IP address of node 1. Required only when the member is an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node1 ha IP address
my $node1_ha = $grid_member->node1_ha();
#Modify node1 ha IP address
$grid_member->node1_ha("3.0.0.4");
```

node1_ha_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the HA port on node 1 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->node1_ha_reserved_interface();
#Modify attribute value
$grid_member->node1_ha_reserved_interface($interface);
```

node1_paid_nios( )

Use this method to retrieve whether the node 1 of an HA grid member is Paid NIOS.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get Paid NIOS status
my $node1_paid_nios = $grid_member->node1_paid_nios();
```

node1_hwplatform( )

Use this method to retrieve the hardware platform of node 1 of an HA grid member.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get hardware platform
my $node1_hwplatform = $grid_member->node1_hwplatform();
```

node1_hwid( )

Use this method to retrieve the hardware ID of node 1 of an HA grid member.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get node1 hardware ID
my $node1_hwid = $grid_member->node1_hwid();
```

node1_lan( )

Use this method to set or retrieve the LAN IPv4 address of node 1 of an HA grid member. Required only when the member is an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN IP address of node1
my $node1_lan = $grid_member->node1_lan();
#Modify LAN IP address of node1
$grid_member->node1_lan("3.0.0.9");
```

node1_lan_ipv6addr( )

Use this method to set or retrieve the LAN IPv6 address of node 1 of an HA grid member. Required only when the member is an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN IPv6 address of node1
my $node1_lan_ipv6addr = $grid_member->node1_lan_ipv6addr();
#Modify LAN IPv6 address of node1
$grid_member->node1_lan_ipv6addr("2001::1");
```

node1_lan_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the LAN port on node 1 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->node1_lan_reserved_interface();
#Modify attribute value
$grid_member->node1_lan_reserved_interface($interface);
```

node1_lan2_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the LAN2 port on node 1 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->node1_lan2_reserved_interface();
#Modify attribute value
$grid_member->node1_lan2_reserved_interface($interface);
```

node1_lcd_autodim( )

Use this method to set or retrieve the number of seconds before the LCD on the front panel of node 1 of an HA grid member automatically dims.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of seconds. Valid values are between 5 and 3600. The default value is 30.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lcd_autodim on node 1
my $node1_lcd_autodim = $grid_member->node1_lcd_autodim();
#Modify the autodim value
$grid_member->node1_lcd_autodim(60);
```

node1_lcd_brightness( )

Use this method to set or retrieve the brightness level of the LCD on the front panel of node 1 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are between 1 and 10. The default value is 7.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lcd_brightness on node 1
my $node1_lcd_brightness = $grid_member->node1_lcd_brightness();
#Modify the brightness value
$grid_member->node1_lcd_brightness(3);
```

node1_lcd_hwident( )

Use this method to set or retrieve whether the node 1 of an HA grid member's hardware ID identification functionality is active.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the lcd_hwident flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the lcd_hwident status
my $node1_lcd_hwident = $grid_member->node1_lcd_hwident();
#Modify the lcd_hwident status
$grid_member->node1_lcd_hwident("true");
```

node1_lcd_version( )

Use this method to retrieve the version of the Liquid Crystal Display (LCD) of the node 1 of an HA grid member.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get node1_lcd_version
my $node1_lcd_version = $grid_member->node1_lcd_version();
```

node1_lom_gateway( )

Use this method to set or retrieve the gateway IP address on node 1 of an HA grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node1_lom_gateway
my $node1_lom_gateway = $grid_member->node1_lom_gateway();
#Modify node1_lom_gateway
$grid_member->node1_lom_gateway("3.0.0.1");
```

node1_lom_is_capable( )

Use this method to retrieve a flag describing if node 1 of an HA grid member is capable of the LOM functionality.

Parameter

The method returns "true" if the node is capable of LOM operation, "false" otherwise.

Returns

The method returns the attribute value.

Example

```
#Get node1_lom_is_capable
my $node1_lom_is_capable = $grid_member->node1_lom_is_capable();
```

node1_lom_ipv4addr( )

Use this method to set or retrieve the IPv4 address on node 1 of an HA grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node1_lom_ipv4addr
my $node1_lom_ipv4addr = $grid_member->node1_lom_ipv4addr();
#Modify node1_lom_ipv4addr
$grid_member->node1_lom_ipv4addr("3.0.0.3");
```

node1_lom_mask( )

Use this method to set or retrieve the netmask on node 1 of an HA grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Netmask address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.255.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node1_lom_mask
my $node1_lom_mask = $grid_member->node1_lom_mask();
#Modify node1_lom_mask
$grid_member->node1_lom_mask("255.255.0.0");
```

node1_mgmt_dscp( )

Use this method to set or retrieve the DSCP value of the IPv4 MGMT port on node 1 of an HA grid member.

Setting this method to a defined value implicitly sets the override_node1_mgmt_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_node1_mgmt_dscp attribute to "false".

Note that when dscp is set to a defined value and override_node1_mgmt_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->node1_mgmt_dscp(11); $object->override_node1_mgmt_dscp("false"); will set override_node1_mgmt_dscp to "false", and the sequence $object->override_node1_mgmt_dscp("false"); $object->node1_mgmt_dscp(11); will result in override_node1_mgmt_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->node1_mgmt_dscp();
#Modify attribute value
$grid_member->node1_mgmt_dscp(11);
```

node1_mgmt_gateway( )

Use this method to set or retrieve the gateway IP address of the MGMT port on node 1 of an HA grid member. Required only when the MGMT port is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get gateway of MGMT port of node1
my $node1_mgmt_gateway = $grid_member->node1_mgmt_gateway();
#Modify gateway of MGMT port of node1
$grid_member->node1_mgmt_gateway("6.0.0.1");
```

node1_mgmt_ipv6addr( )

Use this method to set or retrieve the LAN IPv6 address of the MGMT port on node 1 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get MGMT IPv6 address of node 1
my $node1_mgmt_ipv6addr = $grid_member->node1_mgmt_ipv6addr();
#Modify MGMT IPv6 address of node 1
$grid_member->node1_mgmt_ipv6addr("2001::2");
```

node1_mgmt_ipv6_cidr( )

Use this method to set or retrieve the CIDR of the MGMT port on node 1 of an HA grid member. Required only when node1_mgmt_ipv6addr is specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the netmask in CIDR format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get MGMT cidr of node 1
my $node1_mgmt_cidr = $grid_member->node1_mgmt_cidr();
#Modify MGMT cidr of node 1
$grid_member->node1_mgmt_cidr("64");
```

node1_mgmt_ipv6_dscp( )

Use this method to set or retrieve the DSCP value of the IPv6 MGMT port on node 1 of an HA grid member.

Setting this method to a defined value implicitly sets the override_node1_mgmt_ipv6_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_node1_mgmt_ipv6_dscp attribute to "false".

Note that when dscp is set to a defined value and override_node1_mgmt_ipv6_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->node1_mgmt_ipv6_dscp(11); $object->override_node1_mgmt_ipv6_dscp("false"); will set override_node1_mgmt_ipv6_dscp to "false", and the sequence $object->override_node1_mgmt_ipv6_dscp("false"); $object->node1_mgmt_ipv6_dscp(11); will result in override_node1_mgmt_ipv6_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->node1_mgmt_ipv6_dscp();
#Modify attribute value
$grid_member->node1_mgmt_ipv6_dscp(11);
```

node1_mgmt_ipv6_enable_auto_config( )

Use this method to enable/disable IPv6 auto-configuration of the MGMT interface.

When IPv6 auto-configuration is enabled, a gateway is not needed since it will be automatically discovered.

Parameter

Specify "true" to enable IPv6 auto-configuration or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get IPv6 auto-configuration of node 1
my $ipv6_autoconfig_enabled = $grid_member->node1_mgmt_ipv6_enable_auto_config();
#Modify IPv6 auto-configuration of node 1
$grid_member->node1_mgmt_ipv6_enable_auto_config("true");
```

node1_mgmt_ipv6_gateway( )

Use this method to set or retrieve the LAN IPv6 gateway of the MGMT port on node 1 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get MGMT IPv6 gateway of node 1
my $node1_mgmt_ipv6_gateway = $grid_member->node1_mgmt_ipv6_gateway();
#Modify MGMT IPv6 gateway of node 1
$grid_member->node1_mgmt_ipv6_gateway("2001::1");
```

node1_mgmt_mask( )

Use this method to set or retrieve the netmask of the MGMT port on node 1 of an HA grid member. Required only when the MGMT port is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Netmask address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.255.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get netmask of MGMT port of node 1
my $node1_mgmt_mask = $grid_member->node1_mgmt_mask();
#Modify netmask of MGMT port of node 1
$grid_member->node1_mgmt_mask("255.255.0.0");
```

node1_mgmt_lan( )

Use this method to set or retrieve the LAN IP address of the MGMT port on node 1 of an HA grid member. Required only when the MGMT port is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN IP address of MGMT port on node 1
my $node1_mgmt_lan = $grid_member->node1_mgmt_lan();
#Modify LAN IP address of MGMT port on node 1
$grid_member->node1_mgmt_lan("6.0.0.5");
```

node1_mgmt_port( )

Use this method to set or retrieve the MGMT port flag of an HA grid member. Required only when the MGMT port is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that node1_mgmt_port, node2_mgmt_port and mgmt_port share the value; setting any of them will have the same effect.

Parameter

Specify "true" to set the node1_mgmt_port flag or "false" to deactivate/unset it. The default value is undefined. To disable node1_mgmt_port flag we also need to disable "mgmt_port" and "node2_mgmt_port" flags.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node 1 MGMT port flag
my $node1_mgmt_port = $grid_member->node1_mgmt_port();
#Modify node 1 MGMT port flag
$grid_member->node1_mgmt_port("true");
```

node1_mgmt_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the MGMT port on node 1 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->node1_mgmt_reserved_interface();
#Modify attribute value
$grid_member->node1_mgmt_reserved_interface($interface);
```

node1_nat( )

Use this method to set or retrieve the Network Address Translation (NAT) address of node 1 of an HA grid member. Required only when NAT compatibility is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get Network Address Translation (NAT) address of node 1
my $node1_nat = $grid_member->node1_nat();
#Modify Network Address Translation (NAT) address of node 1
$grid_member->node1_nat("5.2.2.1");
```

node1_service_status( )

Use this method to retrieve the service status list of a grid member.

Returns

On retrieval, the member returns an array reference that contains Infoblox::Grid::Member::ServiceStatus objects.

Example

```
#Get the service status list
my $services_list = $grid_member->node1_service_status();
```

vpn_mtu( )

Use this method to set or retrieve the VPN maximum transmission unit (MTU).

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the value to set the vpn_mtu value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get VPN MTU
my $vpn_mtu = $grid_member->vpn_mtu();
#Modify VPN MTU
$grid_member->vpn_mtu(600);
```

node1_vpn_on_mgmt( )

Use this method to set or retrieve the VPN on MGMT port flag of an HA grid member. Valid only when the MGMT port is enabled and the member is not a master candidate. This flag enables VPN services on the MGMT port of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that node1_vpn_on_mgmt, node2_vpn_on_mgmt and vpn_on_mgmt share the value; setting any of them will have the same effect.

Parameter

Specify "true" to set the node1_vpn_on_mgmt flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node 1 VPN on MGMT port flag
my $node1_vpn_on_mgmt = $grid_member->node1_vpn_on_mgmt();
#Modify node 1 VPN on MGMT port flag
$grid_member->node1_vpn_on_mgmt("false");
```

node1_hwtype( )

Use this method to retrieve the hardware type of node 1 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The actual hardware type is populated when the physical node joins the grid. The default value is "".

Returns

The method returns the attribute value.

Example

```
#Get node1 hardware type
```

```
my $node1_hwtype = $grid_member->node1_hwtype();
```

node2_ha( )

Use this method to set or retrieve the HA IP address of node 2 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node 2 HA IP address
my $node2_ha = $grid_member->node2_ha();
#Modify node 2 HA IP address
$grid_member->node2_ha("3.0.0.6");
```

node2_ha_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the HA port on node 2 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->node2_ha_reserved_interface();
#Modify attribute value
$grid_member->node2_ha_reserved_interface($interface);
```

node2_paid_nios( )

Use this method to retrieve whether the node 2 of an HA grid member is Paid NIOS.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get Paid NIOS status
my $node2_paid_nios = $grid_member->node2_paid_nios();
```

node2_hwplatform( )

Use this method to retrieve the hardware platform of node 2 of an HA grid member.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get hardware platform
my $node2_hwplatform = $grid_member->node2_hwplatform();
```

node2_hwid( )

Use this method to retrieve the hardware ID of node 2 of an HA grid member.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get node2 hardware ID
my $node2_hwid = $grid_member->node2_hwid();
```

node2_lan( )

Use this method to set or retrieve the LAN IP address of node 2 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN IP address of node 2
my $node2_lan = $grid_member->node2_lan();
#Modify LAN IP address of node 2
$grid_member->node2_lan("3.0.0.5");
```

node2_lan_ipv6addr( )

Use this method to set or retrieve the LAN IPv6 address of node 2 of an HA grid member. Required only when the member is an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN IPv6 address of node2
my $node2_lan_ipv6addr = $grid_member->node2_lan_ipv6addr();
#Modify LAN IPv6 address of node2
$grid_member->node2_lan_ipv6addr("2001::1");
```

node2_lan_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the LAN port on node 2 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->node2_lan_reserved_interface();
#Modify attribute value
$grid_member->node2_lan_reserved_interface($interface);
```

node2_lan2_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the LAN2 port on node 2 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->node2_lan2_reserved_interface();
#Modify attribute value
$grid_member->node2_lan2_reserved_interface($interface);
```

node2_lcd_autodim( )

Use this method to set or retrieve the number of seconds before the LCD on the front panel of node 2 of an HA grid member automatically dims.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of seconds. Valid values are between 5 and 3600. The default value is 30.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lcd_autodim on node 2
my $node2_lcd_autodim = $grid_member->node2_lcd_autodim();
#Modify the autodim value
$grid_member->node2_lcd_autodim(60);
```

node2_lcd_brightness( )

Use this method to set or retrieve the brightness level of the LCD on the front panel of node 2 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are between 1 and 10. The default value is 7.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lcd_brightness on node 2
my $node2_lcd_brightness = $grid_member->node2_lcd_brightness();
#Modify the brightness value
$grid_member->node2_lcd_brightness(3);
```

node2_lcd_hwident( )

Use this method to set or retrieve whether the node 2 of an HA grid member's hardware ID identification functionality is active.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the node2_lcd_hwident flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the lcd_hwident status
my $node2_lcd_hwident = $grid_member->node2_lcd_hwident();
#Modify the lcd_hwident status
$grid_member->node2_lcd_hwident("true");
```

node2_lcd_version( )

Use this method to retrieve the version of the Liquid Crystal Display (LCD) of the node 2 of an HA grid member.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get node2_lcd_version
my $node2_lcd_version = $grid_member->node2_lcd_version();
```

node2_lom_gateway( )

Use this method to set or retrieve the gateway IP address on node 2 of an HA grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node2_lom_gateway
my $node2_lom_gateway = $grid_member->node2_lom_gateway();
#Modify node2_lom_gateway
$grid_member->node2_lom_gateway("3.0.0.1");
```

node2_lom_is_capable( )

Use this method to retrieve a flag describing if node 1 of an HA grid member is capable of the LOM functionality.

Parameter

The method returns "true" if the node is capable of LOM operation, "false" otherwise.

Returns

The method returns the attribute value.

Example

```
#Get node2 lom is capable
```

```
my $node2_lom_is_capable = $grid_member->node2_lom_is_capable();
```

node2_lom_ipv4addr( )

Use this method to set or retrieve the IPv4 address on node 2 of an HA grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node2_lom_ipv4addr
my $node2_lom_ipv4addr = $grid_member->node2_lom_ipv4addr();
#Modify node2_lom_ipv4addr
$grid_member->node2_lom_ipv4addr("3.0.0.3");
```

node2_lom_mask( )

Use this method to set or retrieve the netmask on node 2 of an HA grid member for the LOM functionality.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Netmask address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.255.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node2_lom_mask
my $node2_lom_mask = $grid_member->node2_lom_mask();
#Modify node2_lom_mask
$grid_member->node2_lom_mask("255.255.0.0");
```

node2_mgmt_dscp( )

Use this method to set or retrieve the DSCP value of the IPv4 MGMT port on node 2 of an HA grid member.

Setting this method to a defined value implicitly sets the override_node2_mgmt_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_node2_mgmt_dscp attribute to "false".

Note that when dscp is set to a defined value and override_node2_mgmt_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->node2_mgmt_dscp(11); $object->override_node2_mgmt_dscp("false"); will set override_node2_mgmt_dscp to "false", and the sequence $object->override_node2_mgmt_dscp("false"); $object->node2_mgmt_dscp(11); will result in override_node2_mgmt_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->node2_mgmt_dscp();
#Modify attribute value
```

```
$grid_member->node2_mgmt_dscp(11);
```

node2_mgmt_gateway( )

Use this method to set or retrieve the gateway IP address of the MGMT port on node 2 of an HA grid member. Required only when the MGMT port is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get gateway of MGMT port of node 2
my $node2_mgmt_gateway = $grid_member->node2_mgmt_gateway();
#Modify gateway of MGMT port of node 2
$grid_member->node2_mgmt_gateway("7.0.0.1");
```

node2_mgmt_mask( )

Use this method to set or retrieve the netmask of the MGMT port on node 2 of an HA grid member. Required only when the MGMT port is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Netmask address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.255.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get netmask of MGMT port of node 2
my $node2_mgmt_mask = $grid_member->node2_mgmt_mask();
#Modify netmask of MGMT port of node 2
$grid_member->node2_mgmt_mask("255.255.0.0");
```

node2_mgmt_lan( )

Use this method to set or retrieve the LAN IP address of the MGMT port on node 2 of an HA grid member. Required only when the MGMT port is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get LAN IP address of MGMT port of node 2
my $node2_mgmt_lan = $grid_member->node2_mgmt_lan();
#Modify LAN IP address of MGMT port of node 2
$grid_member->node2_mgmt_lan("7.0.0.5");
```

node2_mgmt_port( )

Use this method to set or retrieve the MGMT port flag of an HA grid member. Required only when the MGMT port is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that node1_mgmt_port, node2_mgmt_port and mgmt_port share the value: setting any of them will have the same effect.

Parameter

Specify "true" to set the node2_mgmt_port flag or "false" to deactivate/unset it. The default value is undefined. To disable node2_mgmt_port flag, you must disable the "mgmt_port" and "node1_mgmt_port" flags as well.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get MGMT port flag of node 2
my $node2_mgmt_port = $grid_member->node2_mgmt_port();
#Modify MGMT port flag of node 2
$grid_member->node2_mgmt_port("true");
```

node2_mgmt_reserved_interface( )

Use this method to set or retrieve the discovery reserved interface of the MGMT port on node 2 of an HA grid member.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->node2_mgmt_reserved_interface();
#Modify attribute value
$grid_member->node2_mgmt_reserved_interface($interface);
```

node2_mgmt_ipv6_dscp( )

Use this method to set or retrieve the DSCP value of the IPv6 MGMT port on node 2 of an HA grid member.

Setting this method to a defined value implicitly sets the override_node2_mgmt_ipv6_dscp method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_node2_mgmt_ipv6_dscp attribute to "false".

Note that when dscp is set to a defined value and override_node2_mgmt_ipv6_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->node2_mgmt_ipv6_dscp(11); $object->override_node2_mgmt_ipv6_dscp("false"); will set override_node2_mgmt_ipv6_dscp to "false", and the sequence $object->override_node2_mgmt_ipv6_dscp("false"); $object->node2_mgmt_ipv6_dscp(11); will result in override_node2_mgmt_ipv6_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $grid_member->node2_mgmt_ipv6_dscp();
#Modify attribute value
$grid_member->node2_mgmt_ipv6_dscp(11);
```

node2_nat( )

Use this method to set or retrieve the Network Address Translation (NAT) address of node 2. Required only when NAT compatibility is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get Network Address Translation (NAT) address of node2
my $node2_nat = $grid_member->node2_nat();
#Modify Network Address Translation (NAT) address of node2
$grid_member->node2_nat("5.4.4.6");
```

node2_service_status( )

Use this method to retrieve the service status list of a grid member.

Returns

On retrieval, the member returns an array reference that contains Infoblox::Grid::Member::ServiceStatus objects.

Example

```
#Get the service status list
my $services_list = $grid_member->node2_service_status();
```

node2_vpn_on_mgmt( )

Use this method to set or retrieve the VPN on MGMT port flag of an HA grid member. Valid only when the MGMT port is enabled and the member is not a master candidate. This flag enables VPN services on the MGMT port of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that node1_vpn_on_mgmt, node2_vpn_on_mgmt and vpn_on_mgmt share the value: setting any of them will have the same effect.

Parameter

Specify "true" to set the node2_vpn_on_mgmt flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get node 2 VPN on MGMT port flag
my $node2_vpn_on_mgmt = $grid_member->node2_vpn_on_mgmt();
#Modify node 2 VPN on MGMT port flag
$grid_member->node2_vpn_on_mgmt("false");
```

node2_hwtype( )

Use this method to retrieve the hardware type of node 2 of an HA grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The actual hardware type is populated when the physical node joins the grid. The default value is "".

Returns

The method returns the attribute value.

Example

```
#Get node2 hardware type
```

```
my $node2_hwtype = $grid_member->node2_hwtype();
```

notification_email_addr( )

Use this method to set or retrieve the notification email address of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The email address. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get notification email address
my $notification_email_addr = $grid_member->notification_email_addr();
#Modify notification email address
$grid_member->notification_email_addr("admin\@infoblox.com");
```

ntp_access_list( )

Use this method to set or retrieve the Network Time Protocols (NTP) access control list of a grid member. Valid only when the enable_ntp flag is set to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains Infoblox::Grid::NTPAccess objects .

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get NTP access control list
my $ntp_access_list = $grid_member->ntp_access_list();
#Modify NTP access control list
$grid_member->ntp_access_list([$ntpac1,$ntpac2]);
#Undef NTP access control list
$grid_member->ntp_access_list(undef);
#Use Infoblox::Grid::NamedACL
$grid_member->ntp_access_list($nacl);
```

---

ntp_kod( )

Use this method to enable Kiss-o'-Death packets on the NTP server.

Setting this method to a defined value implicitly sets the override_ntp_kod method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ntp_kod attribute to "false".

Note that when ntp_kod is set to a defined value and override_ntp_kod is set to "false", the last operation takes precedence. Thus the sequence $object->ntp_kod("true"); $object->override_ntp_kod("false"); will set override_ntp_kod to "false", and the sequence $object->override_ntp_kod("false"); $object->ntp_kod("true"); will result in override_ntp_kod="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable Kiss-o'-Death packets on the NTP server or "false" to disable them. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the current value of the ntp_kod parameter
my $ntp_kod = $grid->ntp_kod();
#Set the ntp_kod parameter
$grid->ntp_kod("true");
```

ntp_service_type( )

Use this method to set or retrieve the NTP service type for assigned Named ACL object.

The attribute value is ignored if 'ntp_access_list' attribute is not a Named ACL object.

Parameter

Valid values are "Time" or "Time and NTP control". The default value is "Time".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ntp_service_type
my $service = $grid_member->ntp_service_type();
#Modify ntp_service_type
$grid_member->ntp_service_type("Time and NTP control");
```

ntp_authentication_key( )

Use this method to set or retrieve the Network Time Protocol (NTP) authentication `key(s)` of a grid member. Valid only when the enable_ntp flag is set to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::NTPKey object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get NTP authentication key
my $ntp_authentication_key = $grid_member->ntp_authentication_key();
#Modify NTP authentication key
my $ntp_key1 = Infoblox::Grid::NTPKey->new(
    key_number => "1111",
    key_type   => "M",
    key_string => "aaaa"
);
my $ntp_key2 = Infoblox::Grid::NTPKey->new(
    key_number => "2222",
    key_type   => "n",
    key_string => "d3e54352e5548080"
);
$grid_member->ntp_authentication_key([$ntp_key1, $ntp_key2]);
```

ntp_server( )

Use this method to set or retrieve the NTP server list.

Parameter

Array reference that contains Infoblox::Grid::NTPServer objects or undef.

Specifying a reference to an empty array while the "exclude_grid_master_as_ntp_server" attribute is set to "false" sets the Grid Master as the only NTP source for the given Member. Setting the value of this parameter to undef disables the feature.

NOTE: Currently, if you need to specify an external NTP server with authentication, the NTP keys that you use must be known to the Infoblox::Grid object. See the following example.

NOTE: Setting this to a list also sets external_ntp_servers_enabled to 'true'. Setting this to undef also sets external_ntp_servers_enabled to 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get the ntp_server list for the given member
my $ntp_server_list=$grid_member->ntp_server();

#Modify ntp_server property
my $ntp_server1 = Infoblox::Grid::NTPServer->new(address => "1.1.1.1");
my $ntp_server2 = Infoblox::Grid::NTPServer->new(address => "2.2.2.2");
$grid_member->ntp_server([$ntp_server1,$ntp_server2]);

#Setting grid master as the only NTP source
my $session=Infoblox::Session->new(
    master   => "127.0.0.1",
    username => "admin",
    password => "infoblox"
   );
die(Infoblox::status_code().":".Infoblox::status_detail()) unless $session;

my $grid_member=$session->get(
                              object => "Infoblox::Grid::Member",
                              name   => "infoblox.localdomain"
                             );
die($session->status_code()." : ".$session->status_detail()) unless (ref($grid_member) eq
"Infoblox::Grid::Member");

$grid_member->ntp_server([]);
$grid_member->exclude_grid_master_as_ntp_server("false");
$session->modify($grid_member) or die($session->status_code()." : ".$session->status_detail());

#Adding external NTP servers with authentication
my $session=Infoblox::Session->new(
    master   => "127.0.0.1",
    username => "admin",
    password => "infoblox"
   );
die(Infoblox::status_code().":".Infoblox::status_detail()) unless $session;
my $grid_member=$session->get(
                              object => "Infoblox::Grid::Member",
                              name   => "infoblox.localdomain"
                             );
die($session->status_code()." : ".$session->status_detail()) unless (ref($grid_member) eq
"Infoblox::Grid::Member");

my $grid=$session->get(
                        object => "Infoblox::Grid",
                        name   => "Infoblox"
                      );
die($session->status_code()." : ".$session->status_detail()) unless (ref($grid) eq
"Infoblox::Grid");

#It is assumed in the following that the grid has NTP enabled
die("Grid must have ntp enabled) unless ($grid->enable_ntp() eq "true");

my $ntp_key_1= Infoblox::Grid::NTPKey->new(
           key_number => "101",
           key_type   => "n",
           key_string => "d3e54352e5548080"
       );
$grid->ntp_authentication_key([$ntp_key_1]);
$session->modify($grid) or die(($session->status_code()." : ".$session->status_detail());

my $ntp_server=Infoblox::Grid::NTPServer->new(
                                              address => "1.1.1.1"
                                              authentication => "true"
                                              ntp_key=>$ntp_key_1
                                             );

$grid_member->ntp_server([$ntp_server]);
$session->modify($grid_member) or die(($session->status_code()." : ".$session->status_detail());
```

ospf_list( )

Use this method to set or retrieve the OSPF area configuration (for anycast) list of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Member::OSPF object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get OSPF list
my $ospf_list = $grid_member->ospf_list();
#Modify OSPF list
my $ospf1 = Infoblox::Grid::Member::OSPF->new(
        area_id             => "1",
        interface           => "LAN_HA",
        authentication_type => "none",
);

$grid_member->ospf_list([$ospf1]);
```

override_enable_lom( )

The override_enable_lom attribute controls whether the enable_lom value in the member is used, instead of the grid default.

The override_enable_lom attribute can be specified explicitly. It is also set implicitly when enable_lom is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_enable_lom flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_lom from the member
my $override = $grid_member->override_enable_lom();
#Modify override_enable_lom
$grid_member->override_enable_lom("true");
```

override_lom_users( )

The override_lom_users attribute controls whether the lom_users value in the member is used, instead of the grid default.

The override_lom_users attribute can be specified explicitly. It is also set implicitly when lom_users is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_lom_users flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_lom_users from the member
my $override = $grid_member->override_lom_users();
#Modify lom_users
$grid_member->override_lom_users("true");
```

override_dscp( )

The override_dscp attribute contols whether the member DSCP value is used, instead of the Grid default.

The override_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_dscp from the member
my $override = $grid_member->override_dscp();
#Modify override_dscp
$grid_member->override_dscp("true");
```

override_enable_member_redirect( )

The override_enable_member_redirect attribute controls whether the enable_member_redirect value in the member is used, instead of the grid default.

The override_enable_member_redirect attribute can be specified explicitly. It is also set implicitly when enable_member_redirect is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_enable_member_redirect flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_member_redirect from the member
my $override = $grid_member->override_enable_member_redirect();
#Modify enable_member_redirect
$grid_member->override_enable_member_redirect("true");
```

override_lan1_dscp( )

The override_lan1_dscp attribute contols whether the DSCP value of the IPv4 LAN1 port is used, instead of the Grid default.

The override_lan1_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_lan1_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_lan1_dscp from the member
my $override = $grid_member->override_lan1_dscp();
#Modify override_lan1_dscp
$grid_member->override_lan1_dscp("true");
```

override_lan1_ipv6_dscp( )

The override_lan1_ipv6_dscp attribute contols whether the DSCP value of the IPv6 LAN1 port is used, instead of the Grid default.

The override_lan1_ipv6_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_lan1_ipv6_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_lan1_ipv6_dscp from the member
my $override = $grid_member->override_lan1_ipv6_dscp();
#Modify override_lan1_ipv6_dscp
$grid_member->override_lan1_ipv6_dscp("true");
```

override_lan2_dscp( )

The override_lan2_dscp attribute contols whether the DSCP value of the IPv4 LAN2 port is used, instead of the Grid default.

The override_lan2_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_lan2_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_lan2_dscp from the member
my $override = $grid_member->override_lan2_dscp();
#Modify override_lan2_dscp
$grid_member->override_lan2_dscp("true");
```

override_lan2_ipv6_dscp( )

The override_lan2_ipv6_dscp attribute contols whether the DSCP value of the IPv6 LAN2 port is used, instead of the Grid default.

The override_lan2_ipv6_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_lan2_ipv6_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_lan2_ipv6_dscp from the member
my $override = $grid_member->override_lan2_ipv6_dscp();
#Modify override_lan2_ipv6_dscp
$grid_member->override_lan2_ipv6_dscp("true");
```

override_mgmt_dscp( )

The override_mgmt_dscp attribute contols whether the DSCP value of the IPv4 MGMT port is used, instead of the Grid default.

The override_mgmt_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_mgmt_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_mgmt_dscp from the member
my $override = $grid_member->override_mgmt_dscp();
#Modify override_mgmt_dscp
$grid_member->override_mgmt_dscp("true");
```

override_mgmt_ipv6_dscp( )

The override_mgmt_ipv6_dscp attribute contols whether the DSCP value of the IPv6 MGMT port is used, instead of the Grid default.

The override_mgmt_ipv6_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_mgmt_ipv6_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_mgmt_ipv6_dscp from the member
my $override = $grid_member->override_mgmt_ipv6_dscp();
#Modify override_mgmt_ipv6_dscp
$grid_member->override_mgmt_ipv6_dscp("true");
```

override_node1_mgmt_dscp( )

The override_node1_mgmt_dscp attribute contols whether the DSCP value of the IPv4 MGMT port on node 1 of an HA grid member is used, instead of the Grid default.

The override_node1_mgmt_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_node1_mgmt_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_node1_mgmt_dscp from the member
my $override = $grid_member->override_node1_mgmt_dscp();
#Modify override_node1_mgmt_dscp
$grid_member->override_node1_mgmt_dscp("true");
```

override_node1_mgmt_ipv6_dscp( )

The override_node1_mgmt_ipv6_dscp attribute contols whether the DSCP value of the IPv6 MGMT port on node 1 of an HA grid member is used, instead of the Grid default.

The override_node1_mgmt_ipv6_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_node1_mgmt_ipv6_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_node1_mgmt_ipv6_dscp from the member
my $override = $grid_member->override_node1_mgmt_ipv6_dscp();
#Modify override_node1_mgmt_ipv6_dscp
$grid_member->override_node1_mgmt_ipv6_dscp("true");
```

override_node2_mgmt_dscp( )

The override_node2_mgmt_dscp attribute contols whether the DSCP value of the IPv4 MGMT port on node 2 of an HA grid member is used, instead of the Grid default.

The override_node2_mgmt_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_node2_mgmt_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_node2_mgmt_dscp from the member
my $override = $grid_member->override_node2_mgmt_dscp();
#Modify override_node2_mgmt_dscp
$grid_member->override_node2_mgmt_dscp("true");
```

override_node2_mgmt_ipv6_dscp( )

The override_node2_mgmt_ipv6_dscp attribute contols whether the DSCP value of the IPv6 MGMT port on node 2 of an HA grid member is used, instead of the Grid default.

The override_node2_mgmt_ipv6_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_node2_mgmt_ipv6_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_node2_mgmt_ipv6_dscp from the member
my $override = $grid_member->override_node2_mgmt_ipv6_dscp();
#Modify override_node2_mgmt_ipv6_dscp
$grid_member->override_node2_mgmt_ipv6_dscp("true");
```

override_ntp_kod( )

The override_ntp_kod attribute controls whether the ntp_kod value in the member is used, instead of the Grid default.

The override_ntp_kod attribute can be specified explicitly. It is also set implicitly when ntp_kod is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_ntp_kod flag or "false" to deactivate it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ntp_kod from the member
my $override = $grid_member->override_ntp_kod();
#Modify override_ntp_kod
$grid_member->override_ntp_kod("true");
```

override_syslog_backup_servers( )

The override_syslog_backup_servers attribute controls whether the syslog_backup_servers value for the Member is used, instead of the Grid default.

The override_syslog_backup_servers attribute can be specified explicitly. It is also set implicitly when syslog_backup_servers is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to set the override_syslog_backup_servers flag or 'false' to deactivate/unset it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get override_syslog_backup_servers of member
my $override_syslog_backup_servers = $grid_member->override_syslog_backup_servers();

#modify override_syslog_backup_servers
$grid_member->override_syslog_backup_servers('true');
```

override_threshold_traps( )

The override_threshold_traps attribute controls whether the threshold_traps value in the member is used, instead of the grid default.

The override_threshold_traps attribute can be specified explicitly. It is also set implicitly when threshold_traps is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_threshold_traps flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_threshold_traps of member
my $override_threshold_traps = $grid_member->override_threshold_traps();
#Set override_threshold_traps
$grid_member->override_threshold_traps("true");
```

override_trap_notifications( )

The override_trap_notifications attribute controls whether the trap_notifications value in the member is used, instead of the grid default.

The override_trap_notifications attribute can be specified explicitly. It is also set implicitly when trap_notifications is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_trap_notifications flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_trap_notifications of member
my $override_trap_notifications = $grid_member->override_trap_notifications();
#Set override_trap_notifications
$grid_member->override_trap_notifications("true");
```

passive_ha_arp_enabled( )

Use this method to set or retrieve the ARP protocol setting on the passive node of an HA pair. If you do not specify a value, the default value is "false". You can only set this value to "true" if the member is an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the passive_ha_arp_enabled flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member passive_ha_arp_enabled
my $passive_ha_arp_enabled = $grid_member->passive_ha_arp_enabled();
#Modify member passive_ha_arp_enabled
$grid_member->passive_ha_arp_enabled("true");
```

platform( )

Use this method to set or retrieve the platform type of a grid member. If you do not specify a value, the default value is "Infoblox".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is one of either "Infoblox", "Cisco", "Riverbed", or "VNIOS".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member platform
my $platform = $grid_member->platform();
#Modify node 2 hardware type
$grid_member->platform("Cisco");
```

prefer_resolver( )

Use this method to set or retrieve the preferred name server of the grid member. The grid member sends queries to this name server first.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are Infoblox::DNS::Nameserver object and Infoblox::DNS::Member object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get preferred resolver
```

```
my $prefer_resolver = $grid_member->prefer_resolver();
#Modify preferred resolver
my $member1 = Infoblox::DNS::Member->new(
    name           => $host_name,
    ipv4addr       => $host_ip,
    stealth        => "false",
    lead           => "false",
    grid_replicate => "false"
);
$grid_member->prefer_resolver($member1);
#Undef prefer resolver
$grid_member->prefer_resolver(undef);
```

pre_provisioning( )

Use this method to set or retrieve the pre-provisioned Grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::Member::PreProvisioning object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get PreProvisioning grid Member
my $pp = $grid_member->pre_provisioning();
#Modify PreProvisioning grid Member
my $hw = Infoblox::Grid::Member::PreProvisioning::Hardware->new(
   hwtype          => 'IB-4010',
   hwmodel         => 'Rev1',
);

my $pp = Infoblox::Grid::Member::PreProvisioning->new(
   hardware_info   => [$hw],
   license         => ['dns', 'dhcp'],
);
$grid_member->pre_provisioning($pp);
```

preserve_if_owns_delegation( )

Use this method to set or retrieve the preserve_if_owns_delegation attribute. If you do not specify a value, the default value is "false".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the preserve_if_owns_delegation flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member preserve_if_owns_delegation
my $preserve_if_owns_delegation  = $grid_member->preserve_if_owns_delegation ();
#Modify member preserve_if_owns_delegation
$grid_member->preserve_if_owns_delegation ("true");
```

query_comm_string( )

Use this method to set or retrieve the Simple Network Management Protocol (SNMP) query community string that the SNMP management system must send together with its queries to the grid member. An SNMP community string is a text string that acts as a password. It is used to authenticate messages that are sent between the management station (the SNMP manager) and the grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Text with the Simple Network Management Protocol (SNMP) query community string with a maximum of 50 bytes. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get query community string
my $query_comm_string = $grid_member->query_comm_string();
#Modify query community string
$grid_member->query_comm_string("test");
#Undef query communication string
$grid_member->query_comm_string(undef);
```

remote_console_access( )

Use this method to set or retrieve the remote_console support access flag of a grid member. When you enable remote console access, a client can access the device using a Secure Shell (SSH) connection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the remote_console_access flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get remote console access flag
my $remote_console_access = $grid_member->remote_console_access();
#Modify remote console access flag
$grid_member->remote_console_access("true");
#Undef remote console access flag
$grid_member->remote_console_access(undef);
```

router_ID( )

Use this method to set or retrieve the virtual router ID of an HA grid member. Required only when the member is an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number with the router identification. Default value is undefined. Valid values should be between 1 and 255

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get router ID
my $router_ID = $grid_member->router_ID();
#Modify router ID
$grid_member->router_ID("34");
```

search_domains( )

Use this method to set or retrieve the Search Domain Group, which is a group of domain names that the Infoblox device can add to partial queries that do not specify a domain name. Note that you can set this parameter only when prefer_resolver or alternate_resolver is set.

Parameter

Valid value is a reference to an array of strings.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get search_domains
my $search_domains = $grid_member->search_domains();
#Modify search_domains
$grid_member->search_domains(["domain1.com", "domain2.com"]);
```

service_status( )

Use this method to retrieve the service status list of a grid member.

Returns

On retrieval, the member returns an array reference that contains Infoblox::Grid::Member::ServiceStatus objects.

Example

```
#Get the service status list
my $services_list = $grid_member->service_status();
```

service_type_configuration( )

Use this method to set or retrieve the configuration option for the member service type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is one of the following: "ALL_V4", "ALL_V6" or "CUSTOM".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the value of service_type_configuration
my $service_type_configuration = $grid_member->service_type_configuration();
# Modify service_type_configuration
$grid_member->service_type_configuration("ALL_V6");
```

snmp_admin( )

Use this method to set or retrieve the Simple Network Management Protocol (SNMP) admin object of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::SNMP::Admin object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get SNMP admin
my $snmp_admin = $grid_member->snmp_admin();
#Modify SNMP admin
my $snmp_admin_obj = Infoblox::Grid::SNMP::Admin->new(
    sysContact_node1  => "Somebody",
    sysDescr_node1    => "SunOS noc1 5.6 Generic_105181-03 sun4u",
    sysLocation_node1 => "Infoblox Headquarter",
    sysName_node1     => "noc1"
);
$grid_member->snmp_admin($snmp_admin_obj);
#Undef snmp admin
$grid_member->snmp_admin(undef);
```

snmpv3_query_users( )

Use this method to set or retrieve the SNMPv3 user setting at the grid level.

Parameter

Valid value is a reference to the list of the Infoblox::Grid::SNMP::User manpage objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get snmpv3_query_users field
my $snmpv3_users = $gridmember->snmpv3_query_users();
my $user = $$snmpv3_users[0];
#Set snmpv3_query_users field
$gridmember->snmpv3_query_users([$user1, $user2]);
```

static_routes( )

Use this method to set or retrieve the static routes list of a grid member. This list contains the static routes of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Member::StaticRoute object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get static routes list
my $static_routes = $grid_member->static_routes();
#Modify static routes list
my $route = Infoblox::Grid::Member::StaticRoute->new(
   "network" => "192.168.2.0/24",
   "gateway" => "192.168.1.1",
);
$grid_member->static_routes([$route]);
```

support_access( )

Use this method to set or retrieve the support access flag of a grid member. This flag enables a Secure Shell (SSH) daemon that only Infoblox Technical Support can access to perform troubleshooting at the grid member level.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the remote_console_access flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get support access flag
my $support_access = $grid_member->support_access();
#Modify support access flag
$grid_member->support_access("true");
#Undef support access
$grid_member->support_access(undef);
```

support_access_info( )

Use this method to retrieve the information string for support access.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get support_access_info
my $support_access_info = $grid_member->support_access_info();
```

syslog_proxy_tcp_port( )

Use this method to set or retrieve the Transmission Control Protocol (TCP) listening port for syslog proxy.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

TCP port number. Default value is 514. Valid values should be between 1 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get syslog proxy tcp port
my $syslog_proxy_tcp_port = $grid_member->syslog_proxy_tcp_port();
#Modify syslog proxy tcp port
$grid_member->syslog_proxy_tcp_port(514);
```

syslog_proxy_udp_port( )

Use this method to set or retrieve the User Datagram Protocol (UDP) listening port for syslog proxy.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

UDP port number. Default value is 514. Valid values should be between 1 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get syslog proxy udp port
my $syslog_proxy_udp_port = $grid_member->syslog_proxy_udp_port();
#Modify syslog proxy udp port
$grid_member->syslog_proxy_udp_port(514);
```

syslog_size( )

Use this method to set or retrieve the grid member syslog rotation size in megabytes.

Parameter

Valid value is between 10 and 300.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get syslog_size
my $syslog_size = $obj->syslog_size();
#Modify syslog_size
$obj->syslog_size(100);
```

syslog_backup_servers( )

Use this method to set or retrieve an array that contains syslog backup server settings for a Grid member.

Setting this method to a defined value implicitly sets the override_syslog_backup_servers method to 'true'. Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_syslog_backup_servers attribute to 'false'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::SyslogBackupServer objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get syslog_backup_servers value
my $servers = $grid_member->syslog_backup_servers();

#modify syslog_backup_servers value
$grid_member->syslog_backup_servers([$server1, $server2]);
```

syslog_server( )

Use this method to set or retrieve the syslog server of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::Grid::SyslogServer object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get syslog server
my $syslog_server = $grid_member->syslog_server();
#Modify syslog server
my $syslog1 = Infoblox::Grid::SyslogServer->new(
    ipv4addr => "44.44.44.44",
    severity => "debug",
);
my $syslog2 = Infoblox::Grid::SyslogServer->new(
    ipv4addr => "55.55.55.55",
    severity => "debug",
);

$grid_member->syslog_server([$syslog1, $syslog2]);
#Undef syslog server
$grid_member->syslog_server(undef);
```

time_zone( )

Use this method to set or retrieve the time zone of the grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The UTC string that represents the time zone. For example "(UTC - 5:00) Eastern Time (US and Canada)". Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get time zone
my $time_zone = $grid_member->time_zone();
#Modify time zone
```

```
$grid_member->time_zone("(UTC - 5:00) Eastern Time (US and Canada)");
#Undef time zone
$grid_member->time_zone(undef);
```

threshold_traps( )

Use this method to retrieve the reference to the list of threshold traps. Each element in the list is a reference to the Infoblox::Grid::SNMP::ThresholdTrap object. If the member inherits traps from the grid, the threshold_traps value is undefined.

Setting this method to a defined value implicitly sets the override_threshold_traps method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_threshold_traps attribute to "false".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

List of Infoblox::Grid::SNMP::ThresholdTrap objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get threshold traps
my $threshold_traps = $member->threshold_traps();
#Modify threshold traps
my $threshold_traps = $member->threshold_traps();
foreach(@$threshold_traps){if $_->trap_name() eq 'Rootfs'; $_->trap_reset=60;} #Change value for
'Rootfs' trap
$grid->threshold_traps($threshold_traps);
$session->modify($member);
```

traffic_capture( )

Use this method to control traffic capture for the specified member. Note that when you use this method, the object MUST be retrieved through a get or search call, or created with an add call.

Parameter

The method accepts an Infoblox::Grid::Member::Capture::Control object as a parameter.

Returns

When passing a capture control object as a parameter, the method returns true if the specified traffic control operation succeeds. It returns false when the operation fails.

If invoked without a parameter, the method returns a Infoblox::Grid::Member::Capture::Status object that describes the current traffic capture status.

Please see the status and control objects for usage examples.

trap_comm_string( )

Use this method to set or retrieve the Simple Network Management Protocol (SNMP) trap community string of the grid member. An SNMP trap community string is a text string that acts as a password. It is used to authenticate messages that are sent between the grid member and the SNMP management systems.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Text with the Simple Network Management Protocol (SNMP) trap community, with a maximum of 50 bytes. Default value is undefined. To undefine trap_comm_string we also need to undefine "trap_receiver" attribute.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get trap community string
my $trap_comm_string = $grid_member->trap_comm_string();
#Modify trap community string
```

```
$grid_member->trap_comm_string("trap_string");
```

trap_notifications( )

Use this method to configure trap notifications. Each element in the list is a reference to the Infoblox::Grid::SNMP::TrapNotification object. If the trap_notifications value is undefined the member inherits trap notifications from the grid.

Explicitly setting this method to a defined value implicitly sets the override_trap_notifications method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_trap_notifications attribute to "false".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Reference to a list of Infoblox::Grid::SNMP::TrapNotification objects. The default value is a reference to a list of all trap notifications.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get a reference to a trap notifications array
my $trap_notifications = $member->trap_notifications();
#Modify trap notifications
my $notifications = $member->trap_notifications();
foreach(@$notifications){if $_->trap_type() eq 'CPU'; $_->enable_email="true";} #Change value for
'CPU' trap
$member->trap_notifications($notifications);
$session->modify($member);
```

trap_receiver( )

Use this method to set or retrieve the Simple Network Management Protocol (SNMP) trap receivers of a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains IPv4 addresses and the Infoblox::Grid::SNMP::TrapReceiver manpage objects. Default value is undefined. To undefine trap_receiver, you must also undefine the "trap_comm_string" attribute.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get trap receiver
my $trap_receiver = $grid_member->trap_receiver();
#Modify trap receiver (SNMPv2)
$grid_member->trap_receiver(["10.0.0.10"]);
#SNMPv3 trap receivers
my $receiver1 = Infoblox::Grid::SNMP::TrapReceiver->new( ip_addr => "19.20.21.22", user => $user);
$gridmember->trap_receiver([$receiver1]);
```

upgrade_group( )

Use this method to set or retrieve the name of the upgrade group to which this Grid member belongs.

Parameter

Valid value is a string representing the upgrade group name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get upgrade_group
my $upgrade group   $obj  upgrade group
```

```
                    =     ->              ();
#Modify upgrade_group
$obj->upgrade_group("group2");
```

use_v4_vrrp( )

Use this method to switch between VRRPv4 and VRRPv6.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to use VRRPv4 or "false" to use VRRPv6.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get use_v4_vrrp
my $use_v4_vrrp = $obj->use_v4_vrrp();
#Modify use_v4_vrrp
$obj->use_v4_vrrp("false");
```

vpn_on_mgmt( )

Use this method to set or retrieve the VPN services on the MGMT port of a grid member that is a single appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that node1_vpn_on_mgmt, node2_vpn_on_mgmt and vpn_on_mgmt share the value; setting any of them will have the same effect.

Parameter

Specify "true" to set the vpn_on_mgmt flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get VPN on MGMT port flag
my $vpn_on_mgmt = $grid_member->vpn_on_mgmt();
#Modify VPN on MGMT port flag
$grid_member->vpn_on_mgmt("false");
```

vlan_id( )

Use this method to set or retrieve the VLAN ID of a grid member.

Parameter

Valid value is an unsigned integer between 1 and 4095 inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $grid_member->vlan_id();
#Modify attribute value
$grid_member->vlan_id(10);
```

create_token( )

Use this function to create the authorization token string for each physical node of the pre-provisioned member.

Parameter

None

Returns

The method returns a reference to an array of Infoblox::Grid::Member::PNodeToken objects.

Example

```
my $tokens = $grid_member->create_token();
```

read_token( )

Use this function to read the authorization token string for each physical node of the pre-provisioned member.

Parameter

None

Returns

The method returns a reference to an array of Infoblox::Grid::Member::PNodeToken objects. If tokens were not created previously, or have already expired, an empty array will be returned.

Example

```
my $tokens = $grid_member->read_token();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify, search and remove. This sample also includes error handling for the operations.

#Preparation prior to getting and modifying a grid member object

```
use strict;
use Infoblox;

#refers to Infoblox Appliance IP address
my $host_ip = "192.168.1.2";

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $sysserv1 = Infoblox::Grid::SyslogServer->new(
    ipv4addr => "7.7.7.7"
);
unless ($sysserv1) {
       die("Construct sysserv1 failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Sysserv1 created successfully\n";
```

#Create a grid member object

```
my $grid_member = Infoblox::Grid::Member->new(
    name          => "hostname.com",
    ipv4addr      => "3.0.0.2",
    mask          => "255.0.0.0",
    gateway       => "3.0.0.1",
    syslog_server => [$sysserv1],
    comment       => "Script Generated"
    );
unless ($grid_member) {
       die("Construct grid member object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
```

```
print "Grid member object created successfully\n";

#Adding the member object to appliance through session
my $response = $session->add( $grid_member );

unless ($response) {
    die("Add grid member failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Grid member added successfully \n";
```

#Search for a grid member object

```
 my @retrieved_objs = $session->search(
     object => "Infoblox::Grid::Member",
     name   => ".*\\.com");
 my $object = $retrieved_objs[0];

 unless ($object) {
        die("Search grid member object failed: ",
                $session->status_code() . ":" . $session->status_detail());
 }
 print "Search grid member object found at least 1 matching entry\n";
```

#Get and modify the member object

```
#Get grid member through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member",
    name   => "hostname.com"
    );
my $grid_member = $retrieved_objs[0];

unless ($grid_member) {
    die("Get grid member object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Get grid member successful \n";

# Modify one of the attributes of selected grid member.

$grid_member->comment("Modified member object");

#Applying the changes
$session->modify($grid_member)
   or die("Modify grid member failed",
            $session->status_code() . ":" . $session->status_detail());
print"Grid member modified successfully \n";
```

#Remove the grid member object

```
#Get grid member through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member",
    name   => "hostname.com"
    );
my $desired_grid_member = $retrieved_objs[0];

unless ($desired_grid_member) {
    die("Get grid member object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Get grid member successful \n";

#Submit the object for removal
$session->remove( $desired_grid_member )
    or die("Remove grid member failed",
            $session->status_code() . ":" . $session->status_detail());
print"Grid member removed successfully \n";

####PROGRAM ENDS####
```

NAME

Infoblox::Grid::Member::BGP::AS - BGP (Border Gateway Protocol) Autonomous System (AS) object.

DESCRIPTION

An Infoblox::BGP::AS object represents a BGP Autonomous System configured at the grid member level.

CONSTRUCTOR

```
my $bgp_as = Infoblox::Grid::Member::BGP::AS->new(
    as              => $num,                          # Optional / Default value is undefined
    keepalive       => $num,                          # Optional / Default value is 4
    holddown        => $num,                          # Optional / Default value is 16
    neighbors       => [ $neighbor1, $neighbor2, ... ], # Optional / Default value is empty
);
```

MODULE METHODS

The following functions can be applied to a BGP AS object.

Infoblox::Grid::Member->bgp_as( )

Use this function to specify BGP Autonomous Systems for the grid member. See Infoblox::Grid::Member->bgp_as() for parameters and return values.

Example

```
#Construct a BGP neighbor
my $neighbor = Infoblox::Grid::Member::BGP::Neighbor->new(
    neighbor_ip          => "172.16.0.1",
    remote_as            => 1234,
    interface            => "LAN_HA",
);

#Construct a BGP AS
my $autonomous_system = Infoblox::Grid::Member::BGP::AS->new(
    as          => 269,
    keepalive       => 4,
    holddown        => 16,
    neighbors       => [ $neighbor ]
);

# Configure BGP on the Grid Member object
my $response = $Grid_Member->bgp_as([$as]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Infoblox::BGP::AS object.

as( )

Use this method to set or retrieve the number of this AS.

A valid AS number is required to advertise to neighbors defined in this AS.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An AS number is a 16-bit integer from 1 to 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get AS number
my $as_number = $autonomous_system->as();
#Modify AS number
$autonomous_system->as(300);
```

keepalive( )

Use this method to set or retrieve the AS keepalive timer.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of seconds for the keepalive timer. The valid value is from 1 to 21845 seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get AS keepalive timer
my $keepalive = $autonomous_system->keepalive();
#Modify AS keepalive timer
$autonomous_system->keepalive(3600);
```

holddown( )

Use this method to set or retrieve the AS hold down timer.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of seconds for the hold down timer. The valid value is from 3 to 65535 seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get Autonomous System hold down timer
my $holddown = $autonomous_system->holddown();
#Modify Autonomous System hold down timer
$autonomous_system->holddown(3600);
```

neighbors( )

Use this method to set or retrieve the BGP neighbors for the Infoblox::BGP::AS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::Member::BGP::Neighbor object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get AS neighbor list
my $neighbors = $autonomous_system->neighbors();
#Modify AS neighbors
$autonomous_system->neighbors( [ $neighbor1, $neighbor2 ] );
```

NAME

Infoblox::Grid::Member::BGP::Neighbor - BGP (Border Gateway Protocol) neighbor object

DESCRIPTION

An Infoblox::BGP::Neighbor object represents the BGP neighbor that is configured in an Autonomous System (AS). BGP neighbors are configured at the grid member level.

CONSTRUCTOR

```
my $neighbor = Infoblox::Grid::Member::BGP::Neighbor->new(
    neighbor_ip          => $ipv4addr | $ipv6addr, # Required
    remote_as            => $num,                  # Required
    bgp_neighbor_pass    => $string,               # Required if  authentication_mode set to "MD5"
    authentication_mode  => "NONE" | "MD5",        # Optional / default is "NONE"
    bfd_template         => $string,               # Optional / default is undefined
    comment              => $string,               # Optional / default is undefined
    enable_bfd           => "true" | "false",      # Optional / default is "false"
    enable_multihop      => "true" | "false",      # Optional / default is "false"
    interface            => $string,               # Optional / default is "LAN_HA"
    multihop_ttl         => $uint | undef,         # Optional / default is undefined
);
```

MODULE METHODS

The following functions can be applied to a BGP AS object.

Infoblox::Grid::Member::BGP::AS->neighbors( )

Use this function to specify BGP Autonomous Systems for the grid member. See Infoblox::Grid::Member::BGP::AS->neighbors() for parameters and return values.

Example

```
#Construct a BGP neighbor
my $neighbor = Infoblox::Grid::Member::BGP::Neighbor->new(
    neighbor_ip           => "172.16.0.1",
    remote_as             => 1234,
    authentication_mode   => "NONE",
    interface             => "LAN_HA",
);

#Construct a BGP AS
my $autonomous_system = Infoblox::Grid::Member::BGP::AS->new(
    as          => 269,
    keepalive       => 4,
```

```
    holddown        => 16,
    neighbors       => [ $neighbor ]
);

# Configure BGP on the Grid Member object
my $response = $Grid_Member->bgp_as([$as]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Infoblox::BGP::AS object.

enable_multihop( )

Use this method to set or retrieve the flag that indicates whether the multihop option is enabled or not.

By default, BGP connects to external peers residing on directly connected networks. Usually the ttl in IP header (hop-limit IPv6) is set to 1 to avoid BGP packets crossing networks. EBGP multihop option allows connection to peers which have one or more non-BGP routers in between.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable multihop option and 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_multihop value
my $enable_multihop = $object->enable_multihop();
#Modify enable_multihop value
$object->enable_multihop("true");
```

enable_bfd( )

Use this method to set or retrieve the flag that indicates whether the Bidirectional Forwarding Detection (BFD) fallover is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable BFD fallover and false to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_bfd value
my $enable_bfd = $object->enable_bfd();
#Modify enable_bfd value
$object->enable_bfd('true');
```

interface( )

Use this method to set or retrieve the interface that sends BGP advertisement information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the interface in string format. The only supported value is "LAN_HA".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interface
my $interface = $neighbor->interface();
#Modify interface
$neighbor->interface("LAN_HA");
```

multihop_ttl( )

Use this method to set or retrieve the TTL setting for multihop option.

By default, BGP connects to external peers residing on directly connected networks. Usually the ttl in IP header (hop-limit IPv6) is set to 1 to avoid BGP packets crossing networks. EBGP multihop option allows connection to peers which have one or more non-BGP routers in between.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 255. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get multihop_ttl value
my $multihop_ttl = $object->multihop_ttl();
#Modify multihop_ttl value
$object->multihop_ttl(200);
```

neighbor_ip( )

Use this method to set or retrieve the IP address of the BGP neighbor.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The IPv4 or IPv6 address of the BGP neighbor.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get neighbor IP address
my $neighbor_ip = $neighbor->neighbor_ip();
#Modify neighbor IP address
$neighbor->neighbor_ip("192.168.1.2");
$neighbor->neighbor_ip("2001::1");
```

remote_as( )

Use this method to set or retrieve the remote AS number of the BGP neighbor.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An AS number is a 16-bit number from 1 to 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get neighbor remote AS number
my $remote_as = $neighbor->remote_as();
#Modify remote AS number
```

```
$neighbor->remote_as(269);
```

authentication_mode( )

Use this method to set or retrieve the attribute about whether BGP authentication has been set for each neighbor.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set parameter to "MD5" to enable BGP authentication for a definite neighbor.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get neighbor enable authentication
my $remote_as = $neighbor->authentication_mode();
#Modify enable authentication
$neighbor->authentication_mode("MD5");
```

bfd_template( )

Use this method to set or retrieve the Bidirectional Forwarding Detection (BFD) template name.

BFD template is used to configure advanced BFD settings such as timer intervals, authentication.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired BFD template in string format. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bfd_template value
my $bfd_template = $object->bfd_template();
#Modify bfd_template value
$object->bfd_template("template1");
```

bgp_neighbor_pass( )

Use this method to set the password for a BGP neighbor. This is required only if authentication_mode is set to "MD5". When the password is entered, the value is preserved even if authentication_mode is changed to "NONE". This is a write-only attribute.

Parameter

The bgp_neighbor_pass in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify authentication password per neighbor
$neighbor->bgp_neighbor_pass("authpassword");
```

comment( )

Use this method to set or retrieve a descriptive comment.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get neighbor comment
my $comment = $neighbor->comment();
#Modify comment
$neighbor->comment("my comment");
```

NAME

Infoblox::Grid::Member::CapacityReport - Capacity report for a specified member.

DESCRIPTION

This is a read-only object that provides the capacity report for the specified member.

CONSTRUCTOR

The Infoblox::Grid::Member::CapacityReport object is a read-only object and does not require manual construction.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to the Infoblox::Grid::HSM::AllGroup object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

Apply the following attribute to get a specific capacity report object:

```
name - Required. A member name.
```

Example

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member::CapacityReport",
    name   => "infoblox.localdomain"
    );
```

METHODS

This section describes all the methods that you can use to retrieve the attribute values of the Infoblox::Grid::Member::CapacityReport object.

hardware_type( )

Use this method to retrieve the member's hardware type.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get hardware_type
my $hardware_type = $report->hardware_type();
```

max_capacity( )

Use this method to retrieve the member's maximum object capacity.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get max_capacity
my $max_capacity = $report->max_capacity();
```

name( )

Use this method to retrieve the member name.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get name
my $name = $report->name();
```

object_counts( )

Use this method to retrieve the object counts for the member.

Parameter

None

Returns

The method returns the attribute value, which is a reference to a hash that contains keys to the object types and the corresponding values to the counts of each particular object type.

Example

```
#Get object_counts
my $object_counts = $report->object_counts();
#Get the zone count
my $zone_count = $object_counts->{'Zone'};
```

percent_used( )

Use this method to retrieve the percentage of the member capacity currently being used.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get percent_used
my $percent_used = $report->percent_used();
```

role( )

Use this method to retrieve the member role.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get role
my $role = $report->role();
```

total_objects( )

Use this method to retrieve the total number of objects on the member.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get total_objects
my $total_objects = $report->total_objects();
```

NAME

Infoblox::Grid::Member::CaptivePortal - Captive Portal object.

DESCRIPTION

This object represents the captive portal configuration.

CONSTRUCTOR

The Infoblox::Grid::Member::CaptivePortal object is automatically generated upon the successful installation of the Infoblox appliance. It does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a Captive Portal object.

Infoblox::Session->get( )

Use this method to retrieve matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific Captive Portal object:

 name - Required. A domain name in string format.
```

Example

```
my @retrieved objs   $session  get
```

```
                =          ->    (
object => "Infoblox::Grid::Member::CaptivePortal",
name   => "infoblox.localdomain"
);
```

Infoblox::Session->modify( )

Use this method to modify objects in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use this method to modify the welcome message.
$captive_portal->welcome_message("New welcome message");
#Submit modification
my $response = $session->modify( $captive_portal );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the captive portal.

authn_server_group ( )

Use this method to set or retrieve the authentication server group assigned to this captive portal.

Parameter

The valid values are an Infoblox::Grid::Admin::AdAuthService, an Infoblox::Grid::Admin::RadiusAuthService or an Infoblox::LDAP::AuthService object. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting authn_server_group
my $authn_server_group = $captive_portal->authn_server_group();
#Modifying authn_server_group
$captive_portal->authn_server_group($adservice);
```

company_name ( )

Use this method to set or retrieve the company name that appears in the guest registration page.

Parameter

The valid value is a string. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting company_name
my $company_name = $captive_portal->company_company_name();
#Modifying company_name
$captive_portal->company_name('Company Name');
```

enable_syslog_auth_failure ( )

Use this method to set or retrieve the flag that controls whether authentication failures are logged to syslog.

Parameter

Specify "true" to enable logging or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_syslog_auth_failure
```

```
my $enable_syslog_auth_failure = $captive_portal->enable_syslog_auth_failure();
#Modifying enable_syslog_auth_failure
$captive_portal->enable_syslog_auth_failure('true');
```

enable_syslog_auth_success ( )

Use this method to set or retrieve the flag that controls whether successful authentications are logged to syslog.

Parameter

Specify "true" to enable logging or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_syslog_auth_success
my $enable_syslog_auth_success = $captive_portal->enable_syslog_auth_success();
#Modifying enable_syslog_auth_success
$captive_portal->enable_syslog_auth_success('false');
```

enable_user_type ( )

Use this method to set or retrieve the type of user to be enabled for the captive portal.

Parameter

Valid values are "Authenticated", "Guest" or "Both". The default value is "Authenticated".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_user_type
my $enable_user_type = $captive_portal->enable_user_type();
#Modifying enable_user_type
$captive_portal->enable_user_type('Both');
```

encryption ( )

Use this method to set or retrieve the encryption the captive portal uses.

Parameter

Valid values are 'None' or 'SSL'. The default value is 'None'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting encryption
my $encryption = $captive_portal->encryption();
#Modifying encryption
$captive_portal->encryption('SSL');
```

files ( )

Use this method to set or retrieve the list of files associated with the captive portal.

Parameter

The valid value is an array reference that contains Infoblox::Grid::Member::CaptivePortal::File object(s). New files must be added using Infoblox::Session->import_data(). However, if a file is removed from this list, it is also removed from the captive portal.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting files
my $files = $captive_portal->files();
#Modifying files
$captive_portal->files([$logo]);
```

guest_custom_field1_name ( )

Use this method to set or retrieve the name of the custom field that you are adding to the guest registration page.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 200 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field1_name
my $guest_custom_field1_name = $captive_portal->guest_custom_field1_guest_custom_field1_name();
#Modifying guest_custom_field1_name
$captive_portal->guest_custom_field1_name('Extra field 1');
```

guest_custom_field1_required ( )

Use this method to set or retrieve the flag that controls whether the custom field is required.

Parameter

Specify "true" to set the flag or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field1_required
my $guest_custom_field1_required = $captive_portal->guest_custom_field1_required();
#Modifying guest_custom_field1_required
$captive_portal->guest_custom_field1_required('true');
```

guest_custom_field2_name ( )

Use this method to set or retrieve the name of the custom field that you are adding to the guest registration page.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 200 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field2_name
my $guest_custom_field2_name = $captive_portal->guest_custom_field2_guest_custom_field2_name();
#Modifying guest_custom_field2_name
$captive_portal->guest_custom_field2_name('Extra field 2');
```

guest_custom_field2_required ( )

Use this method to set or retrieve the flag that controls whether the custom field is required.

Parameter

Specify "true" to set the flag or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field2_required
my $guest_custom_field2_required = $captive_portal->guest_custom_field2_required();
#Modifying guest_custom_field2_required
$captive_portal->guest_custom_field2_required('true');
```

guest_custom_field3_name ( )

Use this method to set or retrieve the name of the custom field that you are adding to the guest registration page.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 200 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field3_name
my $guest_custom_field3_name = $captive_portal->guest_custom_field3_guest_custom_field3_name();
#Modifying guest_custom_field3_name
$captive_portal->guest_custom_field3_name('Extra field 3');
```

guest_custom_field3_required ( )

Use this method to set or retrieve the flag that controls whether the custom field is required.

Parameter

Specify "true" to set the flag or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field3_required
my $guest_custom_field3_required = $captive_portal->guest_custom_field3_required();
#Modifying guest_custom_field3_required
$captive_portal->guest_custom_field3_required('true');
```

guest_custom_field4_name ( )

Use this method to set or retrieve the name of the custom field that you are adding to the guest registration page.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 200 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field4_name
my $guest_custom_field4_name = $captive_portal->guest_custom_field4_guest_custom_field4_name();
#Modifying guest_custom_field4_name
$captive_portal->guest_custom_field4_name('Extra field 4');
```

guest_custom_field4_required ( )

Use this method to set or retrieve the flag that controls whether the custom field is required.

Parameter

Specify "true" to set the flag or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field4_required
my $guest_custom_field4_required = $captive_portal->guest_custom_field4_required();
#Modifying guest_custom_field4_required
$captive_portal->guest_custom_field4_required('true');
```

guest_email_required ( )

Use this method to set or retrieve the flag that controls whether the email address of the guest is required.

Parameter

Specify "true" to set this flag or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_email_required
my $guest_email_required = $captive_portal->guest_email_required();
#Modifying guest_email_required
$captive_portal->guest_email_required('false');
```

guest_first_name_required ( )

Use this method to set or retrieve the flag that controls whether the first name of the guest is required.

Parameter

Specify "true" to enable or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_first_name_required
my $guest_first_name_required = $captive_portal->guest_first_name_required();
#Modifying guest_first_name_required
$captive_portal->guest_first_name_required('false');
```

guest_last_name_required ( )

Use this method to set or retrieve the flag that controls whether the last name of the guest is required.

Parameter

Specify "true" to set the flag or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_last_name_required
my $guest_last_name_required = $captive_portal->guest_last_name_required();
#Modifying guest_last_name_required
$captive_portal->guest_last_name_required('false');
```

guest_middle_name_required ( )

Use this method to set or retrieve the flag that controls whether the middle name of the guest is required.

Parameter

Specify "true" to set the flag or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_middle_name_required
my $guest_middle_name_required = $captive_portal->guest_middle_name_required();
#Modifying guest_middle_name_required
$captive_portal->guest_middle_name_required('true');
```

guest_phone_required ( )

Use this method to set or retrieve the flag that controls whether the phone number of the guest is required.

Parameter

Specify "true" to set this flag or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_phone_required
my $guest_phone_required = $captive_portal->guest_phone_required();
#Modifying guest_phone_required
$captive_portal->guest_phone_required('false');
```

helpdesk_message ( )

Use this method to set or retrieve the helpdesk message that appears in the guest registration page.

Parameter

The valid value is a string. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting helpdesk_message
my $helpdesk_message = $captive_portal->helpdesk_message();
#Modifying helpdesk_message
$captive_portal->helpdesk_message('In case of problems, please contact us at 555-555-5555');
```

listen_address ( )

Use this method to set or retrieve the IP address on which the captive portal listens.

Parameter

The valid values are 'VIP', 'LAN2' or an IPv4 address. The default value is 'VIP'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting listen_address
my $listen_address = $captive_portal->listen_address();
#Modifying listen_address
$captive_portal->listen_address('VIP');
```

name ( )

Use this method to retrieve the hostname of the grid member that hosts the captive portal.

Returns

The method returns the attribute value.

Example

```
#Getting name
my $name = $captive_portal->name();
```

network_view ( )

Use this method to set or retrieve the network view of the captive portal.

Parameter

The valid value is a network view name. The default is the system default network view.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting network_view
my $network_view = $captive_portal->network_view();
#Modifying network_view
$captive_portal->network_view('otherview');
```

port ( )

Use this method to set or retrieve the TCP port used by the Captive Portal service. The port is required when the Captive Portal service is enabled.

Parameter

Valid values are between 1 and 63999. The default value is 4433. Please note that setting the port number to 80 or 443 might impact performance.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting the port
my $port = $captive_portal->port();
#Modifying the port
$captive_portal->port(4457);
```

service_enabled ( )

Use this method to set or retrieve the state of the captive portal service.

Parameter

Specify "true" to enable the service or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting service_enabled
my $service_enabled = $captive_portal->service_enabled();
#Modifying service_enabled
$captive_portal->service_enabled('false');
```

syslog_auth_failure_level ( )

Use this method to set or retrieve the syslog level at which authentication failures are logged.

Parameter

Valid values are "debug", "info", "notice", "warning", "err", "crit", "alert" or "emerg" . The default value is "info".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting syslog_auth_failure_level
my $syslog_auth_failure_level = $captive_portal->syslog_auth_failure_level();
#Modifying syslog_auth_failure_level
$captive_portal->syslog_auth_failure_level('notice');
```

syslog_auth_success_level ( )

Use this method to set or retrieve the syslog level at which successful authentications are logged.

Parameter

Valid values are "debug", "info", "notice", "warning", "err", "crit", "alert" or "emerg" . The default value is "info".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting syslog_auth_success_level
my $syslog_auth_success_level = $captive_portal->syslog_auth_success_level();
#Modifying syslog_auth_success_level
$captive_portal->syslog_auth_success_level('warning');
```

welcome_message ( )

Use this method to set or retrieve the welcome message that appears in the guest registration page.

Parameter

The valid value is a string. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting welcome_message
my $welcome_message = $captive_portal->welcome_message();
#Modifying welcome_message
$captive_portal->welcome_message('Welcome to our network!');
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to a captive portal object, such as get and modify an object. This sample code also includes error handling for the operations.

#Preparation prior to operations on a captive portal object

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

# Upload a new AUP to the captive portal, from now on
# the files() method will contain an Infoblox::Grid::Member::CaptivePortal::File
# object referencing this.
$session->import_data(
                      type     => 'captive_portal_file',
```

```
                        path    => 'aup.txt',
                        member  => '192.168.1.2',
                        cp_type => 'aup'
    )
    or die("file import failed: ",
            $session->status_code(), $session->status_detail());

    my $ads1 = Infoblox::Grid::Admin::RadiusAuthServer->new(
                                                            comment  => 'server 1',
                                                            fqdn_or_ip => '10.0.1.1',
                                                            shared_secret => 'secret1',
                                                           );

    my $ads2 = Infoblox::Grid::Admin::RadiusAuthServer->new(
                                                            comment  => 'server 2',
                                                            fqdn_or_ip => 'domain.com',
                                                            shared_secret => 'secret2',
                                                          );
```

#Create the RADIUS Auth Service.

```
    my $service = Infoblox::Grid::Admin::RadiusAuthService->new(
                                                                acct_retries   => 2000,
                                                                auth_retries   => 9,
                                                                cache_ttl      => 500,
                                                                disabled       => 'true',
                                                                enable_cache   => 'true',
                                                                recovery_ttl   => 50,
                                                                selection_mode => 'ROUND_ROBIN',
                                                                acct_timeout   => 1100,
                                                                auth_timeout   => 1200,
                                                                name           => 'some.name.com',
                                                                radius_servers => [$ads1, $ads2]
                                                              );

    unless($service){
           die("Construct service object failed: ",
                   Infoblox::status_code(). ":" .Infoblox::status_detail());
           }
    print "service object object created successfully.\n";

    $session->add($service)
        or die("Add service object failed: ",
                   $session->status_code(). ":" .$session->status_detail());

    print"Service object added successfully.\n";
```

#Get and modify the captive portal property object.

```
    #Get the captive portal object. Considering the id grid member named infoblox.localdomain was previously
created.
    my @object = $session->get(
        object => "Infoblox::Grid::Member::CaptivePortal",
        name   => "infoblox.localdomain"
        )
        or die("get captive portal failed: ",
             $session->status_code(), $session->status_detail());

    #Modify captive portal object.
    unless (scalar(@object) == 0) {
        my $object = $object[0];

        if ($object) {
            $object->authn_server_group($service);
            $object->guest_phone_required('false');
            $object->guest_custom_field1_name('Custom field 1');
            $object->guest_custom_field1_required('true');
            $object->guest_custom_field2_name('Custom field 2');
            $object->guest_custom_field2_required('true');

            # This will remove the AUP uploaded above
            $object->files([]);

            #Applying the changes
            $session->modify($object)
                or die("Modify captive portal failed: ",
                     $session->status_code(), $session->status_detail());

        }
```

```
    } else {
   print "No grid captive portal found.";
    }

NAME

Infoblox::Grid::Member::CaptivePortal::File - Captive Portal File object

DESCRIPTION

This object is used to represent files uploaded to the captive portal. All methods are read-only.

MODULE METHODS

The following functions can be applied to a CaptivePortal::File object.

Infoblox::Grid::Member::CaptivePortal->files( )

Use this function to retrieve a reference to an array of Infoblox::Grid::Member::CaptivePortal::File objects that represent the files uploaded to the captive portal.

Example

```
#Retrieve the captive portal object
my $member = $session->get(object => 'Infoblox::Grid::Member::CaptivePortal', name =>
'cportal.com');

# Access its files
my @files = @{$member->files()};
print $files[0]->name();
```

METHODS

This section describes all the methods that you can use to retrieve the attribute value of a file uploaded to a captive portal.

name( )

Use this method to retrieve the name of the uploaded file.

Returns

The method returns the attribute value.

Example

```
#Get name
my $name = $service_status->name();
```

type( )

Use this method to retrieve the type of the uploaded file.

Returns

The method returns the attribute value. Valid values are "Logo", "Footer", "Header", and "AUP"

Example

```
#Get type
my $type = $service_type->type();
```

NAME

Infoblox::Grid::Member::Capture::Control - Traffic capture control object

---

DESCRIPTION

You can control traffic capture for a grid member via the settings in this object.

CONSTRUCTOR

```
my $control = Infoblox::Grid::Member::Capture::Control->new(
              action         => "START" | "STOP",                          # Required
              interface      => "ALL" | "HA" | "LAN1" | "LAN2" | "MGMT",# Required
              seconds_to_run => $num,                                      # Required
);
```

MODULE METHODS

The following functions are available to be applied to a traffic capture control object.

Infoblox::Grid::Member->traffic_capture( )

Use this function to control traffic capture for the Grid Member. See Infoblox::Grid::Member->traffic_capture() for parameters and return values. Note that the member object must be retrieved from the appliance in order for the traffic capture method to be available.

METHODS

This section describes all the methods that you can use to control traffic capture for a grid member.

action( )

Use this method to select the traffic capture action.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "START" or "STOP".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Setting the action
$control->action("START");
```

interface( )

Use this method to specify the interface on which you capture traffic.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "ALL", "HA", "LAN", "LAN2" or "MGMT".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Choosing the interface
$control->interface("ALL");
```

seconds_to_run( )

Use this method to select the number of seconds for which you want to run the traffic capture.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an integer specifying the number of seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Setting the capture interfal
$control->seconds_to_run(5);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a capture control object. This sample also includes error handling for the operations.

#Preparation prior to traffic capture object operations

```
#PROGRAM STARTS: Include all the modules that will be used

use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Start traffic capture for a member

```
# Get the grid member object.
my $object = $session->get(
    object => "Infoblox::Grid::Member",
    name => "infoblox.localdomain",
);

unless ($object) {
      die("get grid member failed: ",
      $session->status_code() . ":" . $session->status_detail());
}
print "grid member get successful\n";
```

```
my $capture = Infoblox::Grid::Member::Capture::Control->new(
                                                            action => 'START',
                                                            interface => 'ALL',
                                                            seconds_to_run => 2,
                                                           );
unless ($object->traffic_capture($capture)) {
      die("traffic capture failed: ",
      $session->status_code() . ":" . $session->status_detail());
}

print "traffic capture started\n";

NAME

Infoblox::Grid::Member::Capture::Status - Traffic capture status object

---

DESCRIPTION

You can retrieve the traffic capture status for a grid member via this object.

MODULE METHODS

The following functions are available to be applied to a traffic capture status object.

Infoblox::Grid::Member->traffic_capture( )

Use this function to retrieve the traffic capture status for the Grid Member. See Infoblox::Grid::Member->traffic_capture() for parameters and return values. Note that the member object must be retrieved from the appliance in order for the traffic capture method to be available.

METHODS

This section describes all the methods that explain a grid member's traffic capture status. All members are read-only.

file_exists( )

Use this method to retrieve a traffic capture file if it exists for the member. If the file exists, it can be downloaded using the export_data method in Infoblox::Session.

Returns

The method returns the attribute value, which can be "true" or "false".

Example

```
#Get file_exists
$exists = capstatus->file_exists();
```

file_size( )

Use this method to retrieve the size of the traffic capture file for the member.

Returns

The method returns the attribute value, which is the file size in bytes.

Example

```
#Get the file_size
$size = capstatus->file_size();
```

status( )

Use this method to retrieve the status of the capture operation for the grid member.

Returns

The method returns the attribute value, which can be "RUNNING", "STOPPED" or "UNKNOWN".

Example

```
#Get the status
$status = capstatus->status();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a capture status object. This sample also includes error handling for the operations.

#Preparation prior to traffic capture object operations

```
#PROGRAM STARTS: Include all the modules that will be used

use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Start traffic capture for a member

```
# Get the grid member object.
my $object = $session->get(
    object => "Infoblox::Grid::Member",
    name => "infoblox.localdomain",
);

unless ($object) {
      die("get grid member failed: ",
      $session->status_code() . ":" . $session->status_detail());
}
print "grid member get successful\n";

my $capture = Infoblox::Grid::Member::Capture::Status->new(
                                                            action => 'START',
                                                            interface => 'ALL',
                                                            seconds_to_run => 2,
                                                           );
unless ($object->traffic_capture($capture)) {
      die("traffic capture failed: ",
      $session->status_code() . ":" . $session->status_detail());
}

print "traffic capture started\n";

my $capstatus = $object->traffic_capture();

print "The capture is " . $capstatus->status() . "\n";

####PROGRAM ENDS####

NAME

Grid::Member::Communication - Grid::Member::Communication object.

DESCRIPTION

The structure stores information regarding service, transport type and preference.

MODULE METHODS

The following functions can be applied to a communication object.

Infoblox::Grid::Member->member_service_communication( )

Use this function to retrieve a reference to an array of Infoblox::Grid::Member::Communication objects that represents the communication settings for an Infoblox appliance.

Example

```
#Retrieve the member object
my $member = $session->get(object => 'Infoblox::Grid::Member', name => 'hostname.com');

# Access its communication settings
my @communication = @{$member->member_service_communication()};
print $communications[0]->type();
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

option( )

Use this method to retrieve the flag when the service is either forced to use one type of transport or have a preference for the transport type. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value, which can be either "FORCE" or "PREFER".

Example

```
#Get option
my $option = $comm->option();
```

service( )

Use this method to set or retrieve services for which communication type can be configured.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is one of the following: "GRID", "GRID_BACKUP", "NTP", "REPORTING", "REPORTING_BACKUP", "OCSP", "MAIL",

"AD".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get service
my $service = $comm->service();
# Modifying service
$comm->service("GRID");
```

type( )

Use this method to set or retrieve the transport type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is IPv4 or IPv6.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get type
my $type = $comm->type();
# Modifying type
$comm->type("IPv4");
```

NAME

Infoblox::Grid::Member::DHCP - DHCP member object.

DESCRIPTION

When you configure an Infoblox appliance to function as a DHCP server, you can set certain properties that control how the server

operates. You can also specify the configuration information the server includes in its DHCP messages. When a DHCP server assigns an IP address to a client, it can include configuration information the client needs to connect to the network and communicate with other hosts and appliances in the network.

Though you can set general DHCP properties at the grid level, you enable DHCP services at the member level only. Infoblox recommends that you configure the DHCP parameters before you enable DHCP on the Infoblox appliance.

CONSTRUCTOR

The Infoblox::Grid::Member::DHCP object is automatically generated upon the successful installation of the Infoblox appliance. It does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a member DHCP object.

Infoblox::Session->get( )

Use this method to retrieve matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

Apply the following attribute to get a specific member DHCP object:

```
name - Optional. A domain name in string format.
ipv4addr - Optional.   IPv4 address of the member
ipv6addr - Optional.   IPv6 address of the member
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member::DHCP",
    name   => "infoblox.localdomain"
    );

# get all Grid::Member::DHCP objects with a given extensible attribute
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member::DHCP",
    extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify objects in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify dhcp service.
$member_dhcp->enable_dhcp("true");
#Submit modification
my $response = $session->modify( $member_dhcp );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the DHCP properties of a grid member.

auth_server_group( )

Use this method to set or retrieve the Authentication Server Group object associated with this member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An Infoblox::Grid::Admin::RadiusAuthService object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting auth_server_group

my $auth_server_group = $memberdhcp->auth_server_group( );
#Modifying auth_server_group
$auth_server_group->$memberdhcp($radius_service);
```

authority( )

Use this method to set or retrieve the authority flag of a grid member. This flag specifies if a DHCP server is authoritative for a domain.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the authority flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get authority
my $authority = $memberdhcp->authority();
#Modify authority
$memberdhcp->authority("true");
```

authn_captive_portal

The captive portal responsible for authentications for this DHCP member.

Parameter

The valid value is a name in FQDN format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get authn_captive_portal
my $authn_captive_portal = $memberdhcp->authn_captive_portal();
#Modify authn_captive_portal
$memberdhcp->authn_captive_portal("cpmember.com");
```

authn_captive_portal_authenticated_filter

The MAC filter representing the authenticated range.

Parameter

The valid value is an Infoblox::DHCP::Filter::MAC object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get authn_captive_portal_authenticated_filter
my $authn_captive_portal_authenticated_filter = $memberdhcp-
>authn_captive_portal_authenticated_filter();
#Modify authn_captive_portal_authenticated_filter
$memberdhcp->authn_captive_portal_authenticated_filter($macfilter);
```

authn_captive_portal_enabled

Use this method to set or retrieve the flag that controls if this DHCP member is enabled for captive portal authentication.

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get authn_captive_portal_enabled
my $authn_captive_portal_enabled = $memberdhcp->authn_captive_portal_enabled();
#Modify authn_captive_portal_enabled
$memberdhcp->authn_captive_portal_enabled("true");
```

authn_captive_portal_guest_filter

The MAC filter representing the guest range.

Parameter

The valid value is an Infoblox::DHCP::Filter::MAC object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get authn_captive_portal_guest_filter
my $authn_captive_portal_guest_filter = $memberdhcp->authn_captive_portal_guest_filter();
#Modify authn_captive_portal_guest_filter
$memberdhcp->authn_captive_portal_guest_filter($macfilter);
```

auth_server_group_enabled

Use this method to set or retrieve the flag that controls if this DHCP member can send authentication requests to an authentication server group.

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get auth_server_group_enabled
my $auth_server_group_enabled = $memberdhcp->auth_server_group_enabled();
#Modify auth_server_group_enabled
$memberdhcp->auth_server_group_enabled("true");
```

bootfile( )

Use this method to set or retrieve the name of a file that DHCP clients need to boot. This setting overrides the grid level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::Grid::Member::DHCP->bootserver() and Infoblox::Grid::Member::DHCP->nextserver().

Parameter

The name of the file that the client must download. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootfile
my $bootfile = $memberdhcp->bootfile();
#Modify bootfile
$memberdhcp->bootfile("bootfile.txt");
#Un-override bootfile
$memberdhcp->bootfile(undef);
```

bootserver( )

Use this method to set or retrieve the name of the server on which a boot file is stored. This setting overrides the grid level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::Grid::Member::DHCP->bootfile() and Infoblox::Grid::Member::DHCP->nextserver().

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootserver
my $bootserver = $memberdhcp->bootserver();
#Modify bootserver
$memberdhcp->bootserver("hostname.com");
#Un-override bootserver
$memberdhcp->bootserver(undef);
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname value. Set this value to enable/disable the ability of a member DHCP server to generate a host name and update DNS with this host name when it receives a DHCP REQUEST message that does not include a host name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable this feature or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_generate_hostname
my $ddns_generate_hostname = $memberdhcp->ddns_generate_hostname();
#Modify disable
$memberdhcp->ddns_generate_hostname("true");
```

ddns_retry_interval( )

Use this method to set or retrieve the ddns_retry_interval value. Set the retry interval when the member DHCP server makes repeated attempts to send DDNS updates to a DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the retry interval in minutes. The default retry interval is five minutes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_retry_interval
my $ddns_retry_interval = $memberdhcp->ddns_retry_interval();
#Modify ddns_retry_interval
$memberdhcp->ddns_retry_interval(10);
```

ddns_server_always_updates( )

Use this method to set or retrieve the ddns_server_always_updates value of a member DHCP server. Select this check box to allow only the DHCP server to update DNS,regardless of the requests from the DHCP clients. This setting overrides the grid level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set ddns_server_always_updates flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_server_always_updates
my $ddns_server_always_updates = $memberdhcp->ddns_server_always_updates();
#Modify ddns_server_always_updates
$memberdhcp->ddns_server_always_updates("true");
```

ddns_ttl( )

Use this method to set or retrieve the ddns_ttl value of a member DHCP server. The DDNS TTL (Dynamic DNS Time To Live) value specifies the number of seconds an IP address for the name is cached.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_dddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that specifies the number of seconds the IP address for the name is cached. Default value is half of lease time.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_ttl
my $ddns_ttl = $memberdhcp->ddns_ttl();
#Modify ddns_ttl
$memberdhcp->ddns_ttl(1000);
```

ddns_domainname( )

Use this method to set or retrieve the member DDNS domain name value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_ddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("domain.com"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("domain.com"); will result in override_ddns_domainname="true".

Parameter

The DDNS domain name in FQDN (Fully Qualified Domain Name) format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $memberdhcp->ddns_domainname();
#Modify ddns_domainname
$memberdhcp->ddns_domainname("domain.com");
```

ddns_update_fixed_addresses( )

Use this method to set or retrieve the ddns_update_fixed_addresses value. Set this value to enable/disable the member DHCP server to update the A and PTR record of clients with a fixed address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the member DHCP server to update the A and PTR record of clients with a fixed address or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_update_fixed_addresses
my $ddns_update_fixed_addresses = $memberdhcp->ddns_update_fixed_addresses();
#Modify ddns_update_fixed_addresses
$memberdhcp->ddns_update_fixed_addresses("true");
```

ddns_use_option81( )

Use this method to set or retrieve the ddns_use_option81 value of a member DHCP server. Set this value to enable/disable support for option 81.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable support for option 81 or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_use_option81
my $ddns_use_option81 = $memberdhcp->ddns_use_option81();
#Modify ddns_use_option81
$memberdhcp->ddns_use_option81("true");
```

ddns_zone_primaries( )

Use this method to set or retrieve an ordered list of zone primaries that will receive DDNS updates.

Parameter

A valid value is a reference to an array of Infoblox::DHCP::DDNS objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
$value = $memberdhcp->ddns_zone_primaries();
# Modify the attribute value
$memberdhcp->ddns_zone_primaries([$ddns]);
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp value of a member DHCP server. Set this value to enable/disable deny_bootp and Grid level.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable deny_bootp or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $memberdhcp->deny_bootp();
#Modify deny_bootp
$memberdhcp->deny_bootp("true");
```

dns_update_style( )

Use this method to set or retrieve the update style for dynamic DNS updates (DHCPv4).

Setting this method to a defined value implicitly sets the override_dns_update_style method to 'true'. Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_dns_update_style attribute to 'false'.

Note that when dns_update_style is set to a defined value and override_dns_update_style is set to 'false', the last operation takes precedence. Thus the sequence $object->dns_update_style('INTERIM'); $object->override_dns_update_style('false'); will set override_dns_update_style to 'false', and the sequence $object->override_dns_update_style('false'); $object->dns_update_style('INTERIM'); will result in override_dns_update_style='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are 'INTERIM' and 'STANDARD'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_update_style value
my $value = $object->dns_update_style();

#Modify dns_update_style value
$object->dns_update_style('STANDARD');
```

email_list( )

Use this method to set or retrieve the email_list value of a member DHCP server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Array reference with the e-mail values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get email_list
my $email_list = $memberdhcp->email_list();
#Modify email_list
$memberdhcp->email_list(["admin\@infoblox.com"]);
```

enable_ddns( )

Use this method to set or retrieve the enable_ddns value of a member DHCP server. Set this value to enable/disable the member DHCP server to send DDNS updates.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable support for DDNS updates or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ddns
my $enable_ddns= $memberdhcp->enable_ddns();
#Modify enable_ddns
$memberdhcp->enable_ddns("true");
```

enable_dhcp( )

Use this method to set or retrieve the enable_dhcp value of a member. Set this value to enable/disable DHCP service.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DHCP or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp
my $enable_dhcp= $memberdhcp->enable_dhcp();
#Modify enable_dhcp
$memberdhcp->enable_dhcp("true");
```

enable_dhcpv6_service( )

Use this method to set or retrieve the enable_dhcpv6_service flag. Set this flag to enable DHCPv6 service for the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_dhcpv6_service method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_enable_dhcpv6_service attribute to "false".

Note that when enable_dhcpv6_service is set to a defined value and override_denable_dhcpv6_service is set to "false", the last operation takes precedence. Thus the sequence $object->enable_dhcpv6_service("true"); $object->override_enable_dhcpv6_service("false"); will set override_enable_dhcpv6_service to "false", and the sequence $object->override_enable_dhcpv6_service("false"); $object->enable_dhcpv6_service("true"); will result in override_enable_dhcpv6_service="true".

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcpv6_service
my $enable_dhcpv6_service = $memberdhcp->enable_dhcpv6_service();
#Modify enable_dhcpv6_service
$memberdhcp->enable_dhcpv6_service("true");
```

enable_dhcp_on_lan2( )

Use this method to set or retrieve the enable_dhcp_on_lan2 value of a member. Set this value to enable/disable DHCP service on the LAN2 interface.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DHCP on the LAN2 interface or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp_on_lan2
my $enable_dhcp_on_lan2 = $memberdhcp->enable_dhcp_on_lan2();
#Modify enable_dhcp_on_lan2
$memberdhcp->enable_dhcp_on_lan2("true");
```

enable_dhcp_on_ipv6_lan2( )

Use this method to set or retrieve the enable_dhcp_on_ipv6_lan2 value of a member. Set this value to enable/disable DHCP service on the IPv6 LAN2 interface.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DHCP on the IPv6 LAN2 interface or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp_on_ipv6_lan2
my $enable_dhcp_on_ipv6_lan2 = $memberdhcp->enable_dhcp_on_ipv6_lan2();
#Modify enable_dhcp_on_ipv6_lan2
$memberdhcp->enable_dhcp_on_ipv6_lan2("true");
```

enable_dhcp_thresholds( )

Use this method to set or retrieve the enable_dhcp_thresholds value of a member DHCP server. Thresholds represents the watermarks above or below which address usage in a network is unexpected and might warrant your attention. This setting overrides the grid level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DHCP thresholds or "false" to disable them.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp_thresholds
my $enable_dhcp_thresholds = $memberdhcp->enable_dhcp_thresholds();
#Modify enable_dhcp_thresholds
$memberdhcp->enable_dhcp_thresholds("true");
```

enable_email_warnings( )

Use this method to set or retrieve the enable_email_warnings value of a member DHCP server. If we enable it and DHCP threshold is enabled, the Infoblox appliance sends an e-mail notification to an administrator if DHCP address usage crosses a high or low watermark threshold.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set enable_email_warnings flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_email_warnings
my $enable_email_warnings = $memberdhcp->enable_email_warnings();
#Modify enable_email_warnings
$memberdhcp->enable_email_warnings("true");
```

enable_fingerprint( )

Use this method to set or retrieve the member-level enable_fingerprint flag. If you enable this feature, the server will match a fingerprint for incoming lease requests.

Setting this method to a defined value implicitly sets the override_enable_fingerprint method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_enable_fingerprint attribute to "false".

Parameter

Specify "true" to set the enable_fingerprint flag or "false" to deactivate/unset it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_fingerprint
my $enable_fingerprint = $memberdhcp->enable_fingerprint();
#Modify enable_fingerprint
$memberdhcp->enable_fingerprint("false");
```

enable_gss_tsig( )

Use this method to set or retrieve the member-level enable_gss_tsig flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This is for DHCPv4 GSS-TSIG authentication.

Parameter

Specify "true" to enable GSS-TSIG authentication for DHCP IPv4 or "false" to disable it. The default value is undefined. Setting this flag overrides the enable_gss_tsig attribute of the grid.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_gss_tsig
my $enable_gss_tsig = $memberdhcp->enable_gss_tsig();
#Modify enable_gss_tsig
$memberdhcp->enable_gss_tsig("true");
```

enable_hostname_rewrite( )

Use this method to set or retrieve the grid member's enable_hostname_rewrite flag.

Parameter

Boolean to enable or disable hostname rewrite for the member. The default value is "false".

Cannot enable the hostname rewrite policy along with the Microsoft code page. See microsoft_code_page().

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_hostname_rewrite
$status = $memberdhcp->enable_hostname_rewrite();
#Modify enable_hostname_rewrite
$memberdhcp->enable_hostname_rewrite("true");
```

enable_ifmap( )

Use this method to enable or disable the IF-MAP DHCP client feature on this member. Enabling this feature requires a restart of DHCP services.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Boolean to enable or disable the IF-MAP client. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get IF-MAP enable value
my $ifmap_enabled = $memberdhcp->enable_ifmap();
#Enable IF-MAP Client feature
$memberdhcp->enable_ifmap("true");
```

enable_ifmap_publishing( )

Use this method to set or retrieve the ifmap publishing option of a DHCP Member object. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set ifmap publishing option or "false" to deactivate/unset it. The default value is 'false', which indicates that this attribute inherits the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ifmap_publishing
my $enable_ifmap_publishing = $memberdhcp->enable_ifmap_publishing()
# Modify enable_ifmap_publishing
$memberdhcp->enable_ifmap_publishing("true");
# Un-override enable_ifmap_publishing
$memberdhcp->enable_ifmap_publishing(undef);
```

enable_snmp_warnings( )

Use this method to set or retrieve the enable_snmp_warnings value of member DHCP server. When DHCP threshold is enabled and DHCP address usage crosses a watermark threshold, the appliance sends an SNMP trap to the trap receiver that you defined for the grid member level.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set enable_snmp_warnings flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_snmp_warnings
my $enable_snmp_warnings = $memberdhcp->enable_snmp_warnings();
#Modify enable_snmp_warnings
$memberdhcp->enable_snmp_warnings("true");
```

extattrs( )

Use this method to retrieve the extensible attributes associated with a Grid Member DHCP object. This attribute is read-only and cannot be set.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $memberdhcp->extattrs();
```

extensible_attributes( )

Use this method to retrieve the extensible attributes associated with a Grid Member DHCP object.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $memberdhcp->extensible_attributes();
```

gss_tsig_keys( )

Use this method to set or retrieve the list of GSS-TSIG keys for a member DHCPv4 object.

Setting this method to a defined value implicitly sets the override_gss_tsig_keys method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_gss_tsig_keys method to "false".

Note that when gss_tsig_keys is set to a defined value and override_gss_tsig_keys is set to "false", the last operation takes precedence. Thus the sequence $object->gss_tsig_keys($keys); $object->override_gss_tsig_keys("false"); will set override_gss_tsig_keys to "false", and the sequence $object->override_gss_tsig_keys("false"); $object->gss_tsig_keys($keys); will result in override_gss_tsig_keys="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::KerberosKey objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the Kerberos keys list
my $kerberos_keys_list = $member_dhcp->gss_tsig_keys();
```

```
#Modify the Kerberos keys list
my $kerberos_key1 = Infoblox::Cluster::KerberosKey->new(
       principal => 'host/appliance.ivan.test1@LADYBUG.LOCAL',
       );
my $kerberos_key2 = Infoblox::Cluster::KerberosKey->new(
       principal => 'host/appliance.ivan.test2@LADYBUG.LOCAL',
       );
$member_dhcp->gss_tsig_keys([$kerberos_key1, $kerberos_key2]);
```

high_water_mark( )

Use this method to set or retrieve the high_water_mark value of a member DHCP server. If the percent of allocated addresses exceeds this watermark, the appliance makes a syslog entry and if enabled, sends an e-mail notification.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number with the percentage value. Range is from 1 to 100. The high watermark value must be greater than the low watermark value. Default value is 95.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high_water_mark
my $high_water_mark = $memberdhcp->high_water_mark();
#Modify high_water_mark
$memberdhcp->high_water_mark(80);
```

high_water_mark_reset( )

Use this method to set or retrieve the high_water_mark_reset value of a member DHCP server. If the percentage of allocated addresses drops below this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number with the percentage value. Range is from 1 to 100. The high watermark value must be greater than the low watermark value. Default value is 85.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high_water_mark_reset
my $high_water_mark_reset = $memberdhcp->high_water_mark_reset();
#Modify high_water_mark_reset
$memberdhcp->high_water_mark_reset(80);
```

hostname_rewrite_policy( )

Use this method to set or retrieve the name of the hostname rewrite policy that is in the protocol_hostname_rewrite_policies array of the Grid DHCP object. This attribute is mandatory if enable_hostname_rewrite is "true".

Parameter

The name, in string format, of the hostname rewrite policy.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get hostname_rewrite_policy
```

```
my $name = $memberdhcp->hostname_rewrite_policy();
#Modify hostname_rewrite_policy
$memberdhcp->hostname_rewrite_policy('new_policy');
```

ifmap_client_credentials( )

Use this method to set the IF-MAP client credentials used by the DHCP IF-MAP client on this member.

Include the specified parameter to set the attribute value.

Parameter

IF-MAP client credentials. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Create new IF-MAP client credentials
my $credential = Infoblox::IFMap::Client::Credentials->new(
                                                            authentication => 'basic',
                                                            username       => 'something',
                                                            password       => 'else',
                                                           );

#Modify IF-MAP client credentials
$memberdhcp->ifmap_client_credentials($credentials);
```

ifmap_last_status_update( )

Use this method to get the last status update of the IF-MAP member.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get IF-MAP member last status update
$ifmap_last_status_update = $memberdhcp->ifmap_last_status_update();
```

ifmap_password( )

Use this method to set the IF-MAP client password used by the DHCP IF-MAP client on this member. The value can only be set or modified, but not retrieved. Note that use of this member has now been deprecated.

Include the specified parameter to set the attribute value.

Parameter

String for the IF-MAP client password. The default value is undef.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify IF-MAP client password
$memberdhcp->ifmap_password("secret");
```

ifmap_status( )

Use this method to get the IF-MAP member status.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get IF-MAP member status
$ifmap_status = $memberdhcp->ifmap_status();
```

ifmap_status_details( )

Use this method to get the status details of the IF-MAP member.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get IF-MAP member status details
$ifmap_status_details = $memberdhcp->ifmap_status_details();
```

ifmap_username( )

Use this method to set or retrieve the IF-MAP client username used by the DHCP IF-MAP client on this member. Note that use of this member has now been deprecated.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

String for the IF-MAP client username. The default value is undef.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get IF-MAP client username
my $username = $memberdhcp->ifmap_username();
#Modify IF-MAP client username
$memberdhcp->ifmap_username("ifmapclient");
```

ignore_id( )

Use this method to set or retrieve the ignore_id type of a grid member DHCP object. Indicates whether the appliance will ignore DHCP client IDs or MAC addresses. This setting overrides the upper-level settings.

Parameter

Valid values are 'NONE', 'CLIENT', or 'MACADDR'. The default is 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $memberdhcp->ignore_id();
# Modify attribute value
$memberdhcp->ignore_id('CLIENT');
#Un-override ignore_id
$memberdhcp->ignore_id(undef);
```

ignore_mac_addresses( )

Use this method to set or retrieve the ignore_mac_addresses list of a grid member DHCP object. A list of MAC addresses the appliance will ignore. This setting overrides the upper-level settings.

If you enter MAC addresses in the ignore_mac_addresses, then the appliance will ignore them. If you enter empty array, then the

appliance will ignore any MAC address.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $memberdhcp->ignore_mac_addresses();
# Modify attribute value
$memberdhcp->ignore_mac_addresses(["11::11::11::11::11::11"]);
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a grid member DHCP. If this flag is set to true all available DHCP options will be returned to the client.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $memberdhcp->ignore_dhcp_option_list_request();
#Modify ignore_dhcp_option_list_request
$memberdhcp->ignore_dhcp_option_list_request("false");
#Do not override ignore_dhcp_option_list_request
$memberdhcp->ignore_dhcp_option_list_request(undef);
```

ipv6_ddns_enable_option_fqdn( )

Use this method to set or retrieve the ipv6_ddns_enable_option_fqdn value of a member DHCP server. This method controls whether the FQDN option sent by the client is to be used, or if the server can automatically generate the FQDN.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_ddns_enable_option_fqdn method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_ipv6_ddns_enable_option_fqdn attribute to "false".

Note that when ipv6_ddns_enable_option_fqdn is set to a defined value and override_ipv6_ddns_enable_option_fqdn is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_ddns_enable_option_fqdn("true"); $object->override_ipv6_ddns_enable_option_fqdn("false"); will set override_ipv6_ddns_enable_option_fqdn to "false", and the sequence $object->override_ipv6_ddns_enable_option_fqdn("false"); $object->ipv6_ddns_enable_option_fqdn("true"); will result in override_ipv6_ddns_enable_option_fqdn="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that specifies the number of seconds the IP address for the name is cached. Default value is half of lease time.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_ddns_enable_option_fqdn
my $ipv6_ddns_enable_option_fqdn = $memberdhcp->ipv6_ddns_enable_option_fqdn();
#Modify ipv6_ddns_enable_option_fqdn
$memberdhcp->ipv6_ddns_enable_option_fqdn("true");
```

ipv6_ddns_server_always_updates( )

Use this method to set or retrieve the ipv6_ddns_server_always_updates flag. Set this flag to "false" to update DNS only if requested by the client.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_ddns_server_always_updates
my $ipv6_ddns_server_always_updates = $memberdhcp->ipv6_ddns_server_always_updates();
#Modify ipv6_ddns_server_always_updates
$memberdhcp->ipv6_ddns_server_always_updates("true");
```

ipv6_ddns_domainname( )

Use this method to set or retrieve the member IPv6 DDNS domain name value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_ddns_domainname attribute to "false".

Note that when ipv6_ddns_domainname is set to a defined value and override_dipv6_ddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_ddns_domainname("domain.com"); $object->override_ipv6_ddns_domainname("false"); will set override_ipv6_ddns_domainname to "false", and the sequence $object->override_ipv6_ddns_domainname("false"); $object->ipv6_ddns_domainname("domain.com"); will result in override_ipv6_ddns_domainname="true".

Parameter

The DDNS domain name in FQDN (Fully Qualified Domain Name) format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_ddns_domainname
my $ipv6_ddns_domainname = $memberdhcp->ipv6_ddns_domainname();
#Modify ipv6_ddns_domainname
$memberdhcp->ipv6_ddns_domainname("domain.com");
```

ipv6_ddns_hostname( )

Use this method to set or retrieve the member IPv6 DDNS hostname value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_ddns_hostname method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_ddns_hostname attribute to "false".

Note that when ipv6_ddns_hostname is set to a defined value and override_dipv6_ddns_hostname is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_ddns_hostname("host.com"); $object->override_ipv6_ddns_hostname("false"); will set override_ipv6_ddns_hostname to "false", and the sequence $object->override_ipv6_ddns_hostname("false"); $object->ipv6_ddns_hostname("host.com"); will result in override_ipv6_ddns_hostname="true".

Parameter

The DDNS hostname in FQDN (Fully Qualified Domain Name) format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_ddns_hostname
my $ipv6_ddns_hostname = $memberdhcp->ipv6_ddns_hostname();
#Modify ipv6_ddns_hostname
$memberdhcp->ipv6_ddns_hostname("host.com");
```

ipv6_ddns_ttl( )

Use this method to set or retrieve the member IPv6 DDNS TTL value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_ddns_ttl attribute to "false".

Note that when ipv6_ddns_ttl is set to a defined value and override_dipv6_ddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_ddns_ttl(12345); $object->override_ipv6_ddns_ttl("false"); will set override_ipv6_ddns_ttl to "false", and the sequence $object->override_ipv6_ddns_ttl("false"); $object->ipv6_ddns_ttl(12345); will result in override_ipv6_ddns_ttl="true".

Parameter

The preferred DDNS TTL value in seconds. The default is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_ddns_ttl
my $ipv6_ddns_ttl = $memberdhcp->ipv6_ddns_ttl();
#Modify ipv6_ddns_ttl
$memberdhcp->ipv6_ddns_ttl(12345);
```

ipv6_dns_update_style( )

Use this method to set or retrieve the update style for dynamic DNS updates (DHCPv6).

Setting this method to a defined value implicitly sets the override_ipv6_dns_update_style method to 'true'. Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_dns_update_style attribute to 'false'.

Note that when ipv6_dns_update_style is set to a defined value and override_ipv6_dns_update_style is set to 'false', the last operation takes precedence. Thus the sequence $object->ipv6_dns_update_style('INTERIM'); $object->override_ipv6_dns_update_style('false'); will set override_ipv6_dns_update_style to 'false', and the sequence $object->override_ipv6_dns_update_style('false'); $object->ipv6_dns_update_style('INTERIM'); will result in override_ipv6_dns_update_style='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are 'INTERIM' and 'STANDARD'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_dns_update_style value
my $value = $object->ipv6_dns_update_style();

#Modify ipv6_dns_update_style value
$object->ipv6_dns_update_style('STANDARD');
```

ipv6_domain_name( )

Use this method to set or retrieve the ipv6_domain_name value of a Grid Member DHCP object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_domain_name method to "true". Setting the parameter to

undefined causes the appliance to use the upper level default and automatically resets the override_ipv6_domain_name attribute to "false".

Note that when ipv6_domain_name is set to a defined value and override_ipv6_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_domain_name("testdomain"); $object->override_ipv6_domain_name("false"); will set override_ipv6_domain_name to "false", and the sequence $object->override_ipv6_domain_name("false"); $object->ipv6_domain_name("testdomain"); will result in override_ipv6_domain_name="true".

Parameter

The name of the client's domain for resolving names in DNS in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_domain_name
my $ipv6_domain_name = $memberdhcp->ipv6_domain_name();
#Modify ipv6_domain_name
$memberdhcp->ipv6_domain_name("test_domain.com");
```

ipv6_domain_name_servers( )

Use this method to set or retrieve the ipv6_domain_name_servers value of a Grid Member DHCP object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_ipv6_domain_name_servers attribute to "false".

Note that when ipv6_domain_name_servers is set to a defined value and override_ipv6_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_domain_name_servers("2001::1,2001::2"); $object->override_ipv6_domain_name_servers("false"); will set override_ipv6_domain_name_servers to "false", and the sequence $object->override_ipv6_domain_name_servers("false"); $object->ipv6_domain_name_servers("2001::1,2001::2"); will result in override_ipv6_domain_name_servers="true".

Parameter

The domain name server addresses in IPv6 address format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_domain_name_servers
my $ipv6_domain_name_servers = $memberdhcp->ipv6_domain_name_servers();
#Modify ipv6_domain_name_servers
$memberdhcp->ipv6_domain_name_servers("2001::1,2001::2");
```

ipv6_enable_ddns( )

Use this method to set or retrieve the ipv6_enable_ddns flag. Set this flag to enable DHCPv6 dynamic updates.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_enable_ddns method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_enable_ddns attribute to "false".

Note that when ipv6_enable_ddns is set to a defined value and override_dipv6_enable_ddns is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_enable_ddns("true"); $object->override_ipv6_enable_ddns("false"); will set override_ipv6_enable_ddns to "false", and the sequence $object->override_ipv6_enable_ddns("false"); $object->ipv6_enable_ddns("true"); will result in override_ipv6_enable_ddns="true".

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_enable_ddns
my $ipv6_enable_ddns = $memberdhcp->ipv6_enable_ddns();
#Modify ipv6_enable_ddns
$memberdhcp->ipv6_enable_ddns("true");
```

ipv6_enable_gss_tsig( )

Use this method to set or retrieve the member-level ipv6_enable_gss_tsig flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This is for DHCPv6 GSS-TSIG authentication.

Setting this method to a defined value implicitly sets the override_ipv6_enable_gss_tsig method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_ipv6_enable_gss_tsig attribute to "false".

Note that when ipv6_enable_gss_tsig is set to a defined value and override_ipv6_enable_gss_tsig is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_enable_gss_tsig("true"); $object->override_ipv6_enable_gss_tsig("false"); will set override_ipv6_enable_gss_tsig to "false", and the sequence $object->override_ipv6_enable_gss_tsig("false"); $object->ipv6_enable_gss_tsig("true"); will result in override_ipv6_enable_gss_tsig="true".

Parameter

Specify "true" to enable GSS-TSIG authentication for DHCP IPv6 or "false" to disable it. The default value is undefined. Setting this flag overrides the ipv6_enable_gss_tsig attribute of the grid.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_enable_gss_tsig
my $ipv6_enable_gss_tsig = $memberdhcp->ipv6_enable_gss_tsig();
#Modify ipv6_enable_gss_tsig
$memberdhcp->ipv6_enable_gss_tsig("true");
```

ipv6_enable_lease_scavenge( )

Use this method to set or retrieve the flag that indicates whether the DHCPv6 lease scavenging is enabled or disabled.

Setting this method to a defined value implicitly sets the override_ipv6_lease_scavenge method to "true". When you set the parameter to undefined and if ipv6_lease_scavenge_time or ipv6_remember_expired_client_association are defined, the appliance uses the default Grid value and automatically resets override_ipv6_lease_scavenge attribute to "false".

Note that when ipv6_enable_lease_scavenge is set to a defined value and override_ipv6_enable_lease_scavenge is set to "false", the last operation takes precedence. Thus, the sequence $object->ipv6_enable_lease_scavenge("true"); $object->override_ipv6_lease_scavenge("false"); sets override_ipv6_lease_scavenge to "false", and the sequence $object->override_ipv6_lease_scavenge("false"); $object->ipv6_enable_lease_scavenge("true"); results in override_ipv6_lease_scavenge="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DHCPv6 lease scavenging and 'false' to disable it. The default value is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_enable_lease_scavenge
my $ipv6_enable_lease_scavenge = $memberdhcp->ipv6_enable_lease_scavenge();
#Modify ipv6_enable_lease_scavenge
$memberdhcp->ipv6_enable_lease_scavenge("true");
```

ipv6_remember_expired_client_association( )

Use this method to set or retrieve the flag that indicates whether the DHCPv6 expired lease binding is enabled or disabled.

Setting this method to a defined value implicitly sets the override_ipv6_lease_scavenge method to "true". When you set the parameter to undefined and if ipv6_enable_lease_scavenge or ipv6_lease_scavenge_time are defined, the appliance uses the default Grid value and automatically resets override_ipv6_lease_scavenge to "false".

Note that when ipv6_remember_expired_client_association is set to a defined value and override_ipv6_lease_scavenge is set to "false", the last operation takes precedence. Thus, the sequence $object->ipv6_remember_expired_client_association("true"); $object->override_ipv6_lease_scavenge("false"); sets override_ipv6_lease_scavenge to "false", and the sequence $object->override_ipv6_lease_scavenge("false"); $object->ipv6_remember_expired_client_association("true"); results in override_ipv6_lease_scavenge="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the DHCPv6 server to 'remember' the client and 'false' to disable it. The default value is false.

Returns

If you specified a parameter, the method returns true when the modification succeds, and return false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_remember_expired_client_association
my $ipv6_remember_expired_client_association = $memberdhcp-
>ipv6_remember_expired_client_association();
#Modify ipv6_remember_expired_client_association
$memberdhcp->ipv6_remember_expired_client_association("true");
```

ipv6_enable_retry_updates( )

Use this method to set or retrieve the ipv6_enable_retry_updates flag. If this flag is set to "true", the DHCPv6 server retries failed dynamic DNS updates.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_enable_retry_updates method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_enable_retry_updates attribute to "false".

Note that when ipv6_enable_retry_updates is set to a defined value and override_dipv6_enable_retry_updates is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_enable_retry_updates("true"); $object->override_ipv6_enable_retry_updates("false"); will set override_ipv6_enable_retry_updates to "false", and the sequence $object->override_ipv6_enable_retry_updates("false"); $object->ipv6_enable_retry_updates("true"); will result in override_ipv6_enable_retry_updates="true".

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_enable_retry_updates
my $ipv6_enable_retry_updates = $memberdhcp->ipv6_enable_retry_updates();
#Modify ipv6_enable_retry_updates
$memberdhcp->ipv6_enable_retry_updates("true");
```

ipv6_generate_hostname( )

Use this method to set or retrieve the ipv6_generate_hostname flag. Set this flag to generate the hostname if it is not sent by the client.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_generate_hostname method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_generate_hostname attribute to "false".

Note that when ipv6_generate_hostname is set to a defined value and override_dipv6_generate_hostname is set to "false", the last

operation takes precedence. Thus the sequence $object->ipv6_generate_hostname("true"); $object->override_ipv6_generate_hostname("false"); will set override_ipv6_generate_hostname to "false", and the sequence $object->override_ipv6_generate_hostname("false"); $object->ipv6_generate_hostname("true"); will result in override_ipv6_generate_hostname="true".

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_generate_hostname
my $ipv6_generate_hostname = $memberdhcp->ipv6_generate_hostname();
#Modify ipv6_generate_hostname
$memberdhcp->ipv6_generate_hostname("true");
```

ipv6_gss_tsig_keys( )

Use this method to set or retrieve the list of GSS-TSIG keys for a member DHCPv6 object.

Setting this method to a defined value implicitly sets the override_ipv6_gss_tsig_keys method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_gss_tsig_keys method to "false".

Note that when ipv6_gss_tsig_keys is set to a defined value and override_ipv6_gss_tsig_keys is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_gss_tsig_keys($keys); $object->override_ipv6_gss_tsig_keys("false"); will set override_ipv6_gss_tsig_keys to "false", and the sequence $object->override_ipv6_gss_tsig_keys("false"); $object->ipv6_gss_tsig_keys($keys); will result in override_ipv6_gss_tsig_keys="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::KerberosKey objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the Kerberos keys list
my $kerberos_keys_list = $member_dhcp->ipv6_gss_tsig_keys();

#Modify the Kerberos keys list
my $kerberos_key1 = Infoblox::Cluster::KerberosKey->new(
       principal => 'host/appliance.ivan.test1@LADYBUG.LOCAL',
       );
my $kerberos_key2 = Infoblox::Cluster::KerberosKey->new(
       principal => 'host/appliance.ivan.test2@LADYBUG.LOCAL',
       );
$member_dhcp->ipv6_gss_tsig_keys([$kerberos_key1, $kerberos_key2]);
```

ipv6_kdc_server( )

Use this method to specify or retrieve the IPv4 address or FQDN of the Kerberos server for DHCPv6 GSS-TSIG authentication. This setting overrides the grid-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The Kerberos server IPv4 address or hostname, with a maximum of 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_kdc_server
my $ipv6_kdc_server = $memberdhcp->ipv6_kdc_server();
#Modify ipv6_kdc_server
$memberdhcp->ipv6_kdc_server("10.32.0.8");
```

ipv6_lease_scavenge_time( )

Use this method to set or retrieve the Grid-level grace period in seconds to keep an expired lease before it gets deleted by the scavenging process.

Setting this method to a defined value implicitly sets the override_ipv6_lease_scavenge method to "true". When you set the parameter to undefined and if ipv6_enable_lease_scavenge or ipv6_remember_expired_client_association are defined, the appliance uses the default Grid value and automatically resets override_ipv6_lease_scavenge attribute to "false".

Note that when ipv6_lease_scavenge_time is set to a defined value and override_ipv6_enable_lease_scavenge is set to "false", the last operation takes precedence. Thus, the sequence $object->ipv6_lease_scavenge_time(32000); $object->override_ipv6_lease_scavenge("false"); sets override_ipv6_lease_scavenge to "false", and the sequence $object->override_ipv6_lease_scavenge("false"); $object->ipv6_lease_scavenge_time(32000); results in override_ipv6_lease_scavenge="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer greater than or equal to 21600.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_lease_scavenge_time
my $ipv6_lease_scavenge_time = $griddhcp->ipv6_lease_scavenge_time();
#Modify ipv6_lease_scavenge_time
```

ipv6_microsoft_code_page( )

Use this method to set or retrieve the Microsoft client DHCP IPv6 code page value of a grid member. This value is the hostname translation code page for Microsoft DHCP IPv6 clients and overrides the grid-level Microsoft DHCP IPv6 client code page.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_microsoft_code_page method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_microsoft_code_page attribute to "false".

Note that when ipv6_microsoft_code_page is set to a defined value and override_dipv6_microsoft_code_page is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_microsoft_code_page("Cyrillic (ISO-5589-5)"); $object->override_ipv6_microsoft_code_page("false"); will set override_ipv6_microsoft_code_page to "false", and the sequence $object->override_ipv6_microsoft_code_page("false"); $object->ipv6_microsoft_code_page("Cyrillic (ISO-5589-5)"); will result in override_ipv6_microsoft_code_page="true".

Parameter

Microsoft DHCP client code page in string format. Valid values are:

None

Arabic (1256)

Arabic (ISO-8859-6)

Baltic (1257)

Baltic (775)

Baltic (ISO-8859-4)

Central Europe (1250)

Turkish (ISO-8859-9)

US (437)

Vietnam (1258)

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_microsoft_code_page
my $ipv6_microsoft_code_page = $memberdhcp->ipv6_microsoft_code_page();
#Modify ipv6_microsoft_code_page
$memberdhcp->ipv6_microsoft_code_page("Cyrillic (ISO-8859-5)");
#Do not override ipv6_microsoft_code_page
$memberdhcp->ipv6_microsoft_code_page("None");
```

ipv6_options( )

Use this method to set or retrieve the ipv6 options.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_options method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_options attribute to "false".

Note that when ipv6_options is set to a defined value and override_dipv6_options is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_options([$opt]); $object->override_ipv6_options("false"); will set override_ipv6_options to "false", and the sequence $object->override_ipv6_options("false"); $object->ipv6_options([$opt]); will result in override_ipv6_options="true".

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_options
my $ipv6_options = $memberdhcp->ipv6_options();
#Modify ipv6_options
my $option1 = Infoblox::DHCP::Option->new(
    name   => "dhcp6.rapid-commit",
    value  => "true"
);
$memberdhcp->ipv6_options([$option1);
```

ipv6_recycle_leases( )

Use this method to set or retrieve the ipv6_recycle_leases flag of the DHCP member.

If the flag is enabled, the leases are kept in recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Setting this method to a defined value implicitly sets the override_ipv6_recycle_leases method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_recycle_leases attribute to "false".

Note that when ipv6_recycle_leases is set to a defined value and override_ipv6_recycle_leases is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_recycle_leases("true"); $object->override_ipv6_recycle_leases("false"); will set override_ipv6_recycle_leases to "false", and the sequence $objct->override_ipv6_recycle_leases("false"); $object->ipv6_recycle_leases("true"); will result in override_ipv6_recycle_leases="true".

Parameter

Specify "true" to set the ipv6_recycle_leases flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_recycle_leases
my $ipv6_recycle_leases = $memberdhcp->ipv6_recycle_leases();
#Modify ipv6_recycle_leases
$memberdhcp->ipv6_recycle_leases("false");
```

ipv6_retry_updates_interval( )

Use this method to set or retrieve the ipv6_retry_updates_interval value. Set the retry interval when the member DHCPv6 server makes repeated attempts to send DDNS updates to a DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the retry interval in minutes. The default retry interval is five minutes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_retry_updates_interval
my $ipv6_retry_updates_interval = $memberdhcp->ipv6_retry_updates_interval();
#Modify ipv6_retry_updates_interval
$memberdhcp->ipv6_retry_updates_interval(10);
```

ipv6_server_duid( )

Use this method to set or retrieve the server DHCPv6 unique identifier (DUID) for the grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

DUID of the grid member in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_server_duid
my $ipv6_server_duid = $memberdhcp->ipv6_server_duid();
#Modify ipv6_server_duid
$memberdhcp->ipv6_server_duid("false");
```

ipv6_update_dns_on_lease_renewal( )

Use this method to set or retrieve the ipv6_update_dns_on_lease_renewal flag. This attribute controls whether the DHCP server updates DNS when an IPv6 DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ipv6_update_dns_on_lease_renewal attribute to "false".

Note that when ipv6_update_dns_on_lease_renewal is set to a defined value and override_dipv6_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_update_dns_on_lease_renewal("true"); $object->override_ipv6_update_dns_on_lease_renewal("false"); will set override_ipv6_update_dns_on_lease_renewal to "false", and the sequence $object->override_ipv6_update_dns_on_lease_renewal("false"); $object->ipv6_update_dns_on_lease_renewal("true"); will result in override_ipv6_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_update_dns_on_lease_renewal
my $ipv6_update_dns_on_lease_renewal = $memberdhcp->ipv6_update_dns_on_lease_renewal();
#Modify ipv6_update_dns_on_lease_renewal
$memberdhcp->ipv6_update_dns_on_lease_renewal("true");
```

kdc_server( )

Use this method to specify or retrieve the IPv4 address or FQDN of the Kerberos server for DHCPv4 GSS-TSIG authentication. This setting overrides the grid-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The Kerberos server IPv4 address or FQDN, with a maximum of 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get kdc_server
my $kdc_server = $memberdhcp->kdc_server();
#Modify  kdc_server
$memberdhcp->kdc_server("10.32.0.7");
```

ipv6_lease_scavenge_time( )

Use this method to set or retrieve the member-level grace period in seconds to keep an expired lease before it gets deleted by the scavenging process.

Setting this method to a defined value implicitly sets the override_ipv6_lease_scavenge method to "true". Setting the parameter to undefined unless ipv6_enable_lease_scavenge is defined causes the appliance to use the Grid default and automatically resets the override_ipv6_lease_scavenge attribute to "false".

Note that when ipv6_lease_scavenge_time is set to a defined value and override_dipv6_lease_scavenge_time is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_lease_scavenge_time("true"); $object->override_ipv6_lease_scavenge("false"); will set override_ipv6_lease_scavenge to "false", and the sequence $object->override_ipv6_lease_scavenge("false"); $object->ipv6_lease_scavenge_time("true"); will result in override_ipv6_lease_scavenge="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer greater than or equal to 21600.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_lease_scavenge_time
my $ipv6_lease_scavenge_time = $memberdhcp->ipv6_lease_scavenge_time();
#Modify ipv6_lease_scavenge_time
$memberdhcp->ipv6_lease_scavenge_time("22000");
```

lease_per_client_settings( )

Use this method to set or retrieve the Grid member setting that defines how DHCP server will free or release client leases.

Setting this method to a defined value implicitly sets the override_lease_per_client_settings method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_lease_per_client_settings attribute to "false".

Note that when lease_per_client_settings is set to a defined value and override_lease_per_client_settings is set to "false", the last operation takes precedence. Thus the sequence $object->lease_per_client_settings("NEVER_RELEASE"); $object->override_lease_per_client_settings("false"); will set override_lease_per_client_settings to "false", and the sequence $object->override_lease_per_client_settings("false"); $object->lease_per_client_settings("NEVER_RELEASE"); will set override_lease_per_client_settings to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'ONE_LEASE_PER_CLIENT', 'RELEASE_MATCHING_ID' and 'NEVER_RELEASE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lease_per_client_settings value
my $lease_per_client_settings = $object->lease_per_client_settings();

#Modify lease_per_client_settings value
$object->lease_per_client_settings("NEVER_RELEASE");
```

lease_scavenge_time( )

Use this method to set or retrieve the member-level lease_scavenge_time value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_lease_scavenge_time method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_lease_scavenge_time attribute to "false".

Note that when lease_scavenge_time is set to a defined value and override_lease_scavenge_time is set to "false", the last operation takes precedence. Thus the sequence $object->lease_scavenge_time(604800); $object->override_lease_scavenge_time("false"); will set override_lease_scavenge_time to "false", and the sequence $object->override_lease_scavenge_time("false"); $object->lease_scavenge_time(604800); will result in override_lease_scavenge_time="true".

Parameter

An integer that specifies the period of time, in seconds, that free and backup leases remain in the database before they are automatically deleted. To disable lease scavenging, set the parameter to -1. The minimum positive value must be greater than 86400 seconds (1 day). The default value of this parameter is -1, which means that lease scavenging is disabled.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lease_scavenge_time
my $lease_scavenge = $memberdhcp->lease_scavenge_time();
#Modify lease_scavenge_time
$memberdhcp->lease_scavenge_time(30 * 24 * 60 * 60);
```

log_lease_events( )

Use this method to set or retrieve the log_lease_events value of a member DHCP server. This value specifies whether the grid member logs lease events.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_log_lease_events method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_log_lease_events attribute to "false".

Note that when log_lease_events is set to a defined value and override_dlog_lease_events is set to "false", the last operation takes precedence. Thus the sequence $object->log_lease_events("true"); $object->override_log_lease_events("false"); will set override_log_lease_events to "false", and the sequence $object->override_log_lease_events("false"); $object->log_lease_events("true"); will result in override_log_lease_events="true".

Parameter

Specify "true" to set log_lease_events flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get log_lease_events
my $log_lease_events = $memberdhcp->log_lease_events();
#Modify log_lease_events
$memberdhcp->log_lease_events("true");
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the Member DHCP.

Filters are used to screen address assignments on a Member DHCP if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $memberdhcp->logic_filters();
#Modify logic_filters
$memberdhcp->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an Infoblox::DHCP::Filter::MAC,
Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

low_water_mark( )

Use this method to set or retrieve the low_water_mark value of a member DHCP server. If the percent of allocated addresses drops below this watermark, the appliance makes a syslog entry and if enabled, sends an e-mail notification.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number with the percentage value. Range is from 0 to 100. The low watermark value must be lower than the high watermark value. The default low watermark number is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low_water_mark
my $low_water_mark = $memberdhcp->low_water_mark();
#Modify low_water_mark
$memberdhcp->low_water_mark(10);
```

low_water_mark_reset( )

Use this method to set or retrieve the low_water_mark_reset value of a member DHCP server. If the percentage of allocated addresses exceeds this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number with the percentage value. Range is from 0 to 100. The low watermark reset value must be higher than the low watermark value. The default low watermark reset value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low_water_mark_reset
my $low_water_mark_reset = $memberdhcp->low_water_mark_reset();
#Modify low_water_mark_reset
$memberdhcp->low_water_mark_reset(10);
```

override_dns_update_style( )

The override_dns_update_style controls whether the dns_update_style in the DHCP Member is used, instead of the Grid default.

The override_dns_update_style can be specified explicitly. It is also set implicitly when dns_update_style is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to 'true' to override the Grid-level setting for dns_update_style. Set the parameter to 'false' to inherit the Grid-level setting for dns_update_style.

The default value of this parameter is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_dns_update_style value
my $value = $object->override_dns_update_style();

#Modify override_dns_update_style value
$object->override_dns_update_style('true');
```

override_enable_ifmap_publishing( )

The override_enable_ifmap_publishing controls whether the enable_ifmap_publishing in the DHCP Member is used, instead of the Grid default.

The override_enable_ifmap_publishing can be specified explicitly. It is also set implicitly when enable_ifmap_publishing is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ifmap_publishing. Set the parameter to "false" to inherit the grid-level setting for enable_ifmap_publishing.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_ifmap_publishing
my $override_enable_ifmap_publishing=$memberdhcp->override_enable_ifmap_publishing( );
#Modifying override_enable_ifmap_publishing
$memberdhcp->override_enable_ifmap_publishing("true");
```

override_gss_tsig_keys( )

The override_gss_tsig_keys attribute controls whether the gss_tsig_keys method values of the member are used, instead of the Grid default.

The override_gss_tsig_keys attribute can be specified explicitly. It is also set implicitly when gss_tsig_keys is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override GSS-TSIG keys. Set the parameter to "false" to inherit the grid-level GSS-TSIG keys.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_gss_tsig_keys
my $override_gss_tsig_keys = $member_dhcp->override_gss_tsig_keys();
#Modyfying override_gss_tsig_keys
$member_dhcp->override_gss_tsig_keys("true");
```

override_ipv6_dns_update_style( )

The override_ipv6_dns_update_style controls whether the ipv6_dns_update_style is used instead of the Grid default in the DHCP member.

The override_ipv6_dns_update_style can be specified explicitly. It is also set implicitly when ipv6_dns_update_style is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to 'true' to override the Grid-level setting for ipv6_dns_update_style. Set the parameter to 'false' to inherit the Grid-level setting for ipv6_dns_update_style.

The default value of this parameter is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ipv6_dns_update_style value
my $value = $object->override_ipv6_dns_update_style();

#Modify override_ipv6_dns_update_style value
$object->override_ipv6_dns_update_style('true');
```

override_ipv6_gss_tsig_keys( )

The override_ipv6_gss_tsig_keys attribute controls whether the ipv6_gss_tsig_keys method values of the member are used, instead of the Grid default.

The override_ipv6_gss_tsig_keys attribute can be specified explicitly. It is also set implicitly when ipv6_gss_tsig_keys is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override GSS-TSIG keys. Set the parameter to "false" to inherit the grid-level GSS-TSIG keys.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_gss_tsig_keys
my $override_ipv6_gss_tsig_keys = $member_dhcp->override_ipv6_gss_tsig_keys();
#Modyfying override_ipv6_gss_tsig_keys
$member_dhcp->override_ipv6_gss_tsig_keys("true");
```

override_ipv6_lease_scavenge( )

The override_ipv6_lease_scavenge attribute controls whether the ipv6_enable_lease_scavenge, ipv6_lease_scavenge_time and ipv6_remember_expired_client_association methods values of the member are used, instead of the Grid default.

The override_ipv6_lease_scavenge attribute can be specified explicitly. It is also set implicitly when one of ipv6_enable_lease_scavenge, ipv6_lease_scavenge_time and ipv6_remember_expired_client_association is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override settings for scavenging of DHCPv6 leases. Set the parameter to "false" to inherit settings for scavenging of DHCPv6 leases.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_lease_scavenge
my $override_ipv6_lease_scavenge = $memberdhcp->override_ipv6_lease_scavenge();
#Modyfying override_ipv6_lease_scavenge
$memberdhcp->override_ipv6_lease_scavenge("true");
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value of the Member DHCP is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$memberdhcp->override_logic_filters( );
#Modifying override_logic_filters
$memberdhcp->override_logic_filters("true");
```

name( )

Use this method to retrieve the grid name.

Parameter

None.

Returns

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $memberdhcp->name();
```

nextserver( )

Use this method to set or retrieve the next server value of a member DHCP server. This value is the IP address or name of the boot file server on which the boot file is stored.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::Grid::Member::DHCP->bootfile() and Infoblox::Grid::Member::DHCP->bootserver().

Parameter

The boot file server IP address or name in FQDN format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot file server name can have a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nextserver
my $nextserver = $memberdhcp->nextserver();
#Modify nextserver
$memberdhcp->nextserver("1.1.1.1");
#Un-override nextserver
$memberdhcp->nextserver(undef);
```

microsoft_code_page( )

Use this method to set or retrieve the Microsoft client DHCP IPv4 code page value of a grid member. This value is the hostname translation code page for Microsoft DHCP IPv4 clients and overrides the grid-level Microsoft DHCP IPv4 client code page.

Setting microsoft_code_page() to undef removes the override, enabling the appliance to use the grid-level microsoft_code_page setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Microsoft DHCP client code page in string format. Valid values are the same as those for ipv6_microsoft_code_page. See ipv6_microsoft_code_page().

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get microsoft_code_page
my $microsoft_code_page = $memberdhcp->microsoft_code_page();
#Modify microsoft_code_page
$memberdhcp->microsoft_code_page("Cyrillic (ISO-8859-5)");
#Do not override microsoft_code_page
$memberdhcp->microsoft_code_page("None");
```

options( )

Use this method to set or retrieve the options value of a member DHCP server. DHCP options provide network configuration settings and various services available on the network for DHCP member. This setting overrides the grid level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $memberdhcp->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name  => "lease-time",
    value => 50
);

my $option2 = Infoblox::DHCP::Option->new(
    name  => "routers",
    value => "1.4.1.1, 2.2.2.2"
);

my $option3 = Infoblox::DHCP::Option->new(
    name  => "nameservers",
    value => "1.1.1.1, 2.2.2.2"
);

my $option4 = Infoblox::DHCP::Option->new(
    name  => "domain-name",
    value => "domainname.com",
);

my $option5 = Infoblox::DHCP::Option->new(
    name  => "broadcast",
    value => "255.0.0.0",
);

$memberdhcp->options([$option1, $option2, $option3, $option4, $option5]);
```

option60_match_rules( )

Use this method to set or retrieve the option60_match_rules value of a member DHCP server. An Option60MatchRule object allows specifying match rules for Option 60 globally. This setting overrides the grid level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option60MatchRule object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get option60_match_rules
my $options = $memberdhcp->option60_match_rules();
#Modify option60_match_rules
my $option60_match_rule = Infoblox::DHCP::Option60MatchRule->new(
                                  "option_space" => "infospace",
                                  "match_value" => "Nortel-i2004-A",
                                  "is_substring" => "true",
                                  "substring_offset" => "8",
                                  "substring_length" => "14"
                                );

$memberdhcp->option60_match_rules([$option60_match_rule]);
#Do not override option60_match_rules
$memberdhcp->option60_match_rules(undef);
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the member DHCP server is used, instead of the Grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_ttl. Set the parameter to "false" to inherit the grid-level setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_ttl
my $override_ddns_ttl=$memberdhcp->override_ddns_ttl( );
#Modifying override_ddns_ttl
$memberdhcp->override_ddns_ttl("true");
```

override_enable_dhcpv6_service( )

The override_enable_dhcpv6_service attribute controls whether the enable_dhcpv6_service value in the DHCP member is used, instead of the Grid default.

The override_enable_dhcpv6_service attribute can be specified explicitly. It is also set implicitly when enable_dhcpv6_service is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_dhcpv6_service. Set the parameter to "false" to inherit the grid-level setting for enable_dhcpv6_service.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_dhcpv6_service
my $override_enable_dhcpv6_service=$memberdhcp->override_enable_dhcpv6_service( );
#Modifying override_enable_dhcpv6_service
$memberdhcp->override_enable_dhcpv6_service("true");
```

override_enable_fingerprint( )

Use this method to set or retrieve the override_enable_fingerprint flag.

Parameter

Boolean to enable or disable the override fibgerprint flag for the member. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_fingerprint
my $status = $memberdhcp->override_enable_fingerprint();
#Modify override_enable_fingerprint
$memberdhcp->override_enable_fingerprint("true");
```

override_hostname_rewrite( )

Use this method to set or retrieve the override_hostname_rewrite flag.

Parameter

Boolean to enable or disable the override hostname rewrite policy flag for the member. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_hostname_rewrite
my $status = $memberdhcp->override_hostname_rewrite();
#Modify override_hostname_rewrite
$memberdhcp->override_hostname_rewrite("true");
```

override_ignore_id( )

The override_ignore_id controls whether the ignore_id in the DHCP member is used, instead of the grid-level default.

The override_ignore_id can be specified explicitly. It is also set implicitly when ignore_id is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ignore_id and ignore_mac_addresses. Set the parameter to "false" to inherit the grid-level setting for ignore_id and ignore_mac_addresses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$memberdhcp->override_ignore_id();
#Modifying attribute value
$memberdhcp->override_ignore_id('true');
```

override_ipv6_ddns_domainname( )

The override_ipv6_ddns_domainname attribute controls whether the ipv6_ddns_domainname value in the DHCP member is used, instead

of the Grid default.

The override_ipv6_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ipv6_ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ipv6_ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_ddns_domainname
my $override_ipv6_ddns_domainname=$memberdhcp->override_ipv6_ddns_domainname( );
#Modifying override_ipv6_ddns_domainname
$memberdhcp->override_ipv6_ddns_domainname("true");
```

override_ipv6_ddns_hostname( )

The override_ipv6_ddns_hostname attribute controls whether the ipv6_ddns_hostname value in the DHCP member is used, instead of the Grid default.

The override_ipv6_ddns_hostname attribute can be specified explicitly. It is also set implicitly when ipv6_ddns_hostname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_ddns_hostname. Set the parameter to "false" to inherit the grid-level setting for ipv6_ddns_hostname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_ddns_hostname
my $override_ipv6_ddns_hostname=$memberdhcp->override_ipv6_ddns_hostname( );
#Modifying override_ipv6_ddns_hostname
$memberdhcp->override_ipv6_ddns_hostname("true");
```

override_ipv6_ddns_enable_option_fqdn( )

Use this method to set or retrieve the override_ipv6_ddns_enable_option_fqdn value of a Grid Member DHCP object.

The override_ipv6_ddns_enable_option_fqdn attribute can be specified explicitly. It is also set implicitly when ipv6_ddns_enable_option_fqdn is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipv6_ddns_enable_option_fqdn. Set the parameter to "false" to inherit the upper-level setting for ipv6_ddns_enable_option_fqdn.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ipv6_ddns_enable_option_fqdn
my $override_ipv6_ddns_enable_option_fqdn = $memberdhcp->override_ipv6_ddns_enable_option_fqdn();
#Modify override_ipv6_ddns_enable_option_fqdn
$memberdhcp->override_ipv6_ddns_enable_option_fqdn("true");
```

override_ipv6_ddns_ttl( )

The override_ipv6_ddns_ttl attribute controls whether the ipv6_ddns_ttl value in the DHCP member is used, instead of the Grid default.

The override_ipv6_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ipv6_ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_ddns_ttl. Set the parameter to "false" to inherit the grid-level setting for ipv6_ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_ddns_ttl
my $override_ipv6_ddns_ttl=$memberdhcp->override_ipv6_ddns_ttl( );
#Modifying override_ipv6_ddns_ttl
$memberdhcp->override_ipv6_ddns_ttl("true");
```

override_ipv6_domain_name( )

Use this method to set or retrieve the override_ipv6_domain_name value of a Grid Member DHCP object.

The override_ipv6_domain_name attribute can be specified explicitly. It is also set implicitly when ipv6_domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipv6_domain_name. Set the parameter to "false" to inherit the upper-level setting for ipv6_domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ipv6_domain_name
my $override_ipv6_domain_name = $memberdhcp->override_ipv6_domain_name();
#Modify override_ipv6_domain_name
$memberdhcp->override_ipv6_domain_name("true");
```

override_ipv6_domain_name_servers( )

Use this method to set or retrieve the override_ipv6_domain_name_servers value of a Grid Member DHCP object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipv6_domain_name_servers. Set the parameter to "false" to inherit the upper-level setting for ipv6_domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ipv6_domain_name_servers
my $override_ipv6_domain_name_servers = $memberdhcp->override_ipv6_domain_name_servers();
#Modify override_ipv6_domain_name_servers
$memberdhcp->override_ipv6_domain_name_servers("true");
```

override_ipv6_enable_ddns( )

The override_ipv6_enable_ddns attribute controls whether the ipv6_enable_ddns value in the DHCP member is used, instead of the Grid default.

The override_ipv6_enable_ddns attribute can be specified explicitly. It is also set implicitly when ipv6_enable_ddns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_enable_ddns. Set the parameter to "false" to inherit the grid-level setting for ipv6_enable_ddns.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_enable_ddns
my $override_ipv6_enable_ddns=$memberdhcp->override_ipv6_enable_ddns( );
#Modifying override_ipv6_enable_ddns
$memberdhcp->override_ipv6_enable_ddns("true");
```

override_ipv6_enable_gss_tsig( )

The override_ipv6_enable_gss_tsig attribute controls whether the ipv6_enable_gss_tsig value in the DHCP member is used, instead of the Grid default.

The override_ipv6_enable_gss_tsig attribute can be specified explicitly. It is also set implicitly when ipv6_enable_gss_tsig is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_enable_gss_tsig. Set the parameter to "false" to inherit the grid-level setting for ipv6_enable_gss_tsig.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_enable_gss_tsig
my $override_ipv6_enable_gss_tsig=$memberdhcp->override_ipv6_enable_gss_tsig( );
#Modifying override_ipv6_enable_gss_tsig
$memberdhcp->override_ipv6_enable_gss_tsig("true");
```

override_ipv6_enable_retry_updates( )

The override_ipv6_enable_retry_updates attribute controls whether the ipv6_enable_retry_updates value of the DHCP member is used, instead of the Grid default.

The override_ipv6_enable_retry_updates attribute can be specified explicitly. It is also set implicitly when ipv6_enable_retry_updates is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_enable_retry_updates. Set the parameter to "false" to inherit the grid-level setting for ipv6_enable_retry_updates.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_enable_retry_updates
my $override_ipv6_enable_retry_updates=$memberdhcp->override_ipv6_enable_retry_updates( );
#Modifying override_ipv6_enable_retry_updates
$memberdhcp->override_ipv6_enable_retry_updates("true");
```

override_ipv6_generate_hostname( )

The override_ipv6_generate_hostname attribute controls whether the ipv6_generate_hostname value in the DHCP member is used, instead of the Grid default.

The override_ipv6_generate_hostname attribute can be specified explicitly. It is also set implicitly when ipv6_generate_hostname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_generate_hostname. Set the parameter to "false" to inherit the grid-level setting for ipv6_generate_hostname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_generate_hostname
my $override_ipv6_generate_hostname=$memberdhcp->override_ipv6_generate_hostname( );
#Modifying override_ipv6_generate_hostname
$memberdhcp->override_ipv6_generate_hostname("true");
```

override_ipv6_microsoft_code_page( )

The override_ipv6_microsoft_code_page attribute controls whether the ipv6_microsoft_code_page value in the DHCP member is used, instead of the Grid default.

The override_ipv6_microsoft_code_page attribute can be specified explicitly. It is also set implicitly when ipv6_microsoft_code_page is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_microsoft_code_page. Set the parameter to "false" to inherit the grid-level setting for ipv6_microsoft_code_page.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_microsoft_code_page
my $override_ipv6_microsoft_code_page=$memberdhcp->override_ipv6_microsoft_code_page( );
```

```
#Modifying override_ipv6_microsoft_code_page
$memberdhcp->override_ipv6_microsoft_code_page("true");
```

override_ipv6_options( )

The override_ipv6_options attribute controls whether the ipv6_options value in the DHCP member is used, instead of the Grid default.

The override_ipv6_options attribute can be specified explicitly. It is also set implicitly when ipv6_options is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_options. Set the parameter to "false" to inherit the grid-level setting for ipv6_options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_options
my $override_ipv6_options=$memberdhcp->override_ipv6_options( );
#Modifying override_ipv6_options
$memberdhcp->override_ipv6_options("true");
```

override_ipv6_recycle_leases( )

The override_ipv6_recycle_leases attribute controls whether the ipv6_recycle_leases value in the DHCP member is used, instead of the Grid default.

The override_ipv6_recycle_leases attribute can be specified explicitly. It is also set implicitly when ipv6_recycle_leases is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_recycle_leases. Set the parameter to "false" to inherit the grid-level setting for ipv6_recycle_leases.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_recycle_leases
my $override_ipv6_recycle_leases=$memberdhcp->override_ipv6_recycle_leases( );
#Modifying override_ipv6_recycle_leases
$memberdhcp->override_ipv6_recycle_leases("true");
```

override_ipv6_update_dns_on_lease_renewal( )

The override_ipv6_update_dns_on_lease_renewal attribute controls whether the ipv6_update_dns_on_lease_renewal value in the DHCP member is used, instead of the Grid default.

The override_ipv6_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when ipv6_update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ipv6_update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for ipv6_update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    #Getting override_ipv6_update_dns_on_lease_renewal
    my $override_ipv6_update_dns_on_lease_renewal=$memberdhcp-
>override_ipv6_update_dns_on_lease_renewal( );
    #Modifying override_ipv6_update_dns_on_lease_renewal
    $memberdhcp->override_ipv6_update_dns_on_lease_renewal("true");
```

override_lease_per_client_settings( )

Use this method to set or retrieve the override_lease_per_client_settings flag.

The override_lease_per_client_settings attribute can be specified explicitly. It is also set implicitly when lease_per_client_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for lease_per_client_settings. Set the parameter to "false" to inherit the grid-level setting for lease_per_client_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_lease_per_client_settings value
my $value = $object->override_lease_per_client_settings();

#Modify override_lease_per_client_settings value
$object->override_lease_per_client_settings("true");
```

override_lease_scavenge_time( )

The override_lease_scavenge_time attribute controls whether the lease_scavenge_time value in the member DHCP server is used, instead of the Grid default.

The override_lease_scavenge_time attribute can be specified explicitly. It is also set implicitly when lease_scavenge_time is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for lease_scavenge_time. Set the parameter to "false" to inherit the grid-level setting for lease_scavenge_time.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    #Getting override_lease_scavenge_time
    my $override_lease_scavenge_time=$memberdhcp->override_lease_scavenge_time( );
    #Modifying override_lease_scavenge_time
    $memberdhcp->override_lease_scavenge_time("true");
```

override_log_lease_events( )

The override_log_lease_events attribute controls whether the log_lease_events value in the member DHCP server is used, instead of the Grid default.

The override_log_lease_events attribute can be specified explicitly. It is also set implicitly when log_lease_events is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for log_lease_events. Set the parameter to "false" to inherit the grid-level setting for log_lease_events.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_log_lease_events
my $override_log_lease_events=$memberdhcp->override_log_lease_events( );
#Modifying override_log_lease_events
$memberdhcp->override_log_lease_events("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP member is used, instead of the Grid default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for preferred_lifetime. Set the parameter to "false" to inherit the grid-level setting for preferred_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_preferred_lifetime
my $override_preferred_lifetime=$memberdhcp->override_preferred_lifetime( );
#Modifying override_preferred_lifetime
$memberdhcp->override_preferred_lifetime("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the member DHCP server is used, instead of the Grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_update_dns_on_lease_renewal
my $override_update_dns_on_lease_renewal=$memberdhcp->override_update_dns_on_lease_renewal( );
#Modifying override_update_dns_on_lease_renewal
$memberdhcp->override_update_dns_on_lease_renewal("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the Grid Member DHCP is used, instead of the upper-level default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_valid_lifetime
my $override_valid_lifetime=$memberdhcp->override_valid_lifetime( );
#Modifying override_valid_lifetime
$memberdhcp->override_valid_lifetime("true");
```

ping_count( )

Use this method to set or retrieve the ping_count value of a member DHCP server. This value specifies the number of pings that the Infoblox appliance sends to an IP address to verify that it is not in use.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number of pings. Range is from 0 to 10, where 0 disables pings. The default value is 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ping_count
my $ping_count = $memberdhcp->ping_count();
#Modify ping_count
$memberdhcp->ping_count(4);
```

ping_timeout( )

Use this method to set or retrieve the ping_timeout value of a member DHCP server. This value indicates the number of seconds the appliance waits for a response to its ping.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Ping timeout value in seconds. Valid values are 0.1, 0.5, 1, 2, 3, 4 and 5 seconds. The default value is 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ping_timeout
my $ping_timeout = $memberdhcp->ping_timeout();
```

```
#Modify ping_timeout
$memberdhcp->ping_timeout(3);
```

preferred_lifetime( )

Use this method to set or retrieve preferred lifetime value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_dpreferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(12345); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(12345); will result in override_preferred_lifetime="true".

Parameter

Preferred lifetime value in seconds. The default value is 27000.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get preferred_lifetime
my $preferred_lifetime = $memberdhcp->preferred_lifetime();
#Modify preferred_lifetime
$memberdhcp->preferred_lifetime(12345);
```

pxe_lease_time( )

Use this method to set or retrieve the pxe_lease_time value of a member DHCP server. You can specify the duration of time it takes a host to connect to a boot server, such as a TFTP server, and download the file it needs to boot.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) that specifies the lease time in seconds. Default value is 43200 seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get pxe_lease_time
my $pxe_lease_time = $memberdhcp->pxe_lease_time();
#Modify pxe_lease_time
$memberdhcp->pxe_lease_time(200);
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases value of a member DHCP server. If you enable this check box, and then delete a DHCP range, the appliance stores active leases from this range up to one week after the leases expires.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set recycle_leases flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $memberdhcp->recycle_leases();
```

```
#Modify recycle_leases
$memberdhcp->recycle_leases("true");
```

retry_ddns_updates( )

Use this method to set or retrieve the retry_ddns_updates value of a member DHCP server. This value indicates whether the DHCP server makes repeated attempts to send DDNS updates to a DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the DHCP server to retry DDNS updates or "false" to disable this feature.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get retry_ddns_updates
my $retry_ddns_updates = $memberdhcp->retry_ddns_updates();
#Modify retry_ddns_updates
$memberdhcp->retry_ddns_updates("true");
```

syslog_facility( )

Use this method to set or retrieve the syslog_facility value of a member DHCP server. The syslog facility is the location on the syslog server to which you want to sort the syslog messages.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are: `"daemon", "local0", "local1", "local2", "local3", "local4", "local5", "local6", "local7"`.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get syslog_facility
my $syslog_facility = $memberdhcp->syslog_facility();
#Modify syslog_facility
$memberdhcp->syslog_facility("daemon");
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$memberdhcp->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$memberdhcp->update_dns_on_lease_renewal("true");
```

valid_lifetime( )

Use this method to set or retrieve the value of valid_lifetime for Grid Member DHCP.

Setting this method to a defined value implicitly sets the override_valid_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_valid_lifetime attribute to "false".

Note that when valid_lifetime is set to a defined value and override_valid_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->valid_lifetime(20000); $object->override_valid_lifetime("false"); will set override_valid_lifetime to "false", and the sequence $object->override_valid_lifetime("false"); $object->valid_lifetime(20000); will result in override_valid_lifetime="true".

Parameter

Valid lifetime value in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid_lifetime
my $valid_lifetime = $memberdhcp->valid_lifetime();
#Modify valid_lifetime
$memberdhcp->valid_lifetime(12345);
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to a member DHCP object, such as get and modify an object. This sample code also includes error handling for the operations.

#Preparation prior to operations on a member DHCP object

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",

NAME

Infoblox::Grid::Member::Discovery::ScanInterface - The scan interfaces structure.

DESCRIPTION

The object provides information about the scan interfaces.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Member::Discovery::ScanInterface->new(
    'scan_interface_type' => (LAN1|LAN2|MGMT), # Required
    'network_view' => $string,         # Required
    'vlan_id' => $uint,                # Optional
);
```

MODULE METHODS

The following functions can be applied to a Discovery Properties object.

Infoblox::Grid::Member::DiscoveryProperties->scan_interfaces( )

Use this method to set or retrieve the scan interfaces configured for the Grid member discovery properties. See Infoblox::Grid::Member::DiscoveryProperties->scan_interfaces() for parameters and return values.

Example

```
#Get scan_interfaces value
my $scan_interfaces = $discovery_properties->scan_interfaces();
#Modify scan_interfaces
$discovery_properties->scan_interfaces($scan_interfaces);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

scan_interface_type( )

Use this method to set or retrieve the probing interface type associated with the discovery probe member.

Parameter

The name of the probing interface (LAN1, LAN2, MGMT).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

The method returns the value of scan_interface_type attribute.

Example

```
# Get attribute value
my $value = $object->scan_interface_type();
# Modify attribute value
my $result = $object->scan_interface_type('LAN1');
```

network_view( )

Use this method to set or retrieve the name of the network view associated with the interface.

Parameter

The name of the network view associated with the interface.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

The method returns the name of the network view associated with the interface.

Example

```
# Get attribute value
my $value = $object->network_view();
# Modify attribute value
my $result = $object->('papi_network_view');
```

vlan_id( )

Use this method to set or retrieve information for the VLAN tag of the probing network. This method is allowed only for the LAN1 and LAN2 interfaces.

Parameter

VLAN tag of the probing network.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->vlan_id();
# Modify attribute value
$object->vlan_id(22);
```

NAME

Infoblox::Grid::Member::Discovery::SDNConfig - The SDN controller configuration structure.

DESCRIPTION

The object provides information about the SDN controller configuration.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Member::Discovery::SDNConfig->new(
    'sdn_type'                    => 'CISCO_APIC' | 'MERAKI', # Required
    'addresses'                   => ARRAY[$ipaddr | $fqdn],  # Required
    'network_view'                => $string,                 # Optional
    'protocol'                    => 'HTTP' | 'HTTPS',        # Optional
    'handle'                      => $string,                 # Required
    'password'                    => $string,                 # Optional
    'username'                    => $string,                 # Optional
    'api_key'                     => $string,                 # Optional
    'on_prem'                     => $bool,                   # Optional
    'use_global_proxy'            => $bool,                   # Optional
    'ca_certificate'              => $ca_cert,                # Optional
    'comment'                     => $string,                 # Optional
    'uuid'                        => $string,                 # Optional
    'network_interface_type'      => 'LAN1', 'LAN2', 'MGMT'   # Optional
    'network_interface_virtual_ip' => $vip                    # Optional
);
```

MODULE METHODS

The following functions can be applied to a SDN controller configuration structure.

Infoblox::Grid::Member::DiscoveryProperties->sdn_configs( )

Use this method to set or retrieve the SDN controller configurations configured for the Grid member discovery properties. See Infoblox::Grid::Member::DiscoveryProperties->sdn_configs() for parameters and return values.

Example

```
#Get sdn_configs value
my $sdn_configs = $discovery_properties->sdn_configs();
```

```
#Modify sdn_configs
$discovery_properties->sdn_configs([$sdn_config1, $sdn_config2]);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

sdn_type( )

Use this method to set or retrieve SDN controller type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'CISCO_APIC' and 'MERAKI'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->sdn_type();
# Modify attribute value
my $result = $object->sdn_type('CISCO_APIC');
```

addresses( )

Use this method to set or retrieve SDN controller address or FQDN.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The desired SDN address or Fully-Qualified Domain Name (FQDN) in a string format as array.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->addresses();
# Modify attribute value
my $result = $object->addresses(['10.11.0.1']);
```

network_view( )

Use this method to set or retrieve the network view associated with SDN controller.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a network view name that is associated with a SDN controller in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->network_view();
```

```
# Modify attribute value
my $result = $object->network_view('papi_network_view');
```

protocol( )

Use this method to set or retrieve the connection protocol for the SDN controller.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'HTTP' and 'HTTPS'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->protocol();
# Modify attribute value
$object->protocol('HTTP');
```

handle( )

Use this method to set or retrieve SDN controller unique configuration handle.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired SDN controller unique configuration handle in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->handle();
# Modify attribute value
$object->handle('handle');
```

password( )

Use this method to set SDN controller login password. This is a write-only attribute.

Include the specified parameter to set the attribute value.

Parameter

SDN controller login password.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
# Modify attribute value
$object->password('password');
```

username( )

Use this method to set or retrieve SDN controller login name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired SDN controller login name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->username();
# Modify attribute value
$object->username('username');
```

api_key( )

Use this method to set or retrieve SDN controller api key.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired SDN controller api key in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->api_key();
# Modify attribute value
$object->api_key('api_key');
```

on_prem( )

Use this method to set or retrieve SDN controller on-prem value. True if controller is on-premises. Otherwise we consider it is in cloud.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired SDN controller on-prem in a boolean format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->on_prem();
# Modify attribute value
$object->on_prem(true);
```

use_global_proxy( )

Use this method to set or retrieve SDN controller use_global_proxy value. Use global proxy settings to access SDN controller.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired SDN controller use_global_proxy value in a boolean format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->use_global_proxy();
# Modify attribute value
```

```
$object->use_global_proxy(false);
```

ca_certificate( )

Use this method to set or retrieve the CA certificate.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::CACertificate object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->ca_certificate();
# Modify attribute value
my $result = $object->ca_certificate($ca_cert);
```

comment( )

Use this method to set or retrieve the descriptive comment for the SDN controller configuration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->comment();
# Modify attribute value
$object->comment('SDN configuration');
```

uuid( )

Use this method to set or retrieve SDN controller configuration UUID.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired SDN controller uuid in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->uuid();
# Modify attribute value
$object->uuid('ABCDEF');
```

network_interface_type( )

Use this method to set or retrieve SDN controller network interface type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'LAN1', 'LAN2', 'MGMT'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->network_interface_type();
# Modify attribute value
$object->network_interface_type('LAN1');
```

network_interface_virtual_ip( )

Use this method to set or retrieve SDN controller network interface virtual ip.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired SDN controller interface virtual ip in a string format in case network interface type is VLAN.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->network_interface_virtual_ip();
# Modify attribute value
$object->network_interface_virtual_ip(.);
```

NAME

Infoblox::Grid::Member::Discovery::VRF - Object represents the relation between network view and the virtual network membership.

DESCRIPTION

This object is used to represents relation between network view and the virtual network membership. Object is read-only.

SESSION METHODS

Infoblox::Session->get()

Use this method to retrieve all the matching virtual network objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

Apply the following attributes to get a specific virtual network objects:

```
name                - Optional. A name in string format.
description         - Optional. A description in string format.
route_distinguisher - Optional. Route distinguisher associated with the VRF in sting format.
network_view        - Optional. Name of the network view associated with the VRF in sting format.
```

Returns

Returns Virtual network membership object.

Example

```
#Get VRF object with the name 'VRF1'
my $vrf_obj = $session->get(
    object  => "Infoblox::Grid::Member::Discovery::VRF" ,
    name    => 'VRF1'
);
```

Infoblox::Session->search()

Use this method to search for a virtual network objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a virtual network object:

name                - Optional. A name in string format (regular expression).
description         - Optional. A description in string format (regular expression).
route_distinguisher - Optional. Route distinguisher associated with the VRF in sting format.
network_view        - Optional. Name of the network view associated with the VRF in sting format.
```

Returns

Returns Virtual network membership object(s).

Example

```
# Get all VRFs
my @all_vrfs = $session->search(
      object => 'Infoblox::Grid::Member::Discovery::VRF',
      name => '^.*$'
);

# Get vrf by Route distinguisher
my $vrf = $session->search(
      object => 'Infoblox::Grid::Member::Discovery::VRF',
      route_distinguisher => '123:500'
);
```

METHODS

This section describes all the methods that can be used to retrieve values from VRF object.

`name()`

Use this method to retrieve name associated with the VRF. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get VRF name
my $vrf_name = $vrf->name();
```

`network_view()`

Use this method to retrieve name of network view associated with the VRF. This is a read-only attribute.

Parameter

None

Returns

The returned string contains name network view. This is a read-only attribute.

Example

```
#Get VRF network view name
my $vrf_nv = $vrf->network_view();
```

`route_distinguisher()`

Use this method to retrieve route distinguisher associated with the VRF. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get VRF route distinguisher
my $vrf_rd = $vrf->route_distinguisher();
```

`description()`

Use this method to retrieve description associated with the VRF. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get VRF description
my $vrf_desc = $vrf->description();
```

device()

Use this method to retrieve Infoblox::Grid::Discovery::Device object from which this VRF membership configuration was collected. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Device partial object.

Example

```
#Get VRF device
my $vrf_device = $vrf->device();
```

NAME

Infoblox::Grid::Member::DiscoveryProperties - Grid member discovery properties.

DESCRIPTION

The object provides information about Grid member discovery properties.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Member::DiscoveryProperties->new(
    'member'                    => $string,                     # Optional
    'enable_service'            => 'true' | 'false',            # Optional
    'scan_interfaces'           => [$si1, ...],                 # Optional
    'role'                      => 'DNM' | 'DNP' | 'NONE',      # Optional
    'seed_routers'              => [$seed1, ...],               # Optional
    'snmp3_credentials'         => [$snmp3, ...],               # Optional
    'override_snmp3_credentials' => 'true' | 'false',           # Optional
    'snmp_credentials'          => [$snmp, ...],                # Optional
    'override_snmp_credentials'  => 'true' | 'false',           # Optional
    'cli_credentials'           => [$cli1, ...],                # Optional
    'override_cli_credentials'   => 'true' | 'false',           # Optional
    'sdn_configs'               => [$conf1, ...],               # Optional
);
```

SESSION METHODS

This section describes all the methods in Infoblox::Session that you can apply to the object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific object:

 member - Optional. The member name.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::Member::DiscoveryProperties',
    'member' => 'member.com',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify role.
$object->role("DNP");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a object:

 member - Optional. The member name.
```

Example

```
# search for all objects
my @retrieved_objs = $session->search(
    'object' => 'Infoblox::Grid::Member::DiscoveryProperties',
    'member' => 'member.com',
);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

sdn_configs( )

Use this method to set or retrieve the list of SDN configurations for a given probe Member.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Member::Discovery::SDNConfig objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->sdn_configs();
# Construct SDN config
my $conf = Infoblox::Grid::Member::Discovery::SDNConfig->new(
    'sdn_type'       => 'CISCO_APIC',
    'addresses'      => ['apic.aci.com'],
    'network_view'   => 'default',
    'protocol'       => 'HTTPS',
    'handle'         => 'ACIConf1',
    'password'       => 'infoblox',
    'username'       => 'admin',
    'ca_certificate' => $cert,
    'comment'        => 'test_sdn_config',
);
$object->sdn_configs([$conf]);
```

default_seed_routers( )

Use this method to retrieve a list of default seed routers. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->default_seed_routers();
```

enable_service( )

Use this method to enable or disable the discovery service.

Parameter

Specify "true" to enable the discovery service or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->enable_service();
# Modify attribute value
$object->enable_service('true');
```

cli_credentials( )

Use this method to set or retrieve the Discovery CLI credentials.

Setting this method to a defined value implicitly sets the override_cli_credentials method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_cli_credentials attribute to "false".

Note that when cli_credentials is set to a defined value and override_cli_credentials is set to "false", the last operation takes precedence. Thus the sequence $object->cli_credentials([$snmp]); $object->override_cli_credentials("false"); will set override_cli_credentials to "false", and the sequence $object->override_cli_credentials("false"); $object->cli_credentials([$snmp]); will result in override_cli_credentials="true".

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::CLICredential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->cli_credentials();
# Modify attribute value
$object->cli_credentials([$cli1, $cli2]);
```

member( )

Use this method to set or retrieve the member name.

Parameter

The member name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->member();
```

```
# Modify attribute value
$object->member('infoblox.com');
```

override_snmp3_credentials( )

The override_snmp3_credentials attribute controls whether the snmp3_credentials value in the member is used, instead of the grid default.

The override_snmp3_credentials attribute can be specified explicitly. It is also set implicitly when snmp3_credentials is set to a defined value.

Parameter

Specify "true" to set the override_snmp3_credentials flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->override_snmp3_credentials();
# Modify attribute value
$object->override_snmp3_credentials('true');
```

override_cli_credentials( )

The override_cli_credentials attribute controls whether the cli_credentials value in the member is used, instead of the grid default.

The override_cli_credentials attribute can be specified explicitly. It is also set implicitly when cli_credentials is set to a defined value.

Parameter

Specify "true" to set the override_cli_credentials flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->override_cli_credentials();
# Modify attribute value
$object->override_cli_credentials('true');
```

override_snmp_credentials( )

The override_snmp_credentials attribute controls whether the snmp_credentials value in the member is used, instead of the grid default.

The override_snmp_credentials attribute can be specified explicitly. It is also set implicitly when snmp_credentials is set to a defined value.

Parameter

Specify "true" to set the override_snmp_credentials flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->override_snmp_credentials();
# Modify attribute value
$object->override_snmp_credentials('true');
```

role( )

Use this method to set or retrieve the role of the discovery member.

Parameter

Valid value is 'DNM', 'DNP' or 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->role();
# Modify attribute value
$object->role('NONE');
```

seed_routers( )

Use this method to set or retrieve seed routers.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::SeedRouter objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->seed_routers();
# Modify attribute value
$object->seed_routers([$seed1, $seed2]);
```

snmp3_credentials( )

Use this method to set or retrieve discovery SNMPv3 credentials.

Setting this method to a defined value implicitly sets the override_snmp3_credentials method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_snmp3_credentials attribute to "false".

Note that when snmp3_credentials is set to a defined value and override_snmp3_credentials is set to "false", the last operation takes precedence. Thus the sequence $object->snmp3_credentials([$snmp3]); $object->override_snmp3_credentials("false"); will set override_snmp3_credentials to "false", and the sequence $object->override_snmp3_credentials("false"); $object->snmp3_credentials([$snmp3]); will result in override_snmp3_credentials="true".

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::SNMP3Credential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->snmp3_credentials();
# Modify attribute value
$object->snmp3_credentials([$snmp3]);
```

snmp_credentials( )

Use this method to set or retrieve SNMPv1 and SNMPv2 credentials.

Setting this method to a defined value implicitly sets the override_snmp_credentials method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_snmp_credentials attribute to "false".

Note that when snmp_credentials is set to a defined value and override_snmp_credentials is set to "false", the last operation takes precedence. Thus the sequence $object->snmp_credentials([$snmp]); $object->override_snmp_credentials("false"); will set override_snmp_credentials to "false", and the sequence $object->override_snmp_credentials("false"); $object->snmp_credentials([$snmp]); will result in override_snmp_credentials="true".

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::SNMPCredential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->snmp_credentials();
# Modify attribute value
$object->snmp_credentials([$snmp]);
```

test_credential( )

Use this method to test credentials.

Parameter

```
id               - Optional. The test credential ID.
```

The following members are supported when id is defined:

```
start            - Optional. The start position of the text.
```

The following members are supported when id is not defined:

```
view             - Optional. The network view name. The default value is the system-defined default
network view.

type             - Optional if one of the following is defined: cli_credentials, snmp_credential or
snmp3_credential. Otherwise, this member is required. The valid value is 'CLI', 'SNMP' or 'SNMP3'.

device           - Required if address is not defined. The Infoblox::Grid::Discovery::Device object.

member           - Optional. The discovery member name.

address          - Required if device is not defined. The IP address of the device.

cli_credentials  - Optional. At least one of the following must be defined: cli_credentials,
snmp_credential, or  snmp3_credential. The array reference that contains
Infoblox::Grid::Discovery::CLICredential objects.

snmp_credential  - Optional. At least one of the following must be defined: cli_credentials,
snmp_credential, or  snmp3_credential. The Infoblox::Grid::Discovery::SNMPCredential object.

snmp3_credential - Optional. At least one of the following must be defined: cli_credentials,
snmp_credential, or snmp3_credential. The Infoblox::Grid::Discovery::SNMP3Credential object.
```

Returns

The method returns an Infoblox::Grid::Discovery::TestCredential object when the operation succeeds, and returns false when the operation fails.

Example

```
# Get a test credential ID
my $result = $object->test_credential(
   'address'         => '10.0.0.1',
   'snmp_credential' => $snmp,
);

# Get detailed information by id
if (ref($result) eq 'Infoblox::Grid::Discovery::TestCredential') {
    $result = $object->test_credential('id' => $result->id());
}
```

scan_interfaces( )

Use this method to set or retrieve the scan interface configuration for a given probe member.

Parameter

Valid value is an array reference that contains Infoblox::Grid::Member::Discovery::ScanInterface objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->scan_interfaces();
# Modify attribute value
$object->scan_interfaces([$interface1, $interface2]);
```

NAME

Infoblox::Grid::Member::DNS - Grid Member DNS object.

DESCRIPTION

You can configure the DNS properties of a grid member, including enabling/disabling DNS services and other DNS service parameters. The service configurations of a grid are inherited by all members. For this reason, it is recommended that you configure services at the grid level before configuring member services. When you configure DNS services at the grid level, all grid members inherit the grid-level configuration settings, unless you specifically override them for selected members.

CONSTRUCTOR

The Infoblox::Grid::Member::DNS object is automatically generated upon the successful installation of the Infoblox appliance. It does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a grid member DNS object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

Apply the following attributes to get a specific grid member DNS object:

```
name - Optional.   Host name in string format
ipv4addr - Optional.   IPv4 address of the member
ipv6addr - Optional.   IPv6 address of the member
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
my $object   = $session->get(
   object    => "Infoblox::Grid::Member::DNS",
   name      => "infoblox.localdomain",
    );

# get all Grid::Member::DNS objects with a given extensible attribute
```

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member::DNS",
    extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to take effect. See Infoblox::Session->restart() method.

Example

```
#Use this method to modify the enable_dns  property.
$object->enable_dns("false");
#Submit modification
my $response = $session->modify( $object );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the DNS properties of a grid member.

anonymize_response_logging( )

Use this method to set or retrieve the flag that indicates whether the anonymization of captured DNS responses is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable anonymization of captured DNS responses or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get anonymize_response_logging value
my $anonymize_response_logging = $object->anonymize_response_logging();

#Modify anonymize_response_logging value
$object->anonymize_response_logging('true');
```

allow_gss_tsig_zone_updates( )

Use this method to enable/disable GSS-TSIG zone updates for this member. This setting overrides the grid GSS-TSIG zone update settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to allow GSS-TSIG zone updates for this member or "false" to disallow them. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get allow_gss_tsig_zone_updates
my $allow_gss_tsig_zone_updates = $memberdns->allow_gss_tsig_zone_updates( );
#Modify allow_gss_tsig_zone_updates
$memberdns->allow_gss_tsig_zone_updates("true");
```

allow_query( )

Use this method to add or retrieve an allow_query list.

Select "allow query" to permit queries from the specified IPv4 or IPv6 addresses and networks. The list specifies IP `address(es)` and/or `network(s)` from which queries are allowed or denied. The appliance can also use Transaction Signature (TSIG) keys to authenticate the

queries. This setting overrides the grid query settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses, networks and/or Infoblox::DNS::TSIGKey object(s). To deny queries, add "!" as a prefix to `address(es)` and network(s). Specify "any" to allow queries from any address. By default, queries are allowed from any address. Undefine the value to use the Grid::DNS level allow_query list.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get allow_query
$memberdns->allow_query();
#Modify allow_query
$memberdns->allow_query( ["any"] );

#Specifying TSIG keys
my $tsig_key1 = $session->gen_tsig_key();
my $query_key = Infoblox::DNS::TSIGKey->new(
  name => "query_key1",
  key  => $tsig_key1
);
#Modify allow_query
$memberdns->allow_query( [ "10.0.0.10" , "20.0.0.0/24"
,"2001::123a","2003::222/64","!"."30.0.0.30" , "!"."40.10.0.0/24","!"."2004::125b","!"."2006::34bc"]
);

#Modify allow_query to use Grid level settings
$memberdns->allow_query(undef);
#Use Infoblox::Grid::NamedACL
$memberdns->allow_query($nacl);
```

allow_recursive_query( )

Use this method to enable/disable responses to recursive queries. This setting overrides grid recursive query settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to allow responses to recursive queries or "false" to reject recursive queries. The default value is "false". Undefine to use the Grid::DNS level allow_recursive_query setting. Note: You should also undefine the recursive_query_list list to use the Grid::DNS level settings.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get allow_recursive_query
my $allow_recursive_query = $memberdns->allow_recursive_query( );
#Modify allow_recursive_query
$memberdns->allow_recursive_query("true");
```

allow_transfer( )

Use this method to allow or reject zone transfers from specified IPv4 or IPv6 addresses and networks or to allow transfers from hosts authenticated by Transaction signature (TSIG) key. This setting overrides the grid zone transfer settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses, networks and/or Infoblox::DNS::TSIGKey object(s). To reject zone transfers, add '!' as a prefix to IP addresses and networks. Specify "any" to allow any transfer, or undefine to use the Grid::DNS level allow_transfer list.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting allow_transfer
my $memberdns = $object->allow_transfer( );
#Modifying allow_transfer
$memberdns->allow_transfer(["any"]);

#Specifying TSIG keys
my $tsig_key1 = $session->gen_tsig_key();
my $key1 = Infoblox::DNS::TSIGKey->new(
  name => "key1",
  key  => $tsig_key1
);
my $key2 = Infoblox::DNS::TSIGKey->new(
  name => "tsig_xfer",
  key  => ":2xCOMPAT"
);
#Modifying allow_transfer
$memberdns->allow_transfer(["10.0.0.10", $key1, "20.0.0.0/24", $key2,
"2004::325f","2007::876c/64","!"."30.0.0.30", "!"."40.10.0.0/24"]);

#Use Grid::DNS level allow_transfer list
$memberdns->allow_transfer(undef);

#Use Infoblox::Grid::NamedACL
$memberdns->allow_transfer($nacl);
```

allow_update( )

Use this method to allow or reject dynamic updates from specified IPv4 or IPv6 addresses, networks or from host authenticated by TSIG key. This setting overrides grid update settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses, networks and/or Infoblox::DNS::TSIGKey object(s). To reject updates, add '!' as a prefix to IP addresses and networks. Specify "any" to allow any update, or undefine to use the Grid::DNS level allow_update list.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting allow_update
$memberdns->allow_update();
#Modifying allow_update
$memberdns->allow_update(["any"]);

#Creating TSIG Key object.
my $update_key1 = $session->gen_tsig_key();
my $up_key1 = Infoblox::DNS::TSIGKey->new(
  name => "update_key",
  key  => $update_key1
  );
#Modifying allow_update
$memberdns->allow_update([ $up_key1, "10.0.0.10", "20.0.0.0/24","2008::129b","!"."30.0.0.30",
"!"."40.10.0.0/24","!"."2004::76bc/64"]);

#Use Grid::DNS level allow_update list
$memberdns->allow_update(undef);
$memberdns->update_keys(undef);
#Use Infoblox::Grid::NamedACL
$memberdns->allow_update($nacl);
```

attack_mitigation( )

Use this method to set or retrieve DNS attack mitigation settings for the member.

Setting this method to a defined value implicitly sets the override_attack_mitigation method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_attack_mitigation method to "false".

Note that when attack_mitigation is set to a defined value and override_attack_mitigation is set to "false", the last operation takes

precedence. Thus the sequence $object->attack_mitigation($attack_mitigation); $object->override_attack_mitigation("false"); will set override_attack_mitigation to "false", and the sequence $object->override_attack_mitigation("false"); $object->attack_mitigation($attack_mitigation); will result in override_attack_mitigation="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::AttackMitigation object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attack_mitigation value
my $attack_mitigation = $memberdns->attack_mitigation();
#Modify attack_mitigation
$memberdns->attack_mitigation($attack_mitigation);
```

auto_blackhole( )

Use this method to set or retrieve the auto blackhole settings for the member.

Setting this method to a defined value implicitly sets the override_auto_blackhole method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_auto_blackhole method to "false".

Note that when auto_blackhole is set to a defined value and override_auto_blackhole is set to "false", the last operation takes precedence. Thus the sequence $object->auto_blackhole($auto_blackhole); $object->override_auto_blackhole("false"); will set override_auto_blackhole to "false", and the sequence $object->override_auto_blackhole("false"); $object->auto_blackhole($auto_blackhole); will result in override_auto_blackhole="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::AutoBlackHole object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get auto_blackhole value
my $auto_blackhole = $memberdns->auto_blackhole();
#Modify auto_blackhole
$memberdns->auto_blackhole($auto_blackhole);
```

auto_create_a_and_ptr_for_lan2( )

Use this method to enable/disable the auto-generation of A and PTR records for the LAN2 IP address, if DNS service is enabled on LAN2.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the auto-generation of A and PTR records for the LAN2 IP address or "false" to disable it. Default is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting auto_create_a_and_ptr_for_lan2
my $auto_create_a_and_ptr_for_lan2 = $memberdns->auto_create_a_and_ptr_for_lan2( );
#Modifying auto_create_a_and_ptr_for_lan2
$memberdns->auto_create_a_and_ptr_for_lan2("true");
```

auto_create_a_and_ipv6ptr_for_lan2( )

Use this method to enable/disable the auto-generation of AAAA and IPv6 PTR records for the LAN2 IP address, if DNS service is enabled on LAN2.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the auto-generation of AAAA and IPv6 PTR records for the LAN2 IP address or "false" to disable it. Default is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting auto_create_a_and_ipv6ptr_for_lan2
my $auto_create_a_and_ipv6ptr_for_lan2 = $memberdns->auto_create_a_and_ipv6ptr_for_lan2( );
#Modifying auto_create_a_and_ipv6ptr_for_lan2
$memberdns->auto_create_a_and_ipv6ptr_for_lan2("true");
```

auto_sort_views( )

Use this method to enable/disable a grid member to automatically sort DNS views. The order of the DNS views determines the order in which the appliance checks the match lists.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the automatic sorting of DNS views or "false" to disable it. Default is "false"

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting auto_sort_views
$memberdns->auto_sort_views( );
#Modifying auto_sort_views
$memberdns->auto_sort_views("true");
```

blackhole_list( )

Use this method to set or retrieve the list of IPv4 or IPv6 addresses and networks from which DNS queries are blocked. This setting overrides the grid blackhole_list.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses and networks. To allow queries, add '!' as the prefix to IP addresses and networks. Specify "any" to block queries or undefine the usage of Grid::DNS level blackhole_list. Note: You should also undefine the enable_blackhole list to use Grid::DNS level settings.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
    #Getting blackhole_list
    my $blackhole_list = $memberdns->blackhole_list( );
    #Modifying blackhole_list
    $memberdns->blackhole_list(["any"]);
    #Modifying blackhole_list
    $memberdns->blackhole_list(["10.0.0.10",
"20.0.0.0/24","2010::256/64","!"."2011::23cb/64","!"."30.0.0.30", "!"."40.10.0.0/24"]);
    #Use Grid::DNS level blackhole_list
    $memberdns->blackhole_list(undef);
    $memberdns->enable_blackhole(undef);
```

```
#Use Infoblox::Grid::NamedACL
$memberdns->blackhole_list($nacl);
```

blacklist_action( )

Use this method to specify the action to perform when a domain name matches the pattern defined in a rule that is specified by the blacklist_ruleset method.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "REDIRECT" or "REFUSE". The default value is "REFUSE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Examples

```
#Get blacklist_action
my $blacklist_action = $memberdns->blacklist_action();
#Modify blacklist_action
$memberdns->blacklist_action("REDIRECT");
```

blacklist_log_query( )

Use this method to set or retrieve the flag that indicates whether blacklist redirection queries are logged.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable logging, or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_log_query
my $blacklist_log_query = $memberdns->nxdomain_log_query( );
#Modify blacklist_log_query
$memberdns->blacklist_log_query("true");
```

blacklist_redirect_addresses( )

Use this method to specify the IP addresses the appliance includes in the response it sends in place of a blacklisted IP address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of IPv4 addresses. The default value is undefined.

Setting this parameter to ["10.0.0.10", "10.0.0.20"] or [], implicitly sets the override_blacklist_redirect attribute to "true". Setting this parameter to undefined causes the appliance to use the grid-level blacklist redirection settings and automatically sets the override_blacklist_redirect attribute to "false" if "enable_blacklist_redirect" is also undefined. But if "enable_blacklist_redirect" contains a value, then the override_blacklist_redirect attribute is set to "true".

Note that when blacklist_redirect_addresses contains a valid array reference and override_blacklist_redirect is set to "false", the last operation takes precedence. Thus the sequence $memberdns->blacklist_redirect_addresses(["10.0.0.10", "10.0.0.20"]); $memberdns->override_blacklist_redirect("false"); sets override_blacklist_redirect to "false", and the sequence $memberdns->override_blacklist_redirect("false"); $memberdns->blacklist_redirect_addresses(["10.0.0.10", "10.0.0.20"]); sets override_blacklist_redirect to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_redirect_addresses
```

```
my $blacklist_redirect_addresses = $memberdns->blacklist_redirect_addresses( );
#Modify blacklist_redirect_addresses
$memberdns->blacklist_redirect_addresses(["10.0.0.10", "10.0.0.20"]);
```

blacklist_redirect_ttl( )

Use this method to set or retrieve the TTL value of the synthetic DNS responses that result from blacklist redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the TTL in seconds. The default value is 60.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_redirect_ttl
my $blacklist_redirect_ttl = $memberdns->blacklist_redirect_ttl( );
#Modify blacklist_redirect_ttl
$memberdns->blacklist_redirect_ttl(60);
```

blacklist_rulesets( )

Use this method to specify or retrieve Infoblox::DNS::Ruleset object names assigned at the grid level for blacklist redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains the names of the Infoblox::DNS::Ruleset objects assigned to the grid. The names must be in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_rulesets
my $blacklist_rulesets = $memberdns->blacklist_rulesets();
#Modify blacklist_rulesets
$memberdns->blacklist_rulesets(["ruleset1", "ruleset2"]);
```

bind_check_names_policy( )

Use this method to set or retrieve the BIND check names policy, which indicates the action the appliance takes when it encounters host names that do not comply with the Strict Hostname Checking policy. This method applies only if the host name restriction policy is set to "Strict Hostname Checking".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The allowed values of the parameter are "fail", "warn" or undefined. This indicates the desired BIND behavior in the case of illegal hostnames. The default value is undefined, which means the appliance ignores illegal hostnames.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bind_check_names_policy value
my $names_policy = $memberdns->bind_check_names_policy();
#Modify bind_check_names_policy
$memberdns->bind_check_names_policy("warn");
```

bind_hostname_directive( )

Use this method to set or retrieve the value of BIND 'hostname' directive.

Setting this method to a defined value implicitly sets the override_bind_hostname_directive method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_bind_hostname_directive method to "false".

Note that when bind_hostname_directive is set to a defined value and override_bind_hostname_directive is set to "false", the last operation takes precedence. Thus the sequence $object->bind_hostname_directive("HOSTNAME"); $object->override_bind_hostname_directive("false"); will set override_bind_hostname_directive to "false", and the sequence $object->override_bind_hostname_directive("false"); $object->bind_hostname_directive("true"); will result in override_bind_hostname_directive="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are "NONE", "HOSTNAME" and "USER_DEFINED". The default value is "NONE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bind_hostname_directive
my $bind_hostname_directive = $memberdns->bind_hostname_directive();
#Modify bind_hostname_directive
$memberdns->bind_hostname_directive("HOSTNAME");
```

bind_hostname_directive_fqdn( )

Use this method to set or retrieve the value of BIND user-defined hostname for 'hostname' directive.

Note that to enable user-defined 'hostname' the bind_hostname_directive should be set to "USER_DEFINED".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is Fully-Qualified Domain Name (FQDN) in a string format. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bind_hostname_directive_fqdn
my $bind_hostname_directive_fqdn = $memberdns->bind_hostname_directive_fqdn();
#Modify bind_hostname_directive_fqdn
$memberdns->bind_hostname_directive_fqdn("foo-bar.com");
```

capture_dns_queries_on_all_domains( )

Use this method to set or retrieve the flag that indicates whether the capturing of DNS queries for all domains is enabled or disabled.

Setting this method to a defined value implicitly sets the override_capture_dns_queries_on_all_domains method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_capture_dns_queries_on_all_domains method to "false".

Note that when capture_dns_queries_on_all_domains is set to a defined value and override_capture_dns_queries_on_all_domains is set to "false", the last operation takes precedence. Thus the sequence $object->capture_dns_queries_on_all_domains("true"); $object->override_capture_dns_queries_on_all_domains("false"); will set override_capture_dns_queries_on_all_domains to "false", and the sequence $object->override_capture_dns_queries_on_all_domains("false"); $object->capture_dns_queries_on_all_domains("true"); will result in override_capture_dns_queries_on_all_domains="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable capturing of DNS queries for all domains or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get capture_dns_queries_on_all_domains value
my $capture_dns_queries_on_all_domains = $object->capture_dns_queries_on_all_domains();

#Modify capture_dns_queries_on_all_domains value
$object->capture_dns_queries_on_all_domains('true');
```

copy_xfer_to_notify( )

Use this method to enable/disable copying of the allowed IPs from zone transfer list into also-notify statement in named.conf.

Parameter

Set the parameter to "true" to enable copying of the allowed IPs from zone transfer list into also-notify statement in named.conf. Set the parameter to "false" to disable it.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $memberdns->copy_xfer_to_notify();
# Modify attribute value
$memberdns->copy_xfer_to_notify('true');
```

custom_root_name_servers( )

Use this method to set or retrieve the list of customized root nameserver(s). You can either select and use Internet root name servers or specify custom root name servers by providing a host name and IP address to which the Infoblox appliance can send queries. Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::DNS::RootNameServer object(s).

Returns

If you specify a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the root nameserver list
my $rootNS_list = $memberdns->custom_root_name_servers();
#Modify the root nameserver list
#Creating RootNameServer objects.
my $rootns1 = Infoblox::DNS::RootNameServer->new(
    ipv4addr  => "4.4.4.4",
    host_name => "rns1.test.com",
    );

my $rootns2 = Infoblox::DNS::RootNameServer->new(
    ipv4addr  => "5.5.5.5",
    host_name => "rns2.test.com",
    );

$memberdns->custom_root_name_servers([$rootns1, $rootns2]);
```

disable_edns( )

Use this method to disable or enable EDNS0 support for queries that require recursive resolution on Grid members.

Setting this method to a defined value implicitly sets the override_disable_edns method to "true". Setting the parameter to undefined causes the appliance to use the grid DNS default and automatically resets the override_disable_edns method to "false".

Note that when disable_edns is set to a defined value and override_disable_edns is set to "false", the last operation takes precedence.

Thus the sequence $object->disable_edns("true"); $object->override_disable_edns("false"); will set override_disable_edns to "false", and the sequence $object->override_disable_edns("false"); $object->disable_edns("true"); will result in override_disable_edns="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to disable EDNS0 or "false" to enable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable_edns flag
my $disable_edns = $memberdns->disable_edns();
#Modify disable_edns flag
$memberdns->disable_edns("true");
```

dns_cache_acceleration_ttl( )

Use this method to set or retrieve the minimum TTL value, in seconds, that a DNS record must have in order for it to be cached by the DNS Cache Acceleration service.

Setting this method to a defined value implicitly sets the override_dns_cache_acceleration_ttl method to "true". Setting the parameter to undefined causes the appliance to use the grid DNS default and automatically resets the override_dns_cache_acceleration_ttl method to "false".

Note that when dns_cache_acceleration_ttl is set to a defined value and override_dns_cache_acceleration_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->dns_cache_acceleration_ttl(60); $object->override_dns_cache_acceleration_ttl("false"); will set override_dns_cache_acceleration_ttl to "false", and the sequence $object->override_dns_cache_acceleration_ttl("false"); $object->dns_cache_acceleration_ttl(30); will result in override_dns_cache_acceleration_ttl="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An integer from 1 to 65000 that represents the TTL in seconds. The default value is 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_cache_acceleration_ttl
my $dns_cache_acceleration_ttl = $member_dns->dns_cache_acceleration_ttl( );
#Modify dns_cache_acceleration_ttl
$member_dns->dns_cache_acceleration_ttl(60);
```

dns_cache_acceleration_status( )

Use this method to retrieve the DNS cache acceleration status.

Parameter

None.

Returns

The method returns the attribute value, which is one of the following: "Failed", "Inactive", "Offline", "Unknown", "Warning", or "Working".

Example

```
#Get dns_cache_acceleration_status
my $dns_cache_acceleration_status = $member_dns->dns_cache_acceleration_status( );
```

dns_health_check_anycast_control( )

Use this method to set or retrieve the flag that indicates whether the anycast failure (BFD session down) is enabled on Member failure or not.

Setting this parameter to defined value, implicitly sets the override_dns_health_check attribute to "true". Setting this parameter to undefined causes the appliance to use the Grid-level DNS health check settings and automatically sets the override_dns_health_check attribute to "false" if following fields are undefined:

```
dns_health_check_domain_list
dns_health_check_recursion_flag
dns_health_check_interval
dns_health_check_retries
dns_health_check_timeout
enable_dns_health_check
```

But if any of the fields above contains a value, then the override_dns_health_check attribute is set to "true".

Note that when dns_health_check_anycast_control contains a value and override_dns_health_check is set to "false", the last operation takes precedence. Thus the sequence $zone->dns_health_check_anycast_control("true"); $zone->override_dns_health_check("false"); sets override_dns_health_check to "false", and the sequence $zone->override_dns_health_check("false"); $zone->dns_health_check_anycast_control("true"); sets override_dns_health_check to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable anycast failure on Member failure, and 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_anycast_control value
my $value = $object->dns_health_check_anycast_control();

#Modify dns_health_check_anycast_control value
$object->dns_health_check_anycast_control('true');
```

dns_health_check_domain_list( )

Use this method to set or retrieve the list of domain names for the DNS health check.

Setting this parameter to defined value, implicitly sets the override_dns_health_check attribute to "true". Setting this parameter to undefined causes the appliance to use the Grid-level DNS health check settings and automatically sets the override_dns_health_check attribute to "false" if following fields are undefined:

```
dns_health_check_recursion_flag
dns_health_check_anycast_control
dns_health_check_interval
dns_health_check_retries
dns_health_check_timeout
enable_dns_health_check
```

But if any of the fields above contains a value, then the override_dns_health_check attribute is set to "true".

Note that when dns_health_check_anycast_control contains a value and override_dns_health_check is set to "false", the last operation takes precedence. Thus the sequence $zone->dns_health_check_domain_list(['domain1.com', 'domain2.com']); $zone->override_dns_health_check("false"); sets override_dns_health_check to "false", and the sequence $zone->override_dns_health_check("false"); $zone->dns_health_check_domain_list(['domain1.com', 'domain2.com']); sets override_dns_health_check to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains desired domain names in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_domain_list value
my $value = $object->dns_health_check_domain_list();

#Modify dns_health_check_domain_list value
$object->dns_health_check_domain_list(['foo.com', 'bar.net']);
```

dns_health_check_interval( )

Use this method to set or retrieve the time interval (in seconds) for DNS health check.

Setting this parameter to defined value, implicitly sets the override_dns_health_check attribute to "true". Setting this parameter to undefined causes the appliance to use the Grid-level DNS health check settings and automatically sets the override_dns_health_check attribute to "false" if following fields are undefined:

```
dns_health_check_domain_list
dns_health_check_recursion_flag
dns_health_check_anycast_control
dns_health_check_retries
dns_health_check_timeout
enable_dns_health_check
```

But if any of the fields above contains a value, then the override_dns_health_check attribute is set to "true".

Note that when dns_health_check_interval contains a value and override_dns_health_check is set to "false", the last operation takes precedence. Thus the sequence $zone->dns_health_check_interval("500"); $zone->override_dns_health_check("false"); sets override_dns_health_check to "false", and the sequence $zone->override_dns_health_check("false"); $zone->dns_health_check_interval("500"); sets override_dns_health_check to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 10 and 21600 that represents number of seconds between two health checks.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_interval value
my $value = $object->dns_health_check_interval();

#Modify dns_health_check_interval value
$object->dns_health_check_interval(2000);
```

dns_health_check_recursion_flag( )

Use this method to set or retrieve the flag that indicates whether the recursive DNS health check is enabled or not.

Setting this parameter to defined value, implicitly sets the override_dns_health_check attribute to "true". Setting this parameter to undefined causes the appliance to use the Grid-level DNS health check settings and automatically sets the override_dns_health_check attribute to "false" if following fields are undefined:

```
dns_health_check_domain_list
dns_health_check_anycast_control
dns_health_check_interval
dns_health_check_retries
dns_health_check_timeout
enable_dns_health_check
```

But if any of the fields above contains a value, then the override_dns_health_check attribute is set to "true".

Note that when dns_health_check_recursion_flag contains a value and override_dns_health_check is set to "false", the last operation takes precedence. Thus the sequence $zone->dns_health_check_recursion_flag("true"); $zone->override_dns_health_check("false"); sets override_dns_health_check to "false", and the sequence $zone->override_dns_health_check("false"); $zone->dns_health_check_recursion_flag("true"); sets override_dns_health_check to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable recursive DNS health check queries, and 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_recursion_flag value
my $value = $object->dns_health_check_recursion_flag();
```

```
#Modify dns_health_check_recursion_flag value
$object->dns_health_check_recursion_flag('true');
```

dns_health_check_retries( )

Use this method to set or retrieve the number of DNS health check retries.

Setting this parameter to defined value, implicitly sets the override_dns_health_check attribute to "true". Setting this parameter to undefined causes the appliance to use the Grid-level DNS health check settings and automatically sets the override_dns_health_check attribute to "false" if following fields are undefined:

```
dns_health_check_domain_list
dns_health_check_recursion_flag
dns_health_check_anycast_control
dns_health_check_interval
dns_health_check_timeout
enable_dns_health_check
```

But if any of the fields above contains a value, then the override_dns_health_check attribute is set to "true".

Note that when dns_health_check_retries contains a value and override_dns_health_check is set to "false", the last operation takes precedence. Thus the sequence $zone->dns_health_check_retries("4"); $zone->override_dns_health_check("false"); sets override_dns_health_check to "false", and the sequence $zone->override_dns_health_check("false"); $zone->dns_health_check_retries("4"); sets override_dns_health_check to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_retries value
my $value = $object->dns_health_check_retries();

#Modify dns_health_check_retries value
$object->dns_health_check_retries(2);
```

dns_health_check_timeout( )

Use this method to set or retrieve the DNS health check timeout interval (in seconds).

Setting this parameter to defined value, implicitly sets the override_dns_health_check attribute to "true". Setting this parameter to undefined causes the appliance to use the Grid-level DNS health check settings and automatically sets the override_dns_health_check attribute to "false" if following fields are undefined:

```
dns_health_check_domain_list
dns_health_check_recursion_flag
dns_health_check_anycast_control
dns_health_check_interval
dns_health_check_retries
enable_dns_health_check
```

But if any of the fields above contains a value, then the override_dns_health_check attribute is set to "true".

Note that when dns_health_check_timeout contains a value and override_dns_health_check is set to "false", the last operation takes precedence. Thus the sequence $zone->dns_health_check_timeout("4"); $zone->override_dns_health_check("false"); sets override_dns_health_check to "false", and the sequence $zone->override_dns_health_check("false"); $zone->dns_health_check_timeout("4"); sets override_dns_health_check to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_health_check_timeout value
my $value = $object->dns_health_check_timeout();

#Modify dns_health_check_timeout value
$object->dns_health_check_timeout(10);
```

dns_ip_list( )

Use this method to add or retrieve a list of additional IP addresses on which DNS is enabled for a grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::Member::DNS::IP object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_ip_list value
my $value = $object->dns_ip_list();

#Modify dns_ip_list

#Construct Infoblox::Grid::Member::DNS::IP object

my $ip = Infoblox::Grid::Member::DNS::IP->new(
    member_virtual_ip => '10.0.0.10',
);

$object->dns_ip_list([$ip]);
```

dns64_groups( )

Use this method to set or retrieve the list of DNS64 synthesis groups associated with this member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_dns64 method to "true". Setting the parameter to undefined causes the appliance to use the grid DNS default and automatically resets the override_dns64 method to "false".

Note that when dns64_groups is set to a defined value and override_dns64_groups is set to "false", the last operation takes precedence. Thus the sequence $object->dns64_groups([$group1]); $object->override_dns64("false"); will set override_dns64 to "false", and the sequence $object->override_dns64("false"); $object->dns64_groups([$group1]); will result in override_dns64="true".

Parameter

Valid value is an array reference that contains Infoblox::Grid::DNS::DNS64Group objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the list of DNS64 synthesis groups
my $dns64_groups_list = $memberdns->dns64_groups();

#Modify it
my $group = $session->get(
                          object => "Infoblox::Grid::DNS::DNS64Group"),
                          name => "groupname",
                          prefix => "groupprefix",
                        );
$memberdns->dns64_groups([$group]);
```

dnssec_enabled( )

Use this method to enable/disable the DNSSEC feature.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to enable the DNSSEC feature. Set the parameter to "false" to disable the feature.

Setting this parameter to "true" or "false" implicitly sets the override_dnssec attribute to "true". Setting the parameter to undefined causes the appliance to use the grid-level DNSSEC settings and automatically sets the override_dnssec attribute to "false".

Note that in the case when dnssec_enabled is set to "true"/"false" and override_dnssec is set to "false" simultaneously, the last operation takes precedence. Thus the sequence $grid_member->dnssec_enabled("false"); $grid_member->override_dnssec("false"); will set override_dnssec to "false", and the sequence $grid_member->override_dnssec("false"); $grid_member->dnssec_enabled("false"); will result in override_dnssec="true".

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_enabled
my $dnssec_enabled = $memberdns->dnssec_enabled();
#Modify dnssec_enabled
$memberdns->dnssec_enabled("true");
#Set the value to undefined to inherit grid level settings.
$memberdns->dnssec_enabled(undef);
```

dnssec_expired_signatures_enabled( )

Use this method to control whether the DNS member accepts expired signatures.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to accept expired signatures. Set it to "false" to reject expired signatures.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_expired_signatures_enabled
my $dnssec_expired_signatures_enabled = $memberdns->dnssec_expired_signatures_enabled();
#Modify dnssec_expired_signatures_enabled
$memberdns->dnssec_expired_signatures_enabled("true");
```

dnssec_validation_enabled( )

Use this method to enable or disable DNS security validation.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to enable the validation. Set it to "false" to disable the validation.

The default value of the parameter is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_validation_enabled
my $dnssec_validation_enabled = $memberdns->dnssec_validation_enabled();
#Modify dnssec_validation_enabled
$memberdns->dnssec_validation_enabled("false");
```

dnssec_blacklist_enabled()

Use this method to enable and disable blacklist rules for DNSSEC-enabled clients.

Parameter

Set the parameter to "true" to apply blacklist rules for DNSSEC-enabled clients. Set to "false" to disable them.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_blacklist_enabled
my $dnssec_blacklist_enabled = $memberdns->dnssec_blacklist_enabled();
#Modify dnssec_blacklist_enabled
$memberdns->dnssec_blacklist_enabled("true");
```

dnssec_negative_trust_anchors( )

Use this method to set or retrieve the list of zones for which the appliance does not perform DNSSEC validation.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of strings that contains the lsit of zones for which the appliance does not perform DNSSEC validation.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_negative_trust_anchors value
my $value = $member_dns->dnssec_negative_trust_anchors();
#Modify dnssec_negative_trust_anchors value
$member_dns->dnssec_negative_trust_anchors($zones);
```

dnssec_dns64_enabled()

Use this method to enable and disable DNS64 groups for DNSSEC-enabled clients.

Parameter

Set the parameter to "true" to apply DNS64 groups for DNSSEC-enabled clients. Set to "false" to disable them.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_dns64_enabled
my $dnssec_dns64_enabled = $member_dns->dnssec_dns64_enabled();
#Modify dnssec_dns64_enabled
$member_dns->dnssec_dns64_enabled("true");
```

dnssec_nxdomain_enabled()

Use this method to enable and disable NXDOMAIN rules for DNSSEC-enabled clients.

Parameter

Set the parameter to "true" to apply NXDOMAIN rules for DNSSEC-enabled clients. Set to "false" to disable them.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_nxdomain_enabled
my $dnssec_nxdomain_enabled = $memberdns->dnssec_nxdomain_enabled();
#Modify dnssec_nxdomain_enabled
$memberdns->dnssec_nxdomain_enabled("true");
```

dnssec_rpz_enabled()

Use this method to enable and disable RPZ policies for DNSSEC-enabled clients.

Parameter

Set the parameter to "true" to apply RPZ policies for DNSSEC-enabled clients. Set to "false" to disable them.

The default value of the parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dnssec_rpz_enabled
my $dnssec_rpz_enabled = $memberdns->dnssec_rpz_enabled();
#Modify dnssec_rpz_enabled
$memberdns->dnssec_rpz_enabled("true");
```

dnssec_trusted_keys( )

Use this method to specify the list of trusted keys for the DNSSEC feature.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Array reference that contains a list of Infoblox::DNS::DnssecTrustedKey objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns a reference to a list of the trusted keys.

Example

```
#Get dnssec_trusted_keys
my $dnssec_trusted_keys = $memberdns->dnssec_trusted_keys();
#Modify dnssec_trusted_keys
my $key1=Infoblox::DNS::DnssecTrustedKey->new(
   fqdn => "myzone.com",
   algorithm => "RSAMD5",
   key       => "c2ltcGxlIGtleQo="
   );
$memberdns->dnssec_trusted_keys([$key1]);
```

dns_notify_transfer_source_interface( )

Use this method to specify which IP address is used as the source for DDNS notify and transfer operations.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "VIP", "MGMT", "LAN2", "Any" or an IPV4 address. Default is "VIP".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting dns_source_interface
my $dns_source_interface = $memberdns->dns_source_interface( );
#Modifying dns_source_interface
$memberdns->dns_source_interface("VIP");
```

dns_query_capture_file_time_limit( )

Use this method to set or retrieve the DNS query capture file time (in minutes) limit.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is unsigned integer between 1 and 10. The default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_query_capture_file_time_limit value
my $dns_query_capture_file_time_limit = $object->dns_query_capture_file_time_limit();

#Modify dns_query_capture_file_time_limit value
$object->dns_query_capture_file_time_limit('5');
```

dns_query_source_interface( )

Use this method to specify which IP address is used as the source for DDNS query operations.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "VIP", "MGMT", "LAN2", "Any" or an IPV4 address. Default is "VIP".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting dns_source_interface
my $dns_source_interface = $memberdns->dns_source_interface( );
#Modifying dns_source_interface
$memberdns->dns_source_interface("VIP");
```

dns_view_address_settings( )

Use this method to set or retrieve the list of address settings for Grid member views.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::Member::DNS::ViewAddressSetting objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_view_address_settings value
my $value = $object->dns_view_address_settings();

#Construct view address setting
my $view_address_setting = Infoblox::Grid::Member::DNS::ViewAddressSetting->new('view_name' =>
'view1');
```

```
#Modify dns_view_address_settings value
$object->dns_view_address_settings([$view_address_setting]);
```

domains_to_capture_dns_queries( )

Use this method to set or retrieve the list of domains to capture DNS queries.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains desired domain names in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domains_to_capture_dns_queries value
my $domains_to_capture_dns_queries = $object->domains_to_capture_dns_queries();

#Modify domains_to_capture_dns_queries value
$object->domains_to_capture_dns_queries(['domain1.com', 'domain2.com']);
```

dtc_edns_prefer_client_subnet( )

Use this method to set or retrieve the flag that indicates whether the use of the edns-client-subnet option for DTC is enabled or disabled.

Setting this method to a defined value implicitly sets the override_dtc_edns_prefer_client_subnet method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_dtc_edns_prefer_client_subnet method to "false".

Note that when dtc_edns_prefer_client_subnet is set to a defined value and override_dtc_edns_prefer_client_subnet is set to "false", the last operation takes precedence. Thus the sequence $object->dtc_edns_prefer_client_subnet("true"); $object->override_dtc_edns_prefer_client_subnet("false"); will set override_dtc_edns_prefer_client_subnet to "false", and the sequence $object->override_dtc_edns_prefer_client_subnet("false"); $object->dtc_edns_prefer_client_subnet("true"); will result in override_dtc_edns_prefer_client_subnet="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable use of the edns-client-subnet option for DTC or 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dtc_edns_prefer_client_subnet value
my $dtc_edns_prefer_client_subnet = $object->dtc_edns_prefer_client_subnet();

#Modify dtc_edns_prefer_client_subnet value
$object->dtc_edns_prefer_client_subnet('true');
```

dtc_health_source_interface( )

Use this method to set or retrieve the source address for the health checks.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is one of the following: VIP, MGMT, LAN2, ANY or IPv4 / IPv6 address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting dtc_health_source_interface
my $dtc_source_interface = $memberdns->dtc_health_source_interface();
#Modifying dtc_health_source_interface
$memberdns->dtc_health_source_interface('VIP');
```

enable_blackhole( )

Use this method to enable or disable the blocking of DNS queries. This setting overrides the grid enable_blackhole settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to block DNS queries or "false" to disable blocking DNS queries. The default value is "false".

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_blackhole
my $enable_blackhole = $object->enable_blackhole( );
#Modify enable_blackhole
$memberdns->enable_blackhole("true");
```

enable_blacklist( )

Use this method to enable or disable a blacklist on the grid member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_blacklist flag or "false" to deactivate/unset it. The default is "false".

Setting this parameter to "true" or "false" implicitly sets the override_blacklist attribute to "true". Setting the parameter to undefined causes the appliance to use the grid-level blacklist settings and automatically sets the override_blacklist attribute to "false" if "blacklist_redirect_addresses" is also undefined.

Note that when enable_blacklist is set to "true"/"false" and override_blacklist is set to "false", the last operation takes precedence. Thus the sequence $memberdns->enable_blacklist("false"); $memberdns->override_blacklist("false"); sets override_blacklist to "false", and the sequence $memberdns->override_blacklist("false"); $memberdns->enable_blacklist("false"); sets override_blacklist to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_blacklist
my $enable_blacklist = $memberdns->enable_blacklist( );
#Modifying enable_blacklist
$memberdns->enable_blacklist("true");
```

enable_capture_dns_queries( )

Use this method to set or retrieve the flag that indicates whether the capture of DNS queries is enabled or disabled.

Setting this method to a defined value implicitly sets the override_enable_capture_dns method to "true". Setting the parameter to undefined unless enable_capture_dns_responses is defined causes the appliance to use the Grid DNS default and automatically resets the override_enable_capture_dns method to "false".

Note that when enable_capture_dns_queries is set to a defined value and override_enable_capture_dns is set to "false", the last operation takes precedence. Thus the sequence $object->enable_capture_dns_queries("true"); $object->override_enable_capture_dns("false"); will set override_enable_capture_dns to "false", and the sequence $object->override_enable_capture_dns("false"); $object->enable_capture_dns_queries("true"); will result in override_enable_capture_dns="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the capture of DNS queries or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_capture_dns_queries value
my $enable_capture_dns_queries = $object->enable_capture_dns_queries();

#Modify enable_capture_dns_queries value
$object->enable_capture_dns_queries('true');
```

enable_capture_dns_responses( )

Use this method to set or retrieve the flag that indicates whether the capture of DNS responses is enabled or disabled.

Setting this method to a defined value implicitly sets the override_enable_capture_dns method to "true". Setting the parameter to undefined unless enable_capture_dns_queries is defined causes the appliance to use the Grid DNS default and automatically resets the override_enable_capture_dns method to "false".

Note that when enable_capture_dns_responses is set to a defined value and override_enable_capture_dns is set to "false", the last operation takes precedence. Thus the sequence $object->enable_capture_dns_responses("true"); $object->override_enable_capture_dns("false"); will set override_enable_capture_dns to "false", and the sequence $object->override_enable_capture_dns("false"); $object->enable_capture_dns_responses("true"); will result in override_enable_capture_dns="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the capture of DNS responses or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_capture_dns_responses value
my $enable_capture_dns_responses = $object->enable_capture_dns_responses();

#Modify enable_capture_dns_responses value
$object->enable_capture_dns_responses('true');
```

enable_dns( )

Use this method to enable/disable the DNS service of a member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DNS service or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_dns
$memberdns->enable_dns( );
#Modifying enable_dns
$memberdns->enable_dns("true");
```

enable_dns_cache_acceleration( )

Use this method to enable/disable the DNS Cache Acceleration service of a member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the DNS Cache Acceleration service or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_dns_cache_acceleration
$memberdns->enable_dns_cache_acceleration( );
#Modifying enable_dns_cache_acceleration
$memberdns->enable_dns_cache_acceleration("true");
```

enable_dns_health_check( )

Use this method to set or retrieve the flag that indicates whether the DNS health check is enabled or not.

Setting this parameter to defined value, implicitly sets the override_dns_health_check attribute to "true". Setting this parameter to undefined causes the appliance to use the Grid-level DNS health check settings and automatically sets the override_dns_health_check attribute to "false" if following fields are undefined:

```
dns_health_check_domain_list
dns_health_check_recursion_flag
dns_health_check_anycast_control
dns_health_check_interval
dns_health_check_retries
dns_health_check_timeout
```

But if any of the fields above contains a value, then the override_dns_health_check attribute is set to "true".

Note that when enable_dns_health_check contains a value and override_dns_health_check is set to "false", the last operation takes precedence. Thus the sequence $zone->enable_dns_health_check("true"); $zone->override_dns_health_check("false"); sets override_dns_health_check to "false", and the sequence $zone->override_dns_health_check("false"); $zone->enable_dns_health_check("true"); sets override_dns_health_check to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable DNS health check, and 'false' to disable it.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dns_health_check value
my $value = $object->enable_dns_health_check();

#Modify enable_dns_health_check value
$object->enable_dns_health_check('true');
```

enable_dns64( )

Use this method to enable/disable DNS64 support for this member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_dns64 method to "true". Setting the parameter to undefined causes the appliance to use the grid DNS default and automatically resets the override_dns64 method to "false".

Note that when enable_dns64 is set to a defined value and override_enable_dns64 is set to "false", the last operation takes precedence. Thus the sequence $object->enable_dns64("true"); $object->override_dns64("false"); will set override_dns64 to "false", and the sequence $object->override_dns64("true"); $object->enable_dns64("testdomain"); will result in override_dns64="true".

Parameter

Specify "true" to set the enable_dns64 flag or "false" to deactivate and unset it. The default value is "false".

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method

returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get the enable_dns64 flag
my $enable_dns64 = $memberdns->enable_dns64();
#Modify the enable_dns64 flag
$memberdns->enable_dns64("true");
```

enable_excluded_domain_names( )

Use this method to set or retrieve the flag that indicates whether the excluding domain names captured DNS query and response is enabled or disabled..

Setting this method to a defined value implicitly sets the override_enable_excluded_domain_names method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_enable_excluded_domain_names method to "false".

Note that when enable_excluded_domain_names is set to a defined value and override_enable_excluded_domain_names is set to "false", the last operation takes precedence. Thus the sequence $object->enable_excluded_domain_names("true"); $object->override_enable_excluded_domain_names("false"); will set override_enable_excluded_domain_names to "false", and the sequence $object->override_enable_excluded_domain_names("false"); $object->enable_excluded_domain_names("true"); will result in override_enable_excluded_domain_names="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the excluding domain names from captured DNS query and response or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_excluded_domain_names value
my $enable_excluded_domain_names = $object->enable_excluded_domain_names();

#Modify enable_excluded_domain_names value
$object->enable_excluded_domain_names('true');
```

enable_fixed_rrset_order_fqdns( )

Use this method to enable or disable fixed RRset order for specified FQDNs.

Setting this method to a defined value implicitly sets the override_fixed_rrset_order_fqdns method to "true".

Note that when enable_fixed_rrset_order_fqdns is set to a defined value and override_fixed_rrset_order_fqdns is set to "false", the last operation takes precedence. Thus the sequence $object->enable_fixed_rrset_order_fqdns("true"); $object->override_fixed_rrset_order_fqdns("false"); will set override_fixed_rrset_order_fqdns to "false", and the sequence $object->override_fixed_rrset_order_fqdns("false"); $object->enable_fixed_rrset_order_fqdns("true"); will result in override_fixed_rrset_order_fqdns="true".

The enable_fixed_rrset_order_fqdns attribute can be specified explicitly. It is also set implicitly when fixed_rrset_order_fqdns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable fixed RRset order for specified FQDNs or "false" to disable it.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_fixed_rrset_order_fqdns flag
```

```
my $enable_fixed_rrset_order_fqdns = $member_dns->enable_fixed_rrset_order_fqdns();
#Modify enable_fixed_rrset_order_fqdns flag
$member_dns->enable_fixed_rrset_order_fqdns("true");
```

enable_ftc( )

Use this method to set or retrieve the flag that indicates whether the Fault Tolerant Caching (FTC) feature is enabled or not.

Setting this method to a defined value implicitly sets the override_ftc method to "true". Setting the parameter to undefined if ftc_expired_record_ttl and ftc_expired_record_timeout are also undefined causes the appliance to use the Grid DNS default and automatically resets the override_ftc method to "false".

Note that when enable_ftc is set to a defined value and override_ftc is set to "false", the last operation takes precedence. Thus the sequence $object->enable_ftc("true"); $object->override_ftc("false"); will set override_ftc to "false", and the sequence $object->override_ftc("false"); $object->enable_ftc("true"); will result in override_ftc="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable FTC or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ftc
my $enable_ftc = $memberdns->enable_ftc();
#Modify enable_ftc
$memberdns->enable_ftc('true');
```

enable_gss_tsig( )

Use this method to enable/disable the appliance to receive GSS-TSIG authenticated updates from DHCP clients. You must import the keytab file before you enable this feature. See Infoblox::Session->import_data().

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the the appliance to receive GSS-TSIG authenticated updates or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_gss_tsig
$my $enable_gss_tsig = $memberdns->enable_gss_tsig( );
#Modifying enable_gss_tsig
$session->import_data(
     type        => 'keytab',
     path        => '/infoblox/tests/datasets/gss-tsig-gs.keytab',
     service     => 'dns',
     virtual_ip  => '192.168.1.2');
$memberdns->enable_gss_tsig("true");
```

enable_query_rewrite( )

Use this method to enable or disable DNS query rewrite for this member.

Setting this method to a defined value implicitly sets the override_query_rewrite method to "true". Setting the parameter to undefined causes the appliance to use the grid-level enable_query_rewrite value and automatically resets the override_query_rewrite method to "false".

Note that when enable_query_rewrite is set to a defined value and override_query_rewrite is set to "false", the last operation takes precedence. Thus the sequence $object->enable_query_rewrite("true"); $object->override_query_rewrite("false"); will set override_query_rewrite to "false", and the sequence $object->override_query_rewrite("true"); $object->enable_query_rewrite("testdomain"); will result in override_query_rewrite="true".

Parameter
Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_query_rewrite
$memberdns->enable_query_rewrite( );
#Modify enable_query_rewrite
$memberdns->enable_query_rewrite("true");
```

excluded_domain_names( )

Use this method to set or retrieve the list of domains that are excluded from DNS response and query capturing.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains desired domain names in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get excluded_domain_names value
my $excluded_domain_names = $object->excluded_domain_names();

#Modify excluded_domain_names value
$object->excluded_domain_names(['domain1.com', 'domain2.com']);
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Grid Member DNS object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $memberdns->extattrs();
#Modify extattrs
$memberdns->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a Grid Member DNS object.

This method is read-only. Use the Infoblox::Grid::Member object to set or modify the grid member extensible attributes.

Returns

The method returns the attribute value. Attempting to modify the extensible attributes produces an error.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $memberdns->extensible_attributes();
```

facility( )

Use this method to specify a syslog facility. This is the location on the syslog server to which you want to sort the DNS logging messages.

This setting overrides the grid logging facility settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Values are: "daemon", "local0", "local1", "local2", "local3", "local4", "local5", "local6", and "local7".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get facility
$memberdns->facility( );
#Modify facility
$memberdns->facility("local0");
```

file_transfer_setting( )

Use this method to set or retrieve the DNS capture file transfer settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::FileTransferSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get file_transfer_setting value
my $file_transfer_setting = $object->file_transfer_setting();

#Modify file_transfer_setting value
$object->file_transfer_setting($file_transfer);
```

filter_aaaa( )

Use this method to set or retrieve the type of AAAA filtering for this member DNS object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Specifying values in this parameter, such as "YES", implicitly sets the override_filter_aaaa attribute to "true". Setting this parameter and the "filter_aaaa" attribute to undefined causes the appliance to use the grid-level filter_aaaa settings and automatically sets the override_filter_aaaa attribute to "false". But if the "filter_aaaa" attribute contains a value, then the override_filter_aaaa attribute is set to "true".

Note that when filter_aaaa contains a valid value and override_filter_aaaa is set to "false", the last operation takes precedence. Thus the sequence $memberdns->filter_aaaa("YES"); $memberdns->override_filter_aaaa("false"); sets override_filter_aaaa to "false", and the sequence $memberdns->override_filter_aaaa("false"); $memberdns->filter_aaaa("true"); sets override_filter_aaaa to "true".

Parameter

Valid values are "YES", "NO" and "BREAK_DNSSEC". The default value is "NO".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the filter aaaa type
my $filter_aaaa = $memberdns->filter_aaaa();
#Modify the filtering
$memberdns->filter_aaaa("YES");
```

filter_aaaa_list( )

Use this method to set or retrieve the list of IPv4 addresses and networks from which queries are received. AAAA filtering is applied to these addresses. This setting overrides the grid filter_aaaa_list if override_filter_aaaa is set to "true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Specifying values in this parameter, such as ["10.0.0.10", "10.0.0.20"] or [], implicitly sets the override_filter_aaaa attribute to "true". Setting this parameter and the "filter_aaaa" attribute to undefined causes the appliance to use the grid-level filter_aaaa settings and automatically sets the override_filter_aaaa attribute to "false". But if the "filter_aaaa" attribute contains a value, then the override_filter_aaaa attribute is set to "true".

Note that when filter_aaaa_list contains a valid array reference and override_filter_aaaa is set to "false", the last operation takes precedence. Thus the sequence $memberdns->filter_aaaa_list(["10.0.0.10", "10.0.0.20"]); $memberdns->override_filter_aaaa("false"); sets override_filter_aaaa to "false", and the sequence $memberdns->override_filter_aaaa("false"); $memberdns->filter_aaaa_list(["10.0.0.10", "10.0.0.20"]); sets override_filter_aaaa to "true".

Parameter

A valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4 addresses and networks. To return AAAA records for queries received from an IPv4 client, add "!" as the prefix to the IP addresses and networks. Specify "any" to allow AAAA records to be returned for any query received by an IPv4 client.

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Getting filter_aaaa_list
my $filter_aaaa_list = $memberdns->filter_aaaa_list( );
#Modifying filter_aaaa_list
$memberdns->filter_aaaa_list(["any"]);
#Modifying filter_aaaa_list
$memberdns->filter_aaaa_list(["10.0.0.10", "20.0.0.0/24", "!"."30.0.0.30", "!"."40.10.0.0/24"]);
#Use Grid::DNS level filter_aaaa_list
$memberdns->filter_aaaa_list(undef);
$memberdns->enable_filter_aaaa(undef);
#Use Infoblox::Grid::NamedACL
$memberdns->filter_aaaa_list($nacl);
```

fixed_rrset_order_fqdns( )

Use this method to set or retrieve configuration for fixed RRSET order for specified FQDNs.

Setting this method to a defined value implicitly sets the enable_fixed_rrset_order_fqdns and override_fixed_rrset_order_fqdns methods to "true". Setting the parameter to undefined causes the appliance to disable fixed RRset order of FQDNs and automatically resets the enable_fixed_rrset_order_fqdns method to "false".

Note that when fixed_rrset_order_fqdns is set to a defined value and enable_fixed_rrset_order_fqdns is set to "false", the last operation takes precedence. Thus the sequence $object->fixed_rrset_order_fqdns($fqdns); $object->enable_fixed_rrset_order_fqdns("false"); will set enable_fixed_rrset_order_fqdns to "false", and the sequence $object->enable_fixed_rrset_order_fqdns("false"); $object->fixed_rrset_order_fqdns($fqdns); will result in enable_fixed_rrset_order_fqdns="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::DNS::FixedRRSetOrderFQDN objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the fixed_rrset_order_fqdns list
my $fixed_rrset_order_fqdns = $member_dns->fixed_rrset_order_fqdns();
#Modify the fixed_rrset_order_fqdns list
$member_dns->fixed_rrset_order_fqdns([$fqdn1, $fqdn2]);
```

forwarders( )

Use this method to specify forwarders for the member. A forwarder is essentially a name server to which other name servers first send all

of their off-site queries. The forwarder builds up a cache of information, avoiding the need for the other name servers to send queries off-site. This setting overrides the grid-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::DNS::Member, Infoblox::DNS::Nameserver object(s), or IP addresses.

Specifying values in this parameter, such as ["10.0.0.10", "10.0.0.20"] or [], implicitly sets the override_forwarders attribute to "true". Setting this parameter and the "forward_only" attribute to undefined causes the appliance to use the grid-level forwarders settings and automatically sets the override_forwarders attribute to "false". But if the "forward_only" attribute contains a value, then the override_forwarders attribute is set to "true".

Note that when forwarders_redirect_addresses contains a valid array reference and override_forwarders is set to "false", the last operation takes precedence. Thus the sequence $memberdns->forwarders(["10.0.0.10", "10.0.0.20"]); $memberdns->override_forwarders("false"); sets override_forwarders to "false", and the sequence $memberdns->override_forwarders("false"); $memberdns->forwarders(["10.0.0.10", "10.0.0.20"]); sets override_forwarders to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting forwarders
$memberdns->forwarders( );
#Modifying forwarders
$memberdns->forwarders( [ "10.0.0.10" ] );
```

forward_only( )

Use this method to configure this member to send queries to forwarders only. When the value is "true", the member sends queries to forwarders only, and not to other internal or Internet root servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable forward only or "false" to desable it. Default is "false"

Setting this parameter to "true" or "false" implicitly sets the override_forwarders attribute to "true". Setting the parameter to undefined causes the appliance to use the grid-level forwarders settings and automatically sets the override_forwarders attribute to "false", if "forwarders" is also undefined.

Note that when forward_only is set to "true"/"false" and override_forwarders is set to "false", the last operation takes precedence. Thus the sequence $memberdns->forward_only("false"); $memberdns->override_forwarders("false"); sets override_forwarders to "false", and the sequence $memberdns->override_forwarders("false"); $memberdns->forward_only("false"); sets override_forwarders to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting forward_only
$memberdns->forward_only( );
#Modifying forward_only
$memberdns->forward_only("true");
```

forward_updates( )

Use this method to allow/disallow secondary servers to forward updates to the DNS server. This setting overrides grid update settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable forward updates or "false" desable it. Default is "false"

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting forward_updates
$memberdns->forward_updates( );
#Modifying forward_only
$memberdns->forward_updates("true");
```

ftc_expired_record_ttl( )

Use this method to set or retrieve the TTL value of the expired Fault Tolerant Caching (FTC) record in the DNS responses.

Setting this method to a defined value implicitly sets the override_ftc method to "true". Setting the parameter to undefined if enable_ftc and ftc_expired_record_timeout are also undefined causes the appliance to use the Grid DNS default and automatically resets the override_ftc method to "false".

Note that when ftc_expired_record_ttl is set to a defined value and override_ftc is set to "false", the last operation takes precedence. Thus the sequence $object->ftc_expired_record_ttl("true"); $object->override_ftc("false"); will set override_ftc to "false", and the sequence $object->override_ftc("false"); $object->ftc_expired_record_ttl("true"); will result in override_ftc="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the TTL in seconds. The default value is 5.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ftc_expired_record_ttl
my $ftc_expired_record_ttl = $memberdns->ftc_expired_record_ttl( );
#Modify ftc_expired_record_ttl
$memberdns->ftc_expired_record_ttl(60);
```

ftc_expired_record_timeout( )

Use this method to set or retrieve the timeout value after which the expired Fault Tolerant Caching (FTC) record becomes stale and is no longer valid.

Setting this method to a defined value implicitly sets the override_ftc method to "true". Setting the parameter to undefined if ftc_expired_record_ttl and enable_ftc are also undefined causes the appliance to use the Grid DNS default and automatically resets the override_ftc method to "false".

Note that when ftc_expired_record_timeout is set to a defined value and override_ftc is set to "false", the last operation takes precedence. Thus the sequence $object->ftc_expired_record_timeout("true"); $object->override_ftc("false"); will set override_ftc to "false", and the sequence $object->override_ftc("false"); $object->ftc_expired_record_timeout("true"); will result in override_ftc="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the timeout in seconds. The default value is 86400.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ftc_expired_record_timeout
my $ftc_expired_record_timeout = $memberdns->ftc_expired_record_timeout( );
#Modify ftc_expired_record_timeout
$memberdns->ftc_expired_record_timeout(3600);
```

glue_record_addresses( )

Use this method to specify which IP address the appliance uses when it generates the glue record. It can use the IP address of the appliance, the NAT IP address, or an IP address that you define.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::DNS::GlueRecordAddr object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $glue_record_addr1 = Infoblox::DNS::GlueRecordAddr->new(
    view                => "default",  #can only be one of existing views
    glue_record_address => "NAT",
);
$memberdns->glue_record_addresses([$glue_record_addr1]);
```

gss_tsig_keys( )

Use this method to set or retrieve the list of GSS-TSIG keys for a member DNS object.

Setting this method to a defined value implicitly sets the override_gss_tsig_keys method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_gss_tsig_keys method to "false".

Note that when gss_tsig_keys is set to a defined value and override_gss_tsig_keys is set to "false", the last operation takes precedence. Thus the sequence $object->gss_tsig_keys($keys); $object->override_gss_tsig_keys("false"); will set override_gss_tsig_keys to "false", and the sequence $object->override_gss_tsig_keys("false"); $object->gss_tsig_keys($keys); will result in override_gss_tsig_keys="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::KerberosKey objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the Kerberos keys list
my $kerberos_keys_list = $memberdns->gss_tsig_keys();
#Modify the Kerberos keys list
my $kerberos_key1 = Infoblox::Cluster::KerberosKey->new(
       principal => 'host/appliance.ivan.test1@LADYBUG.LOCAL',
       );
my $kerberos_key2 = Infoblox::Cluster::KerberosKey->new(
       principal => 'host/appliance.ivan.test2@LADYBUG.LOCAL',
       );
$memberdns->gss_tsig_keys([$kerberos_key1, $kerberos_key2]);
```

host_name_restriction_policy( )

Use this method to set or retrieve the member-level host name restriction policy that overrides the grid-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is the name of record name policy defined at the grid level via Infoblox::Grid::RecordNamePolicy

There are three predefined policies:

Policy Name Regex Applied

"Allow Any" .+

"Allow Underscore" ^[-a-zA-Z0-9_.]+$

"Strict Hostname Checking" ^[a-zA-Z0-9]$|^[a-zA-Z0-9][-a-zA-Z0-9.]*[a-zA-Z0-9]$

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting host_name_restriction_policy
$memberdns->host_name_restriction_policy( );
#Modifying host_name_restriction_policy
$memberdns->host_name_restriction_policy("Allow Any");
#Un-override host_name_restriction_policy
$memberdns->host_name_restriction_policy(undef);
```

ipv6_glue_record_addresses( )

Use this method to specify which IPv6 address the appliance uses when it generates the glue record. It can use the IPv6 address of the appliance, the NAT IPv6 address, or an IPv6 address that you define.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array of Infoblox::DNS::GlueRecordAddr objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $v6_glue_record_addr1 = Infoblox::DNS::GlueRecordAddr->new(
    view                => "default",  #can only be one of existing views
    glue_record_address => "2001:db8::1",
);

$memberdns->ipv6_glue_record_addresses([$v6_glue_record_addr1]);
```

is_unbound_capable( )

Use this method to retrieve the flag that indicates whether Member DNS supports unbound recursive resolver or not. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get is_unbound_capable
my $is_unbound_capable = $memberdns->is_unbound_capable();
```

lame_ttl( )

Use this method to set or retrieve the number of seconds to cache lame delegations or lame servers.

Parameter

The number of seconds to cache lame delegations or lame servers. The default value is 600.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lame_ttl
my $lame_ttl = $memberdns->lame_ttl();
#Modify lame_ttl
$memberdns->lame_ttl(700);
```

logging_categories( )

Use this method to set logging categories for this member. This setting overrides grid logging category settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains one or more of the following values:

"general": Records the BIND messages that are not specifically classified.

"config": Records the configuration file parsing messages.

"dnssec": Records the DNSSEC-signed responses.

"network": Records the network operation messages.

"queries": Records the query messages.

"responses": Records the response messages.

"security": Records the approved and denied requests.

"xfer-in": Records zone transfer messages from the remote name servers to the appliance.

"xfer-out": Records zone transfer messages from the Infoblox appliance to remote name servers.

"update": Records the dynamic update instances.

"resolver": Records the DNS resolution instances, including recursive queries from resolvers.

"notify": Records the asynchronous zone change notification messages.

"lame_servers": Records bad delegation instances.

"database": Records BIND's internal database processes.

"client": Records client requests.

"rpz": Records RPZ messages.

"dtc_gslb": Records DTC GSLB activity.

"dtc_health": Records DTC health monitoring.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting logging_categories
$memberdns->logging_categories( );
#Modifying logging_categories
$memberdns->logging_categories( [ "general", "database" , "queries" ] );
```

max_cache_ttl( )

Use this method to set or retrieve the maximum time (in seconds) for which the server will cache positive answers.

Parameter

The maximum time is specified in seconds. The default value is 604800.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_cache_ttl
my $max_cache_ttl = $memberdns->max_cache_ttl();
#Modify max_cache_ttl
$memberdns->max_cache_ttl(400);
```

max_ncache_ttl( )

Use this method to set or retrieve the maximum time (in seconds) for which the server will cache negative (NXDOMAIN) responses. This method applies for the defined member configuration.

Parameter

The maximum time is specified in seconds. The default value is 10800. The maximum allowed value is 604800.

Setting this parameter implicitle sets the override_max_ncache_ttl attribute to "true". Setting the parameter to undefined causes the appliance to use the Grid-level settings and automatically sets the override_max_ncache_ttl attribute to "false".

Note that when max_ncache_ttl is set and override_max_ncache_ttl is set to "false", the last operation takes precedence. Thus the sequence $firstview->max_ncache_ttl(10800); $firstview->override_max_ncache_ttl("false"); sets override_max_ncache_ttl to "false", and the sequence $firstview->override_max_ncache_ttl("false"); $firstview->max_ncache_ttl(30600); sets override_max_ncache_ttl to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_ncache_ttl
my $max_ncache_ttl = $memberdns->max_ncache_ttl();
#Modify max_ncache_ttl
$memberdns->max_ncache_ttl(400);
```

max_cached_lifetime( )

Use this method to set or retrieve maximum time in seconds a DNS response can be stored in the hardware acceleration cache.

Parameter

Valid values are unsigned integer between 60 and 86400, inclusive. Default value is 86400.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_cached_lifetime
my $max_cached_lifetime = $memberdns->max_cached_lifetime();
#Modify max_cached_lifetime
$memberdns->max_cached_lifetime(400);
```

minimal_resp( )

Use this method to enable/disable the ability to return a minimal amount of data in response to a query. This capability speeds up the DNS services provided by the appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable minimal responses or "false" to desable it. Default is "true"

Returns

If you specified a parameter, the method returns 1 when the modification succeeds, and returns other values when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting minimal_resp
$memberdns->minimal_resp( );
#Modifying minimal_resp
$memberdns->minimal_resp("true");
```

name( )

Use this method to retrieve the grid name.

Parameter

None.

Returns

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $memberdns->name();
```

notify_delay( )

Use this method to specify with how many seconds of delay the notify messages are sent to secondaries.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are unsigned integer between 5 and 86400, inclusive. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting notify_delay
my $notify_delay = $memberdns->notify_delay( );
#Modifying notify_delay
$memberdns->notify_delay(5);
```

notify_source_port( )

Use this method to specify the source port for notify messages. When requesting zone transfers from the primary server, some secondary DNS servers use the source port number (the primary server used to send the notify message) as the destination port number in the zone transfer request. This setting overrides grid static source port settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Source port number for notify messages. Valid values are between 1 and 63999. The default is picked by BIND.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting notify_source_port
$memberdns->notify_source_port( );
#Modifying notify_source_port
$memberdns->notify_source_port("2");
```

override_attack_mitigation( )

The override_attack_mitigation attribute controls whether the attack_mitigation method values of the member are used, instead of the Grid default.

The override_attack_mitigation attribute can be specified explicitly. It is also set implicitly when attack_mitigation is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for attack_mitigation. Set the parameter to "false" to inherit the Grid-level setting for attack_mitigation.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_attack_mitigation
my $override_attack_mitigation = $memberdns->override_attack_mitigation( );
#Modifying override_attack_mitigation
$memberdns->override_attack_mitigation("true");
```

override_auto_blackhole( )

The override_auto_blackhole attribute controls whether the auto_blackhole method values of the member are used, instead of the Grid default.

The override_auto_blackhole attribute can be specified explicitly. It is also set implicitly when auto_blackhole is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for auto_blackhole. Set the parameter to "false" to inherit the Grid-level setting for auto_blackhole.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_auto_blackhole
my $override_auto_blackhole = $memberdns->override_auto_blackhole( );
#Modifying override_auto_blackhole
$memberdns->override_auto_blackhole("true");
```

override_bind_hostname_directive( )

The override_bind_hostname_directive attribute controls whether the bind_hostname_directive method values of the member are used, instead of the Grid default.

The override_bind_hostname_directive attribute can be specified explicitly. It is also set implicitly when bind_hostname_directive is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for bind_hostname_directive. Set the parameter to "false" to inherit the Grid-level setting for bind_hostname_directive.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_bind_hostname_directive
my $override_bind_hostname_directive = $memberdns->override_bind_hostname_directive( );
#Modifying override_bind_hostname_directive
$memberdns->override_bind_hostname_directive("true");
```

override_server_id_directive( )

The override_server_id_directive attribute controls whether the server_id_directive method values of the member are used, instead of the Grid default.

The override_server_id_directive attribute can be specified explicitly. It is also set implicitly when server_id_directive is set to a defined

value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for server_id_directive. Set the parameter to "false" to inherit the Grid-level setting for server_id_directive.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_server_id_directive
my $override_server_id_directive = $memberdns->override_server_id_directive( );
#Modifying override_server_id_directive
$memberdns->override_server_id_directive("true");
```

override_capture_dns_queries_on_all_domains( )

The override_capture_dns_queries_on_all_domains attribute controls whether the capture_dns_queries_on_all_domains method values of the member are used, instead of the Grid default.

The override_capture_dns_queries_on_all_domains attribute can be specified explicitly. It is also set implicitly when capture_dns_queries_on_all_domains is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for capture_dns_queries_on_all_domains. Set the parameter to "false" to inherit the Grid-level setting for capture_dns_queries_on_all_domains.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
 #Get override_capture_dns_queries_on_all_domains value
 my $override_capture_dns_queries_on_all_domains = $object-
>override_capture_dns_queries_on_all_domains();

 #Modify override_capture_dns_queries_on_all_domains value
 $object->override_capture_dns_queries_on_all_domains("true");
```

override_copy_xfer_to_notify( )

The override_copy_xfer_to_notify attribute controls whether the copy_xfer_to_notify method values of the member are used, instead of the grid default.

The override_copy_xfer_to_notify attribute can be specified explicitly. It is also set implicitly when copy_xfer_to_notify is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for copy_xfer_to_notify. Set the parameter to "false" to inherit the grid-level setting for copy_xfer_to_notify.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_copy_xfer_to_notify
my $override_copy_xfer_to_notify = $memberdns->override_copy_xfer_to_notify( );
#Modifying override_copy_xfer_to_notify
$memberdns->override_copy_xfer_to_notify("true");
```

override_disable_edns( )

The override_disable_edns attribute controls whether the disable_edns method values of the member are used, instead of the Grid default.

The override_disable_edns attribute can be specified explicitly. It is also set implicitly when disable_edns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for disable_edns. Set the parameter to "false" to inherit the grid-level setting for disable_edns. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_disable_edns
my $override_disable_edns = $memberdns->override_disable_edns();
#Modify override_disable_edns
$memberdns->override_disable_edns("true");
```

override_dns64( )

The override_dns64 attribute controls whether the DNS64 method values of the member are used, instead of the grid default.

The override_dns64 attribute can be specified explicitly. It is also set implicitly when enable_dns64 or dns64_groups are set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_dns64 and dns64_groups. Set the parameter to "false" to inherit the grid-level setting for enable_dns64 and dns64_groups.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_dns64
my $override_dns64=$memberdns->override_dns64( );
#Modifying override_dns64
$memberdns->override_dns64("true");
```

override_dns_health_check( )

The override_dns_health_check attribute controls whether the DNS health check settings Member are used, instead of the Grid default.

The override_dns_health_check attribute can be specified explicitly. It is also set implicitly when following fields are set to a defined value:

```
dns_health_check_domain_list
dns_health_check_recursion_flag
dns_health_check_anycast_control
dns_health_check_interval
dns_health_check_retries
dns_health_check_timeout
enable_dns_health_check
```

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to override the Grid-level DNS health check setting or 'false' to inherit the Grid-level DNS health check setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_dns_health_check value
my $value = $object->override_dns_health_check();

#Modify override_dns_health_check value
$object->override_dns_health_check('true');
```

override_filter_aaaa( )

The override_filter_aaaa attribute controls whether the AAAA filter method values of the member are used, instead of the grid default.

The override_filter_aaaa attribute can be specified explicitly. It is also set implicitly when filter_aaaa or filter_aaaa_list are set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for filter_aaaa and filter_aaaa_list. Set the parameter to "false" to inherit the grid-level setting for filter_aaaa and filter_aaaa_list.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_filter_aaaa
my $override_filter_aaaa=$memberdns->override_filter_aaaa( );
#Modifying override_filter_aaaa
$memberdns->override_filter_aaaa("true");
```

override_dns_cache_acceleration_ttl( )

The override_dns_cache_acceleration_ttl attribute controls whether the dns_cache_acceleration_ttl method values of the member are used, instead of the grid default.

The override_dns_cache_acceleration_ttl attribute can be specified explicitly. It is also set implicitly when dns_cache_acceleration_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for dns_cache_acceleration_ttl. Set the parameter to "false" to inherit the grid-level setting for dns_cache_acceleration_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_dns_cache_acceleration_ttl
my $override_dns_cache_acceleration_ttl=$memberdns->override_dns_cache_acceleration_ttl( );
#Modifying override_dns_cache_acceleration_ttl
$memberdns->override_dns_cache_acceleration_ttl("true");
```

override_ftc( )

The override_ftc attribute controls whether the values of the Fault Tolerant Caching (FTC) feature are used for the member, instead of the

Grid default.

The override_ftc attribute can be specified explicitly. It is also set implicitly when the following fields are set to a defined value:

```
enable_ftc
ftc_expired_record_ttl
ftc_expired_record_timeout
```

Parameter

Set the parameter to "true" to override the Grid-level setting for FTC feature. Set the parameter to "false" to inherit the Grid-level setting for FTC. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ftc
my $override_ftc = $memberdns->override_ftc();
#Modify override_ftc
$memberdns->override_ftc('true');
```

override_gss_tsig_keys( )

The override_gss_tsig_keys attribute controls whether the gss_tsig_keys method values for the member are used, instead of the Grid default.

The override_gss_tsig_keys attribute can be specified explicitly. It is also set implicitly when gss_tsig_keys is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override GSS-TSIG keys. Set the parameter to "false" to inherit the grid-level GSS-TSIG keys.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_gss_tsig_keys
my $override_gss_tsig_keys = $memberdns->override_gss_tsig_keys();
#Modyfying override_gss_tsig_keys
$memberdns->override_gss_tsig_keys("true");
```

override_enable_capture_dns( )

The override_enable_capture_dns attribute controls whether the enable_capture_dns_queries and enable_capture_dns_responses method values of the member are used, instead of the Grid default.

The override_enable_capture_dns attribute can be specified explicitly. It is also set implicitly when enable_capture_dns_queries or enable_capture_dns_responses is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for enable_capture_dns_queries and enable_capture_dns_responses. Set the parameter to "false" to inherit the Grid-level setting for enable_capture_dns_queries and enable_capture_dns_responses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_capture_dns value
my $override_enable_capture_dns = $object->override_enable_capture_dns();
```

```
#Modify override_enable_capture_dns value
$object->override_enable_capture_dns("true");
```

override_enable_excluded_domain_names( )

The override_enable_excluded_domain_names attribute controls whether the capture_dns_queries_on_all_domains method values of the member are used, instead of the Grid default.

The override_enable_excluded_domain_names attribute can be specified explicitly. It is also set implicitly when capture_dns_queries_on_all_domains is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for capture_dns_queries_on_all_domains. Set the parameter to "false" to inherit the Grid-level setting for capture_dns_queries_on_all_domains.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_excluded_domain_names value
my $override_enable_excluded_domain_names = $object->override_enable_excluded_domain_names();

#Modify override_enable_excluded_domain_names value
$object->override_enable_excluded_domain_names("true");
```

override_enable_gss_tsig( )

The override_enable_gss_tsig attribute controls whether the enable_gss_tsig method value for the member is used, instead of the Grid default.

The override_enable_gss_tsig attribute can be specified explicitly. It is also set implicitly when enable_gss_tsig is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_gss_tsig. Set the parameter to "false" to inherit the grid-level setting for enable_gss_tsig value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_gss_tsig
my $override_enable_gss_tsig = $memberdns->override_enable_gss_tsig();
#Modyfying override_enable_gss_tsig
$memberdns->override_enable_gss_tsig("true");
```

override_max_cache_ttl( )

The override_max_cache_ttl attribute controls whether the max_cache_ttl method values of the member are used, instead of the grid default.

The override_max_cache_ttl attribute can be specified explicitly. It is also set implicitly when max_cache_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for max_cache_ttl. Set the parameter to "false" to inherit the grid-level setting for max_cache_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_max_cache_ttl
my $override_max_cache_ttl = $memberdns->override_max_cache_ttl( );
#Modifying override_max_cache_ttl
$memberdns->override_max_cache_ttl("true");
```

override_max_ncache_ttl( )

The override_max_ncache_ttl attribute controls whether the max_ncache_ttl method values of the member are used, instead of the Grid default.

The override_max_ncache_ttl attribute can be specified explicitly. It is also set implicitly when max_ncache_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for max_ncache_ttl. Set the parameter to "false" to inherit the Grid-level setting for max_ncache_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_max_ncache_ttl
my $override_max_ncache_ttl = $memberdns->override_max_ncache_ttl( );
#Modifying override_max_ncache_ttl
$memberdns->override_max_ncache_ttl("true");
```

override_max_cached_lifetime( )

The override_max_cached_lifetime attribute controls whether the max_cached_lifetime method values of the member are used, instead of the grid default.

The override_max_cached_lifetime attribute can be specified explicitly. It is also set implicitly when max_cached_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for max_cached_lifetime. Set the parameter to "false" to inherit the grid-level setting for max_cached_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_max_cached_lifetime
my $override_max_cached_lifetime = $memberdns->override_max_cached_lifetime( );
#Modifying override_max_cached_lifetime
$memberdns->override_max_cached_lifetime("true");
```

override_nxdomain_redirect( )

The "override_nxdomain_redirect" attribute controls whether the "nxdomain_redirect", "nxdomain_redirect_addresses", "nxdomain_redirect_addresses_ipv6", "nxdomain_redirect_ttl", "nxdomain_log_query", and "nxdomain_rulesets" values for this member are used. Note that these values can be overridden at the DNS view level as well.

The "override_nxdomain_redirect" attribute can be specified explicitly. It is also set implicitly as follows: "nxdomain_redirect" => "true"|"false" or "nxdomain_redirect_addresses" => ["10.0.0.10", "10.0.0.20"]|[] or "nxdomain_redirect_addresses" => ["2001:db8::1",

"2002:ffff::1"]|[] result in "override_nxdomain_redirect" => "true", "nxdomain_redirect" => undef and "nxdomain_redirect_addresses" => undef and "nxdomain_redirect_addresses_ipv6" => undef result in "override_nxdomain_redirect" => "false". If "override_nxdomain_redirect" is specified explicitly as "true", and "nxdomain_redirect" => undef, "nxdomain_redirect_addresses" => undef and "nxdomain_redirect_addresses_ipv6" => undef, then the explicit value takes precedence; and "override_nxdomain_redirect"=>"true", "nxdomain_redirect", "nxdomain_redirect_addresses", and "nxdomain_redirect_addresses" remain unchanged in the database.

Specifying the "nxdomain_redirect_ttl", "nxdomain_log_query", or "nxdomain_rulesets" attributes does not affect the "override_nxdomain_redirect" value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting of the NXDOMAIN redirection attributes. Set the parameter to "false" to inherit the grid-level settings.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_nxdomain_redirect
my $override_nxdomain_redirect=$memberdns->override_nxdomain_redirect( );
#Modify override_nxdomain_redirect
$memberdns->override_nxdomain_redirect("true");
```

override_lame_ttl( )

Use this method to set or retrieve the override_lame_ttl attribute that controls whether the lame_ttl method values of the member are used, instead of the Grid default

Parameter

Set the parameter to "true" to override the grid-level setting for lame_ttl. Set the parameter to "false" to inherit the grid-level setting for lame_ttl. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_lame_ttl
my $override_lame_ttl = $memberdns->override_lame_ttl();
#Modify override_lame_ttl
$memberdns->override_lame_ttl('true');
```

override_rpz_qname_wait_recurse( )

The override_rpz_qname_wait_recurse attribute controls whether the rpz_qname_wait_recurse method value for the member is used, instead of the Grid default.

The "override_rpz_qname_wait_recurse" attribute can be specified explicitly. It is also established implicitly as follows: "rpz_qname_wait_recurse" => "true"|"false" results in "override_rpz_qname_wait_recurse" => "true"; "rpz_qname_wait_recurse" => undef results in "override_rpz_qname_wait_recurse" => "false"; If "override_rpz_qname_wait_recurse" is specified explicitly as "true", while "rpz_qname_wait_recurse"=>undef, the explicit value takes precedence, and "override_rpz_qname_wait_recurse"=>"true" while "rpz_qname_wait_recurse" remains unchanged in the database.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for rpz_qname_wait_recurse. Set the parameter to "false" to inherit the Grid-level setting for rpz_qname_wait_recurse value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_rpz_qname_wait_recurse
my $override_rpz_qname_wait_recurse = $memberdns->override_rpz_qname_wait_recurse();
#Modyfying override_rpz_qname_wait_recurse
$memberdns->override_rpz_qname_wait_recurse("true");
```

override_transfers_in( )

Use this method to set or retrieve the override_transfers_in attribute that controls whether the transfers_in method values of the member are used, instead of the Grid default.

Parameter

Set the parameter to "true" to override the grid-level setting for transfers_in. Set the parameter to "false" to inherit the grid-level setting for transfers_in. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_transfers_in
my $override_transfers_in = $memberdns->override_transfers_in();
#Modify override_transfers_in
$memberdns->override_transfers_in('true');
```

override_transfers_out( )

Use this method to set or retrieve the override_transfers_out attribute that controls whether the transfers_out method values of the member are used, instead of the Grid default.

Parameter

Set the parameter to "true" to override the grid-level setting for transfers_out. Set the parameter to "false" to inherit the grid-level setting for transfers_out. The default value is '

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_transfers_out
my $override_transfers_out = $memberdns->override_transfers_out();
#Modify override_transfers_out
$memberdns->override_transfers_out('true');
```

override_transfers_per_ns( )

Use this method to set or retrieve the transfers_per_ns attribute that controls whether the transfers_per_ns method values of the member are used, instead of the Grid default.

Parameter

Set the parameter to "true" to override the grid-level setting for transfers_per_ns. Set the parameter to "false" to inherit the grid-level setting for transfers_per_ns. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_transfers_per_ns
my $override_transfers_per_ns = $memberdns->override_transfers_per_ns();
#Modify override_transfers_per_ns
$memberdns->override_transfers_per_ns('true');
```

override_serial_query_rate( )

Use this method to set or retrieve the override_serial_query_rate attribute that controls whether the serial_query_rate method values of the member are used, instead of the Grid default.

Parameter

Set the parameter to "true" to override the grid-level setting for serial_query_rate. Set the parameter to "false" to inherit the grid-level setting for serial_query_rate. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_serial_query_rate
my $override_serial_query_rate = $memberdns->override_serial_query_rate();
#Modify override_serial_query_rate
$memberdns->override_serial_query_rate('true');
```

override_query_rewrite( )

Use this method to set or retrieve the override_query_rewrite that controls whether the enable_query_rewrite method values of the member are used, instead of the grid-level enable_query_rewrite value.

Parameter

Set the parameter to "true" to override the grid-level DNS query rewrite settings. Set the parameter to "false" to inherit the grid-level DNS query rewrite settings. The default is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_query_rewrite
my $override_query_rewrite = $memberdns->override_query_rewrite();
#Modify override_query_rewrite
$memberdns->override_query_rewrite("true");
```

nxdomain_redirect( )

Use this method to enable or disable NXDOMAIN redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the nxdomain_redirect flag or "false" to deactivate/unset it. The default is "false".

Setting this parameter to "true" or "false" implicitly sets the override_nxdomain_redirect attribute to "true". Setting the parameter to undefined causes the appliance to use the grid-level NXDOMAIN redirection settings and automatically sets the override_nxdomain_redirect attribute to "false" if nxdomain_redirect_addresses or nxdomain_redirect_addresses_ipv6 is also undefined. But if nxdomain_redirect_addresses or nxdomain_redirect_addresses_ipv6 contains a value, then the override_nxdomain_redirect attribute is set to true.

Note that when nxdomain_redirect is set to "true"/"false" and override_nxdomain_redirect is set to "false", the last operation takes precedence. Thus the sequence $grid_member->nxdomain_redirect("false"); $grid_member->override_nxdomain_redirect("false"); sets override_nxdomain_redirect to "false", and the sequence $grid_member->override_nxdomain_redirect("false"); $grid_member->nxdomain_redirect("false"); sets override_nxdomain_redirect to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting nxdomain_redirect
my $nxdomain_redirect = $grid_member->nxdomain_redirect( );
#Modifying nxdomain_redirect
$grid_member->nxdomain_redirect("true");
```

nxdomain_redirect_addresses( )

Use this method to set the NXDOMAIN redirection addresses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of IPv4 addresses. The default value is undefined.

Setting this parameter to a defined value implicitly sets the override_nxdomain_redirect attribute to "true". Setting the parameter to undefined causes the appliance to use the grid-level NXDOMAIN redirection settings and automatically sets the override_nxdomain_redirect attribute to "false" if nxdomain_redirect and nxdomain_redirect_addresses_ipv6 is also undefined. But if nxdomain_redirect or nxdomain_redirect_addresses_ipv6 contains a value, then the override_nxdomain_redirect attribute is set to true.

Note that when nxdomain_redirect_addresses contains a valid array reference and override_nxdomain_redirect is set to "false", the last operation takes precedence. Thus the sequence $grid_member->nxdomain_redirect_addresses(["10.0.0.10", "10.0.0.20"]); $grid_member->override_nxdomain_redirect("false"); sets override_nxdomain_redirect to "false", and the sequence $grid_member->override_nxdomain_redirect("false"); $grid_member->nxdomain_redirect_addresses(["10.0.0.10", "10.0.0.20"]); sets override_nxdomain_redirect to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_redirect_addresses
my $nxdomain_redirect_addresses = $grid_member->nxdomain_redirect_addresses( );
#Modify nxdomain_redirect_addresses
$grid_member->nxdomain_redirect_addresses(["10.0.0.10", "10.0.0.20"]);
```

nxdomain_redirect_addresses_ipv6( )

Use this method to set the NXDOMAIN redirection IPv6 addresses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of IPv6 addresses. The default value is undefined.

Setting this parameter to a defined value implicitly sets the override_nxdomain_redirect attribute to "true". Setting the parameter to undefined causes the appliance to use the grid-level NXDOMAIN redirection settings and automatically sets the override_nxdomain_redirect attribute to "false" if nxdomain_redirect and nxdomain_redirect_addresses is also undefined. But if nxdomain_redirect or nxdomain_redirect_addresses contains a value, then the override_nxdomain_redirect attribute is set to true.

Note that when nxdomain_redirect_addresses_ipv6 contains a valid array reference and override_nxdomain_redirect is set to "false", the last operation takes precedence. Thus the sequence $grid_member->nxdomain_redirect_addresses_ipv6(["2001:db8::1", "2002:ffff::1"]); $grid_member->override_nxdomain_redirect("false"); sets override_nxdomain_redirect to "false", and the sequence $grid_member->override_nxdomain_redirect("false"); $grid_member->nxdomain_redirect_addresses_ipv6(["2001:db8::1", "2002:ffff::1"]); sets override_nxdomain_redirect to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_redirect_addresses_ipv6
my $nxdomain_redirect_addresses_ipv6 = $grid_member->nxdomain_redirect_addresses_ipv6( );
#Modify nxdomain_redirect_addresses_ipv6
$grid_member->nxdomain_redirect_addresses_ipv6(["2001:db8::1", "2002:ffff::1"]);
```

nxdomain_redirect_ttl( )

Use this method to set or retrieve the TTL value of synthetic DNS responses that result from NXDOMAIN redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the TTL in seconds. The default value is 60.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_redirect_ttl
my $nxdomain_redirect_ttl = $grid_member->nxdomain_redirect_ttl( );
#Modify nxdomain_redirect_ttl
$grid_member->nxdomain_redirect_ttl(60);
```

nxdomain_log_query( )

Use this method to set or retrieve the flag that indicates whether NXDOMAIN redirection queries are logged.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable logging, or "false" to deactivate it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_log_query
my $nxdomain_log_query = $grid_member->nxdomain_log_query( );
#Modify nxdomain_log_query
$grid_member->nxdomain_log_query("true");
```

nxdomain_rulesets( )

Use this method to specify or retrieve Infoblox::DNS::Ruleset object names assigned at the grid level for NXDOMAIN redirection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains the names of the Infoblox::DNS::Ruleset objects assigned to the grid. The names must be in string format. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nxdomain_rulesets
my $nxdomain_rulesets = $grid_member->nxdomain_rulesets();
#Modify nxdomain_rulesets
$grid_member->nxdomain_rulesets(["ruleset1", "ruleset2"]);
```

override_blacklist( )

The "override_blacklist" attribute controls whether the "enable_blacklist", "blacklist_redirect_addresses", "blacklist_redirect_ttl", "blacklist_log_query", and "blacklist_rulesets" values in the database are used.

The "override_blacklist" attribute can be specified explicitly. It is also set implicitly as follows: "enable_blacklist" => "true"|"false" or "blacklist_redirect_addresses" => ["10.0.0.10", "10.0.0.20"]|[] results in "override_blacklist" => "true"; "enable_blacklist" => undef and "blacklist_redirect_addresses" => undef result in "override_blacklist" => "false". If "override_blacklist" is specified explicitly as "true", and "enable_blacklist" => undef or "blacklist_redirect_addresses" => undef, then the explicit value takes precedence. Therefore, "override_blacklist"=>"true", "enable_blacklist"=>undef, and "blacklist_redirect_addresses"=>undef remain unchanged in the database.

Specifying the "blacklist_redirect_ttl", "blacklist_log_query", or "blacklist_rulesets" attributes does not affect the "override_blacklist" value. It is implicitly set only by "enable_blacklist" and "blacklist_redirect_addresses".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level settings of the blacklist redirect attributes. Set the parameter to "false" to inherit the grid-level settings. The default is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_blacklist
my $override_blacklist=$memberdns->override_blacklist( );
#Modify override_blacklist
$memberdns->override_blacklist("true");
```

override_dnssec( )

The "override_dnssec" attribute controls whether the "dnssec_enabled", "dnssec_validation_enabled", "dnssec_expired_signatures_enabled", and "dnssec_trusted_keys" values in the database are used. Note that these values can be overridden at the DNS view level as well.

The "override_dnssec" attribute can be specified explicitly. It is also established implicitly as follows: "dnssec_enabled" => "true"|"false" results in "override_dnssec" => "true" "dnssec_enabled" => undef results in "override_dnssec" => "false" If "override_dnssec" is specified explicitly as "true", while "dnssec_enabled"=>undef, the explicit value takes precedence, and "override_dnssec"=>"true" while "dnssec_enabled" remains unchanged in the database.

Supplying the "dnssec_validation_enabled", "dnssec_expired_signatures_enabled", or "dnssec_trusted_keys" attributes does not affect the "override_dnssec" value. It is implicitly affected only by "dnssec_enabled".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting of DNSSEC attributes. Set the parameter to "false" to inherit the grid-level settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_dnssec
my $override_dnssec=$memberdns->override_dnssec( );
#Modifying override_dnssec
$memberdns->override_dnssec("true");
```

override_dtc_edns_prefer_client_subnet( )

The override_dtc_edns_prefer_client_subnet attribute controls whether the dtc_edns_prefer_client_subnet method values of the member are used, instead of the Grid default.

The override_dtc_edns_prefer_client_subnet attribute can be specified explicitly. It is also set implicitly when dtc_edns_prefer_client_subnet is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for dtc_edns_prefer_client_subnet. Set the parameter to "false" to inherit the Grid-level setting for dtc_edns_prefer_client_subnet. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_dtc_edns_prefer_client_subnet
my $override_dtc_edns_prefer_client_subnet = $memberdns->override_dtc_edns_prefer_client_subnet();
#Modify override_dtc_edns_prefer_client_subnet
$memberdns->override_dtc_edns_prefer_client_subnet("true");
```

override_forwarders( )

The "override_forwarders" attribute controls whether the "forward_only" and "forwarders" values in the database are used.

The "override_forwarders" attribute can be specified explicitly. It is also set implicitly as follows: "forward_only" => "true"|"false" or "forwarders" => ["10.0.0.10", "10.0.0.20"]|[] results in "override_forwarders" => "true"; "forward_only" => undef and "forwarders" => undef result in "override_forwarders" => "false". If "override_forwarders" is specified explicitly as "true", and "forward_only" => undef or "forwarders" => undef, then the explicit value takes precedence. Therefore, "override_forwarders"=>"true", "forward_only"=>undef, and "forwarders"=>undef remain unchanged in the database.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level settings of the forwarders attributes. Set the parameter to "false" to inherit the grid-level settings. The default is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_forwarders
my $override_forwarders=$memberdns->override_forwarders( );
#Modify override_forwarders
$memberdns->override_forwarders("true");
```

override_fixed_rrset_order_fqdns( )

The override_fixed_rrset_order_fqdns controls whether the enable_fixed_rrset_order_fqdns and fixed_rrset_order_fqdns values in the database are used. Note that these values can be overridden at the DNS View level as well.

The override_fixed_rrset_order_fqdns can be specified explicitly. It is also set implicitly as follows: enable_fixed_rrset_order_fqdns => "true" | "false" or fixed_rrset_order_fqdns => $fqdns results in override_fixed_rrset_order_fqdns => "true";

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level fixed RRset order settings. Set the parameter to "false" to inherit the Grid-level settings. The default is "false".

Returns

When you specify a parameter and the modification succeeds, the method returns "true". When the operation fails, the method returns "false".

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get override_fixed_rrset_order_fqdns flag
my $override_fixed_rrset_order_fqdns = $member_dns->override_fixed_rrset_order_fqdns();
#Modify override_fixed_rrset_order_fqdns flag
$member_dns->override_fixed_rrset_order_fqdns("true");
```

query_source_port( )

Use this method to specify the source port for queries. Specifying a source port number for recursive queries ensures that a firewall will allow the response. This setting overrides grid static source port settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Source port number for queries. Valid values are between 1 and 63999. The default is picked by BIND.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting query_source_port
$memberdns->query_source_port( );
#Modifying notify source port
```

```
$memberdns->query_source_port("2");
```

recursive_client_limit( )

Use this method to set a limit on the number of concurrent recursive clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Maximum number of concurrent recursive clients. Range is from 0 to 4294967295

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting recursive_client_limit
$memberdns->recursive_client_limit( );
#Modifying recursive_client_limit
$memberdns->recursive_client_limit("10");
```

recursive_query_list( )

Use this method to set or retrieve the list of IPv4 or IPv6 addresses, networks or hosts authenticated by Transaction signature (TSIG) key from which recursive queries are allowed or denied. This setting overrides grid recursive query list settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4/IPv6 addresses, networks and/or Infoblox::DNS::TSIGKey objects. To deny queries, add '!' as a prefix to IP addresses and networks. Specify "any" to allow any recursive query, or undefine to use the Grid::DNS level recursive_query_list list. Note: You should also undefine the allow_recursive_query list to use Grid::DNS level settings.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting recursive_query_list
$memberdns->recursive_query_list( );
#Modifying recursive_query_list
$memberdns->recursive_query_list(["any"]);

#Creating TSIG key object
my $tsig_key2 = $session->gen_tsig_key();
my $key2 = Infoblox::DNS::TSIGKey->new(
   name => "rcl_key",
   key  => $tsig_key2
);
#Modifying recursive_query_list
$memberdns->recursive_query_list(["10.0.0.10", $key2,
"20.0.0.0/24","2010::256/64","!"."2011::23cb/64","!"."30.0.0.30", "!"."40.10.0.0/24"]);

#Use Grid::DNS level recursive_query_list
$memberdns->recursive_query_list(undef);
$memberdns->allow_recursive_query(undef);

#Use Infoblox::Grid::NamedACL
$memberdns->recursive_query_list($nacl);
```

resolver_query_timeout( )

Use this method to set or retrieve recursive query timeout for the member.

Setting this method to a defined value implicitly sets the override_resolver_query_timeout method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_resolver_query_timeout method to "false".

Note that when resolver_query_timeout is set to a defined value and override_resolver_query_timeout is set to "false", the last operation

takes precedence. Thus the sequence $object->resolver_query_timeout(29); $object->override_resolver_query_timeout("false"); will set override_resolver_query_timeout to "false", and the sequence $object->override_resolver_query_timeout("false"); $object->resolver_query_timeout(29); will result in override_resolver_query_timeout="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer that contains the recursive query time (in seconds) for the resolver.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get resolver_query_timeout
my $resolver_query_timeout = $memberdns->resolver_query_timeout();
#Modify resolver_query_timeout
$memberdns->resolver_query_timeout(29);
```

response_rate_limiting( )

Use this method to set or retrieve response rate limiting settings for the member.

Setting this method to a defined value implicitly sets the override_response_rate_limiting method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_response_rate_limiting method to "false".

Note that when response_rate_limiting is set to a defined value and override_response_rate_limiting is set to "false", the last operation takes precedence. Thus the sequence $object->response_rate_limiting($response_rate_limiting); $object->override_response_rate_limiting("false"); will set override_response_rate_limiting to "false", and the sequence $object->override_response_rate_limiting("false"); $object->response_rate_limiting($response_rate_limiting); will result in override_response_rate_limiting="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::DNS::ResponseRateLimiting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get response_rate_limiting
my $response_rate_limiting = $memberdns->response_rate_limiting();
#Modify response_rate_limiting
$memberdns->response_rate_limiting($response_rate_limiting);
```

recursive_resolver( )

Use this method to set or retrieve the recursive resolver for Member DNS.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is 'BIND' or 'UNBOUND'. The default value is 'BIND'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recursive_resolver
my $recursive_resolver = $memberdns->recursive_resolver();

#Modify recursive_resolver
$memberdns->recursive_resolver('UNBOUND');
```

serial_query_rate( )

Use this method to set or retrieve the number of maximum concurrent SOA queries per second for the Member.

Parameter

Valid values are unsigned integer between 20 and 1000, inclusive. Default value is 20.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $memberdns->serial_query_rate();
# Modify attribute value
$memberdns->serial_query_rate(30);
```

server_id_directive( )

Use this method to set or retrieve the value for the BIND and UNBOUND 'server-id' directive.

Setting this method to a defined value implicitly sets the override_server_id_directive method to "true". Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_server_id_directive method to "false".

Note that when server_id_directive is set to a defined value and override_server_id_directive is set to "false", the last operation takes precedence. Thus the sequence $object->server_id_directive("HOSTNAME"); $object->override_server_id_directive("false"); will set override_server_id_directive to "false", and the sequence $object->override_server_id_directive("false"); $object->server_id_directive("true"); will result in override_server_id_directive="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are "NONE", "HOSTNAME" and "USER_DEFINED". The default value is "NONE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get server_id_directive
my $server_id_directive = $memberdns->server_id_directive();
#Modify server_id_directive
$memberdns->server_id_directive("HOSTNAME");
```

server_id_directive_string( )

Use this method to set or retrieve the value for the BIND and UNBOUND user-defined server ID for 'server-id' directive.

Note that to enable user-defined 'server-id' the server_id_directive should be set to "USER_DEFINED".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired server ID in a string format. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get server_id_directive_string
my $server_id_directive_string = $memberdns->server_id_directive_string();
#Modify server_id_directive_string
$memberdns->server_id_directive_string("test-server-id-1");
```

skip_in_grid_rpz_queries( )

Use this method to set or retrieve the flag that indicates whether the RPZ rules are applied to queries originating from this member received by other members of the Grid or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to allow other members to recieve RPZ queries by other members and 'false' to forbid it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get skip_in_grid_rpz_queries value
my $value = $object->skip_in_grid_rpz_queries();

#Modify skip_in_grid_rpz_queries value
$memberdns->skip_in_grid_rpz_queries('false');
```

sortlist( )

Use this method to create a sort list.

A sort list determines the order of addresses in responses made to DNS queries. This setting overrides grid sort list settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains Infoblox::DNS::Sortlist object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $sort1 = Infoblox::DNS::Sortlist->new (
                        "source_ipv4addr" => "1.2.3.4",
                        "match_list"      => [ "10.20.1.0/24" , "10.20.2.0/24"]
                );
$memberdns_object->sortlist( [ $sort1 ] );
```

store_locally( )

Use this method to set or retrieve the flag that indicates whether the storing of query capture reports on the appliance is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable storing of query capture reports on the appliance or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get store_locally value
my $store_locally = $object->store_locally();

#Modify store_locally value
$object->store_locally('true');
```

transfer_excluded_servers( )

Use this method to exclude specified DNS servers during zone transfers. This setting overrides grid zone transfer settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains IP addresses of the DNS server.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#This means that it will set zone transfer format to Many answers except these servers.
$memberdns->transfer_format("many_answers");
$memberdns->transfer_excluded_servers(["10.0.0.10", "20.0.0.0"]);
```

transfer_format( )

Use this method to set or retrieve the BIND format for a zone transfer. This provides tracking capabilities for single or multiple transfers and their associated servers. This setting overrides grid zone transfer format settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is one of the following values:

`"Many Answers" (Secondaries run BIND 8/9)`: includes as many records as the packet size allows.

`"Many Answers" Except for these servers`: includes as many records as the packet size allows.

`"One Answer" (Secondaries run BIND 4)`: includes one record per packet.

`"One Answer" Except for these servers`: includes one record per packet.

If you specified servers in the transfer_excluded_servers method, the Many Answers or One Answer zone format (depending on transfer_format method setting) will allow zone transfers, except from the specified servers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting transfer_format
$memberdns->transfer_format( );
#Modifying transfer_format
$memberdns->transfer_format("many_answers");
```

transfers_in( )

Use this method to set or retrieve the number of maximum concurrent transfers for the Member.

Parameter

Valid values are unsigned integer between 10 and 100, inclusive. Default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $memberdns->transfers_in();
# Modify attribute value
$memberdns->transfers_in(20);
```

transfers_out( )

Use this method to set or retrieve the number of maximum outbound concurrent zone transfers for the member.

Parameter

Valid values are unsigned integers between 1 and 100, inclusive. The default value is 10.

Specifying value in this parameter sets the override_transfers_out attribute to "true". Setting this parameter attribute to undefined causes a member to use the grid-level transfers_out value and automatically sets the override_transfers_out attribute to "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $memberdns->transfers_out();
# Modify attribute value
$memberdns->transfers_out(20);
```

transfers_per_ns( )

Use this method to set or retrieve the number of maximum concurrent transfers per member for the Member.

Parameter

Valid values are unsigned integer between 2 and 100, inclusive. Default value is 2.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $memberdns->transfers_per_ns();
# Modify attribute value
$memberdns->transfers_per_ns(3);
```

unbound_logging_level( )

Use this method to set or retrieve the logging level for the unbound recursive resolver.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is 'ERRORS_ONLY', 'OPERATIONS', 'DETAILED_OPERATIONS', 'QUERY', 'ALGORITHM' or 'CACHE_MISSES'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get unbound_logging_level
my $unbound_logging_level = $memberdns->unbound_logging_level();

#Modify unbound_logging_level
$memberdns->unbound_logging_level('ALGORITHM');
```

use_lan_ipv6_port( )

Use this method to enable/disable DNS service on the IPv6 LAN port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DNS service on the IPv6 LAN port or "false" to disable it. Default is "false"

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting use_lan_ipv6_port
$memberdns->use_lan_ipv6_port( );
#Modifying use_lan_ipv6_port
$memberdns->use_lan_ipv6_port("true");
```

use_lan2_port( )

Use this method to enable/disable DNS service on the LAN2 port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DNS service on the LAN2 port or "false" to disable it. Default is "false"

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting use_lan2_port
$memberdns->use_lan2_port( );
#Modifying use_lan2_port
$memberdns->use_lan2_port("true");
```

use_lan2_ipv6_port( )

Use this method to enable/disable DNS service on the IPv6 LAN2 port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DNS service on the IPv6 LAN2 port or "false" to disable it. Default is "false"

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting use_lan2_ipv6_port
$memberdns->use_lan2_ipv6_port( );
#Modifying use_lan2_ipv6_port
$memberdns->use_lan2_ipv6_port("true");
```

use_mgmt_port( )

Use this method to enable/disable DNS services on the MGMT port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DNS services on the MGMT port or "false" to disable it. Default is "false"

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting use_mgmt_port
$memberdns->use_mgmt_port( );
#Modifying enable_dns
$memberdns->use_mgmt_port("true");
```

use_mgmt_ipv6_port( )

Use this method to enable/disable DNS services on the IPv6 MGMT port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable DNS services on the IPv6 MGMT port or "false" to disable it. Default is "false"

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting use_mgmt_ipv6_port
$memberdns->use_mgmt_ipv6_port( );
#Modifying enable_dns
$memberdns->use_mgmt_ipv6_port("true");
```

use_root_name_servers( )

Use this method to enable/disable custom or Internet root name servers. This setting overrides the grid root name server settings. Specify "False" to indicate that the member overrides the grid root server setting and uses Internet root name servers. Specify "True" to indicate that the member overrides the grid root server setting and uses custom root name servers. Specify "undef" to indicate that the member does not override the grid root server settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to allow custom root name servers. Specify "false" to use Internet root name servers. Set it to undef to use the grid root name server settings.

Returns

If you specify a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you do not specify a parameter, the method returns the attribute value.

Example

```
#Get use_root_name_servers
my $useRootNS = $memberdns->use_root_name_servers( );
#Modify use_root_name_servers
$memberdns->use_root_name_servers("false");
#Use grid root server settings
$memberdns->use_root_name_servers(undef);
```

rpz_disable_nsdname_nsip( )

Use this method to disable NSDNAME and NSIP resource records from RPZ feeds at member level.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the filter (to filter out NSDNAME and NSIP resource records). Specify "false" to disable the filter. The default value is "false".

Note that if both rpz_disable_nsdname_nsip and override_rpz_disable_nsdname_nsip are set to some value, the last operation takes precedence. Thus the sequence $grid_member->rpz_disable_nsdname_nsip("true"); $grid_member->override_rpz_disable_nsdname_nsip("false"); results in inheriting rpz_disable_nsdname_nsip value from the Grid. And the sequence $grid_member->override_rpz_disable_nsdname_nsip("false"); $grid_member->rpz_disable_nsdname_nsip("true"); sets override_rpz_disable_nsdname_nsip to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting rpz_disable_nsdname_nsip
$my $rpz_filter = $memberdns->rpz_disable_nsdname_nsip( );
#Modifying rpz_disable_nsdname_nsip
$memberdns->rpz_disable_nsdname_nsip("true");
```

rpz_drop_ip_rule_enabled( )

Use this method to set or retreive the flag that indicates whether the DNS server ignores RPZ-IP triggers with large prefix lengths or not.

Setting this method to a defined value implicitly sets the override_rpz_drop_ip_rule method to "true". Setting the parameter to undefined if rpz_drop_ip_rule_min_prefix_length_ipv4 and rpz_drop_ip_rule_min_prefix_length_ipv6 are undefined causes the appliance to use the Grid default and automatically resets the override_rpz_drop_ip_rule attribute to "false".

Note that when rpz_drop_ip_rule_enabled is set to a defined value and override_rpz_drop_ip_rule is set to "false", the last operation takes precedence. Thus the sequence $object->rpz_drop_ip_rule_enabled("true"); $object->override_rpz_drop_ip_rule("false"); will set override_rpz_drop_ip_rule to "false", and the sequence $object->override_rpz_drop_ip_rule("false"); $object->rpz_drop_ip_rule_enabled("true"); will result in override_rpz_drop_ip_rule="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable ignoring of RPZ-IP triggers with large prefix lengths or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $memberdns->rpz_drop_ip_rule_enabled();
# Modify attribute value
$memberdns->rpz_drop_ip_rule_enabled("true");
```

rpz_drop_ip_rule_min_prefix_length_ipv4( )

Use this method to set or retreive minimum prefix length for IPv4 RPZ-IP triggers.

Setting this method to a defined value implicitly sets the override_rpz_drop_ip_rule method to "true". Setting the parameter to undefined if rpz_drop_ip_rule_enabled and rpz_drop_ip_rule_min_prefix_length_ipv6 are undefined causes the appliance to use the Grid default and automatically resets the override_rpz_drop_ip_rule attribute to "false".

Note that when rpz_drop_ip_rule_min_prefix_length_ipv4 is set to a defined value and override_rpz_drop_ip_rule is set to "false", the last operation takes precedence. Thus the sequence $object->rpz_drop_ip_rule_min_prefix_length_ipv4("20"); $object->override_rpz_drop_ip_rule("false"); will set override_rpz_drop_ip_rule to "false", and the sequence $object->override_rpz_drop_ip_rule("false"); $object->rpz_drop_ip_rule_min_prefix_length_ipv4("20"); will result in override_rpz_drop_ip_rule="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 31 that represents prefix length (in bits) for IPv4 RPZ-IP triggers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $member_dns->rpz_drop_ip_rule_min_prefix_length_ipv4();
# Modify attribute value
$member_dns->rpz_drop_ip_rule_min_prefix_length_ipv4("16");
```

rpz_drop_ip_rule_min_prefix_length_ipv6( )

Use this method to set or retreive minimum prefix length for IPv6 RPZ-IP triggers.

Setting this method to a defined value implicitly sets the override_rpz_drop_ip_rule method to "true". Setting the parameter to undefined if rpz_drop_ip_rule_enabled and rpz_drop_ip_rule_min_prefix_length_ipv4 are undefined causes the appliance to use the Grid default and automatically resets the override_rpz_drop_ip_rule attribute to "false".

Note that when rpz_drop_ip_rule_min_prefix_length_ipv6 is set to a defined value and override_rpz_drop_ip_rule is set to "false", the last operation takes precedence. Thus the sequence $object->rpz_drop_ip_rule_min_prefix_length_ipv6("20"); $object->override_rpz_drop_ip_rule("false"); will set override_rpz_drop_ip_rule to "false", and the sequence $object->override_rpz_drop_ip_rule("false"); $object->rpz_drop_ip_rule_min_prefix_length_ipv6("20"); will result in override_rpz_drop_ip_rule="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 127 that represents prefix length (in bits) for IPv6 RPZ-IP triggers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $member_dns->rpz_drop_ip_rule_min_prefix_length_ipv6();
# Modify attribute value
$member_dns->rpz_drop_ip_rule_min_prefix_length_ipv6("120");
```

rpz_qname_wait_recurse( )

Use this method to enable or disable recursive RPZ lookups.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable recursive RPZ lookups or "false" to disable them. The default value is "false".

Note that if both rpz_qname_wait_recurse and override_rpz_qname_wait_recurse are set to some values, the last operation takes precedence. Thus the sequence $grid_member->rpz_qname_wait_recurse("true"); $grid_member->override_rpz_qname_wait_recurse("false"); results in inheriting rpz_qname_wait_recurse value from the Grid. And the sequence $grid_member->override_rpz_qname_wait_recurse("false"); $grid_member->rpz_qname_wait_recurse("true"); sets override_rpz_qname_wait_recurse to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $grid_member->rpz_qname_wait_recurse();
# Modify attribute value
$grid_member->rpz_qname_wait_recurse("true");
```

override_resolver_query_timeout( )

The override_resolver_query_timeout attribute controls whether the resolver_query_timeout method values of the member are used, instead of the Grid default.

The override_resolver_query_timeout attribute can be specified explicitly. It is also set implicitly when resolver_query_timeout is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for resolver_query_timeout. Set the parameter to "false" to inherit the Grid-level setting for resolver_query_timeout.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_resolver_query_timeout
my $override_resolver_query_timeout = $memberdns->override_resolver_query_timeout( );
#Modifying override_resolver_query_timeout
$memberdns->override_resolver_query_timeout("true");
```

override_response_rate_limiting( )

The override_response_rate_limiting attribute controls whether the response_rate_limiting method values of the member are used, instead of the Grid default.

The override_response_rate_limiting attribute can be specified explicitly. It is also set implicitly when response_rate_limiting is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for response_rate_limiting. Set the parameter to "false" to inherit the Grid-level setting for response_rate_limiting.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_response_rate_limiting
my $override_response_rate_limiting = $memberdns->override_response_rate_limiting( );
#Modifying override_response_rate_limiting
$memberdns->override_response_rate_limiting("true");
```

override_rpz_disable_nsdname_nsip( )

The override_rpz_disable_nsdname_nsip attribute controls whether the rpz_disable_nsdname_nsip method value for the member is used, instead of the Grid default.

The "override_rpz_disable_nsdname_nsip" attribute can be specified explicitly. It is also established implicitly as follows: "rpz_disable_nsdname_nsip" => "true"|"false" results in "override_rpz_disable_nsdname_nsip" => "true" "rpz_disable_nsdname_nsip" => undef results in "override_rpz_disable_nsdname_nsip" => "false" If "override_rpz_disable_nsdname_nsip" is specified explicitly as "true", while "rpz_disable_nsdname_nsip"=>undef, the explicit value takes precedence, and "override_rpz_disable_nsdname_nsip"=>"true" while "rpz_disable_nsdname_nsip" remains unchanged in the database.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for rpz_disable_nsdname_nsip. Set the parameter to "false" to inherit the grid-level setting for rpz_disable_nsdname_nsip value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_rpz_disable_nsdname_nsip
my $override_rpz_filter = $memberdns->override_rpz_disable_nsdname_nsip();
#Modyfying override_rpz_disable_nsdname_nsip
$memberdns->override_disable_nsdname_nsip("true");
```

override_rpz_drop_ip_rule( )

The override_rpz_drop_ip_rule attribute controls whether the rpz_drop_ip_rule_enabled, rpz_drop_ip_rule_min_prefix_length_ipv4 and rpz_drop_ip_rule_min_prefix_length_ipv6 method values of the member are used, instead of the Grid default.

The override_rpz_drop_ip_rule attribute can be specified explicitly. It is also set implicitly when one of rpz_drop_ip_rule_enabled, rpz_drop_ip_rule_min_prefix_length_ipv4 or rpz_drop_ip_rule_min_prefix_length_ipv6 methods is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for rpz_drop_ip_rule_enabled, rpz_drop_ip_rule_min_prefix_length_ipv4 and rpz_drop_ip_rule_min_prefix_length_ipv6 methods. Set the parameter to "false" to inherit the Grid-level setting for rpz_drop_ip_rule_enabled, rpz_drop_ip_rule_min_prefix_length_ipv4 and rpz_drop_ip_rule_min_prefix_length_ipv6 methods.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_rpz_drop_ip_rule
my $override_rpz_drop_ip_rule = $memberdns->override_rpz_drop_ip_rule( );
#Modifying override_rpz_drop_ip_rule
$memberdns->override_rpz_drop_ip_rule("true");
```

use_lan_port( )

Use this method to set or retrieve the status of the use of DNS services on the IPv4 LAN1 port.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify true to enable DNS services on the IPv4 LAN1 port of false to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting use_lan_port
my $use_lan_port = $memberdns->use_lan_port();
#Modyfying use_lan_port
$memberdns->use_lan_port("true");
```

views( )

Use this method to specify or retrieve the view of this member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value. The default value is the "default" view, which means the DNS member object is located under the default view.

Parameter

Valid value is an array reference that contains the names of the DNS views associated with the member. The names must be in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get views
my $ref_views = $object->views();
#Modify DNS views, list of DNS view names in string format
$object->views(["view1","view2","view3"]);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object,such as modify and get. This sample also includes error handling for the operations.

#Preparation prior to member DNS object operations

```
#PROGRAM STARTS: Include all the modules that will be used

use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
```

```
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

# Get and modify the member DNS property object. Considering the id grid member named infoblox.localdomain
was previously created.
my $object = $session->get(
    object => "Infoblox::Grid::Member::DNS",
    name   => "infoblox.localdomain"
);

 unless ($object) {
      die("get member DNS failed: ",
      $session->status_code() . ":" . $session->status_detail());
  }
 print "member DNS get  successfull\n";

#Modifying the value of the specified object
$object->enable_dns("true");
$object->forward_only("false");
$object->minimal_resp("true");
$object->use_mgmt_port("true");
$object->notify_source_port(53);
$object->query_source_port(53);

 #Apply the changes
 $session->modify($object)
  or die("modify member DNS failed: ",
      $session->status_code() . ":" . $session->status_detail());

print "DNS member object modified successfully \n";

####PROGRAM ENDS####
```

NAME

Infoblox::Grid::Member::DNS::IP - a Grid member DNS IP.

DESCRIPTION

The DNS IP object is used to configure additional DNS-enabled interfaces for Grid member.

CONSTRUCTOR

```
my $object = Infoblox::Grid::Member::DNS::IP->new(
    member_virtual_ip => $Interface | $ipv4addr | $ipv6addr, #Required
);
```

SESSION METHODS

The object does not have any session methods.

MODULE METHODS

This section describes all the functions that you can apply to DNS IP object.

Infoblox::Grid::Member::DNS->dns_ip_list( )

Use this method to add or retrieve a list of additional IP addresses on which DNS is enabled for a grid member. See Infoblox::Grid::Member::DNS->dns_ip_list() for parameters and return values.

Example

```
#Get dns_ip_list value
my $value = $object->dns_ip_list();

#Modify dns_ip_list

#Construct Infoblox::Grid::Member::DNS::IP object

my $ip = Infoblox::Grid::Member::DNS::IP->new(
    member_virtual_ip => '10.0.0.10',
);

$object->dns_ip_list([$ip]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a DNS IP object.

member_virtual_ip( )

Use this method to set or retrieve the member's additional interface or interface IP address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::Member::Interface object or IPv4 address or IPv6 address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member_virtual_ip value
my $member_virtual_ip = $object->member_virtual_ip();

#Modify member_virtual_ip value
$object->member_virtual_ip('10.0.0.10');
```

NAME

IInfoblox::Grid::Member::DNS::ViewAddressSetting - The Grid member DNS view address settings.

DESCRIPTION

The object provides information about the settings for the query source address and port, zone transfer request address, notify address and port as well as notify delay.

CONSTRUCTOR

```
 my $object = IInfoblox::Grid::Member::DNS::ViewAddressSetting->new(
     enable_notify_source_port        => 'true' | 'false',                          #Optional / Default is
'false'
     enable_query_source_port         => 'true' | 'false',                          #Optional / Default is
'false'
     notify_delay                     => $uint,                                     #Optional / Default is
5
     notify_source_port               => $uint,                                     #Optional / Default is
undefined
     notify_transfer_source_interface => 'VIP' | 'MGMT' | 'LAN2' | 'Any' | $ipaddr, #Optional / Default is
'Any'
     override_notify_delay            => 'true' | 'false',                          #Optional / Default is
'false'
     override_source_port             => 'true' | 'false',                          #Optional / Default is
'false'
     query_source_interface           => 'VIP' | 'MGMT' | 'LAN2' | 'Any' | $ipaddr, #Optional / Default is
'Any'
     query_source_port                => $uint,                                     #Optional / Default is
undefined
     view_name                        => $string,                                   #Required
 );
```

MODULE METHODS

You can apply the following functions to a DNS view address settings object.

Infoblox::Grid::Member::DNS->dns_view_address_settings( )

Use this method to set or retrieve the list of address settings for Grid member views. See Infoblox::Grid::Member::DNS/dns_view_address_settings() for parameters and return values.

Example

```
#Get dns_view_address_settings value
my $value = $object->dns_view_address_settings();

#Construct view address setting
```

```
my $view_address_setting = Infoblox::Grid::Member::DNS::ViewAddressSetting->new('view_name' =>
'view1');

#Modify dns_view_address_settings value
$object->dns_view_address_settings([$view_address_setting]);
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values for a DNS view address settings object.

enable_notify_source_port( )

Use this method to set or retrieve the flag that indicates whether the notify source port setting is enabled.

Setting this method to a defined value implicitly sets the override_source_ports method to 'true'. Setting the parameter to undefined (if enable_query_source_port, query_source_port, notify_source_port are undefined) causes the appliance to use the Grid member default and automatically resets the override_source_ports method to 'false'.

Note that when enable_notify_source_port is set to a defined value and override_source_ports is set to 'false', the last operation takes precedence. Thus the sequence $object->enable_notify_source_port('true'); $object->override_source_ports('false'); will set override_source_ports to 'false', and the sequence $object->override_source_ports('false'); $object->enable_notify_source_port('true'); will result in override_source_ports='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable notify source port setting, and 'false' to disable it.

Returns

When you specify a parameter and the modification succeeds, the method returns 'true'. When the operation fails, the method returns 'false'.

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_notify_source_port value
my $value = $object->enable_notify_source_port();

#Modify enable_notify_source_port value
$object->enable_notify_source_port('true');
```

enable_query_source_port( )

Use this method to set or retrieve the flag that indicates whether the query source port setting is enabled.

Setting this method to a defined value implicitly sets the override_source_ports method to 'true'. Setting the parameter to undefined (if enable_notify_source_port, query_source_port, notify_source_port are undefined) causes the appliance to use the Grid member default and automatically resets the override_source_ports method to 'false'.

Note that when enable_query_source_port is set to a defined value and override_source_ports is set to 'false', the last operation takes precedence. Thus the sequence $object->enable_query_source_port('true'); $object->override_source_ports('false'); will set override_source_ports to 'false', and the sequence $object->override_source_ports('false'); $object->enable_query_source_port('true'); will result in override_source_ports='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable query source port setting, and 'false' to disable it.

Returns

When you specify a parameter and the modification succeeds, the method returns 'true'. When the operation fails, the method returns 'false'.

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_query_source_port value
my $value = $object->enable_query_source_port();

#Modify enable_query_source_port value
$object->enable_query_source_port('true');
```

notify_delay( )

Use this method to set or retrieve the minimum delay (in seconds) between a set of NOTIFY messages.

Setting this method to a defined value implicitly sets the override_notify_delay method to 'true'. Setting the parameter to undefined causes the appliance to use the Grid DNS default and automatically resets the override_notify_delay method to 'false'.

Note that when notify_delay is set to a defined value and override_notify_delay is set to 'false', the last operation takes precedence. Thus the sequence $object->notify_delay('true'); $object->override_notify_delay('false'); will set override_notify_delay to 'false', and the sequence $object->override_notify_delay('false'); $object->notify_delay('true'); will result in override_notify_delay='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 5 and 86400. The default value is 5.

Returns

When you specify a parameter and the modification succeeds, the method returns 'true'. When the operation fails, the method returns 'false'.

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get notify_delay value
my $value = $object->notify_delay();

#Modify notify_delay value
$object->notify_delay(10000);
```

notify_source_port( )

Use this method to set or retrieve the notify source port number.

Setting this method to a defined value implicitly sets the override_source_ports method to 'true'. Setting the parameter to undefined (if enable_query_source_port, enable_notify_source_port, query_source_port are undefined) causes the appliance to use the Grid member default and automatically resets the override_source_ports method to 'false'.

Note that when notify_source_port is set to a defined value and override_source_ports is set to 'false', the last operation takes precedence. Thus the sequence $object->notify_source_port('true'); $object->override_source_ports('false'); will set override_source_ports to 'false', and the sequence $object->override_source_ports('false'); $object->notify_source_port('true'); will result in override_source_ports='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 63999.

Returns

When you specify a parameter and the modification succeeds, the method returns 'true'. When the operation fails, the method returns 'false'.

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get notify_source_port value
my $value = $object->notify_source_port();

#Modify notify_source_port value
$object->notify_source_port(10000);
```

notify_transfer_source_interface( )

Use this method to specify which IP address is used as the source for notify and zone transfer operations.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are 'VIP', 'MGMT', 'LAN2', 'Any' or an IP address. The default is 'VIP'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get notify_transfer_source_interface value
my $value = $object->notify_transfer_source_interface();

#Modify notify_transfer_source_interface value
$object->notify_transfer_source_interface('Any');
```

query_source_interface( )

Use this method to specify which IP address is used as the source for query operations.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are 'VIP', 'MGMT', 'LAN2', 'Any' or an IP address. Default is 'VIP'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get query_source_interface value
my $value = $object->query_source_interface();

#Modify query_source_interface value
$object->query_source_interface('Any');
```

override_notify_delay( )

The override_notify_delay attribute controls whether the notify_delay method values of the member are used, instead of the Grid member default.

The override_notify_delay attribute can be specified explicitly. It is also set implicitly when notify_delay is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to 'true' to override the member-level setting for notify_delay. Set the parameter to 'false' to inherit the member-level setting for notify_delay.

The default value of this parameter is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_notify_delay value
my $value = $object->override_notify_delay();

#Modify override_notify_delay value
$object->override_notify_delay('true');
```

override_source_ports( )

The override_source_ports attribute controls whether the values of enable_notify_source_port, enable_query_source_port, query_source_port and notify_source_port for the member are used, instead of the Grid member default.

The override_source_ports attribute can be specified explicitly. It is also set implicitly when any of enable_notify_source_port, enable_query_source_port, query_source_port, notify_source_port is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to true to override the member-level setting for enable_notify_source_port, enable_query_source_port,

query_source_port, notify_source_port. Set the parameter to 'false' to inherit the member-level setting for source_ports.

The default value of this parameter is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_source_ports value
my $value = $object->override_source_ports();

#Modify override_source_ports value
$object->override_source_ports('true');
```

query_source_port( )

Use this method to set or retrieve the query source port number.

Setting this method to a defined value implicitly sets the override_source_ports method to 'true'. Setting the parameter to undefined (if enable_query_source_port, enable_notify_source_port, notify_source_port are undefined) causes the appliance to use the Grid member default and automatically resets the override_source_ports method to 'false'.

Note that when query_source_port is set to a defined value and override_source_ports is set to 'false', the last operation takes precedence. Thus the sequence $object->query_source_port('true'); $object->override_source_ports('false'); will set override_source_ports to 'false', and the sequence $object->override_source_ports('false'); $object->query_source_port('true'); will result in override_source_ports='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 63999.

Returns

When you specify a parameter and the modification succeeds, the method returns 'true'. When the operation fails, the method returns 'false'.

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get query_source_port value
my $value = $object->query_source_port();

#Modify query_source_port value
$object->query_source_port(10000);
```

view_name( )

Use this method to set or retrieve the DNS view name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired DNS view name in a string format.

Returns

When you specify a parameter and the modification succeeds, the method returns 'true'. When the operation fails, the method returns 'false'.

When you do not specify a parameter, the method returns the attribute value.

Example

```
#Get view_name value
my $value = $object->view_name();

#Modify view_name value
$object->view_name('view1');
```

NAME

Infoblox::Grid::Member::FileDistribution - Grid Member FileDistribution object.

DESCRIPTION

You can configure the file distribution properties of a grid member. You can enable and disable TFTP, HTTP, and FTP services, and set their operational parameters.

CONSTRUCTOR

The Infoblox::Grid::Member::FileDistribution object is automatically generated upon the successful installation of the Infoblox appliance. It does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a grid member FileDistribution object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

Apply the following attributes to get a specific grid member FileDistribution object:

name - Required. Host name in string format

Example

```
my $object   = $session->get(
   object    => "Infoblox::Grid::Member::FileDistribution",
   name      => "infoblox.localdomain",
    );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to take effect. See Infoblox::Session->restart() method.

Example

```
#Use method to modify the enable_tftp Property.
$object->enable_tftp("true");
#Submit modification
my $response = $session->modify( $object );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the file distribution properties of a grid member.

allow_uploads( )

Use this method to enable or disable file uploads for a member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_allow_uploads method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_allow_uploads attribute to "false".

Note that when allow_uploads is set to a defined value and override_dallow_uploads is set to "false", the last operation takes precedence. Thus the sequence $object->allow_uploads("true"); $object->override_allow_uploads("false"); will set override_allow_uploads to "false", and the sequence $object->override_allow_uploads("false"); $object->allow_uploads("true"); will result in override_allow_uploads="true".

Parameter

Specify "true" to enable file uploads or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting allow_uploads
$file_distribution->allow_uploads( );
#Modifying allow_uploads
$file_distribution->allow_uploads("true");
```

name( )

Use this method to retrieve the grid name. This is a required argument.

Parameter

None.

Returns

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $file_distribution->name();
```

enable_tftp( )

Use this method to enable or disable the TFTP service of a member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the TFTP service or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_tftp
$file_distribution->enable_tftp( );
#Modifying enable_tftp
$file_distribution->enable_tftp("true");
```

tftp_port( )

Use this method to specify the port to listen on for the TFTP file distribution service.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Port number for TFTP file distribution service. Valid values are between 1 and 63999. The default is 69.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting tftp_port
$file_distribution->tftp_port( );
#Modifying tftp_port
$file_distribution->tftp_port("1069");
```

tftp_allow_access( )

Use this method to allow TFTP file distribution access from specified IPv4 addresses and networks.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4 addresses and networks. To reject TFTP file distribution access, add '!' as a prefix to IP addresses and networks. Specify "any" to allow any address or set to an empty array to clear the list.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting tftp_allow_access
my $file_distribution = $file_distribution->tftp_allow_access( );
#Modifying tftp_allow_access
$file_distribution->tftp_allow_access(["any"]);
#Modifying tftp_allow_access
$file_distribution->tftp_allow_access(["10.0.0.10", "20.0.0.0/24", "!"."30.0.0.30",
"!"."40.10.0.0/24"]);
#Modifying tftp_allow_access
$file_distribution->tftp_allow_access([]);
#Use Infoblox::Grid::NamedACL
$file_distribution->tftp_allow_access($nacl);
```

enable_http( )

Use this method to enable or disable the HTTP file distribution service of a member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable HTTP file distribution service or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_http
$file_distribution->enable_http( );
#Modifying enable_http
$file_distribution->enable_http("true");
```

enable_http_acl( )

Use this method to enable or disable the ACLs for the HTTP file distribution service of a member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable ACLs for the HTTP file distribution service or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_http_acl
$file_distribution->enable_http_acl( );
#Modifying enable_http_acl
$file_distribution->enable_http_acl("true");
```

http_allow_access( )

Use this method to allow HTTP file distribution access from specified IPv4 addresses and networks. enable_http and enable_http_acl must be set to 'true' in order for this http_allow_access to be usable. Set to an empty array to clear the list.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4 addresses and networks.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting http_allow_access
my $file_distribution = $file_distribution->http_allow_access( );
#Modifying http_allow_access
$file_distribution->http_allow_access(["10.0.0.10", "20.0.0.0/24", "30.0.0.30", "40.10.0.0/24"]);
#Modifying http_allow_access
$file_distribution->http_allow_access([]);
#Use Infoblox::Grid::NamedACL
$file_distribution->http_allow_access($nacl);
```

enable_ftp( )

Use this method to enable or disable the FTP service of a member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the FTP service or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting enable_ftp
$file_distribution->enable_ftp( );
#Modifying enable_ftp
$file_distribution->enable_ftp("true");
```

ftp_port( )

Use this method to specify the port to listen on for the FTP file distribution service.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Port number for the FTP file distribution service. Valid values are between 1 and 63999. The default is 21.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting ftp_port
$file_distribution->ftp_port( );
#Modifying ftp_port
$file_distribution->ftp_port("1022");
```

ftp_allow_access( )

Use this method to allow FTP file distribution access from specified IPv4 addresses and networks.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::NamedACL object or an array reference that contains IPv4 addresses and networks. To reject FTP file distribution access, add '!' as a prefix to IP addresses and networks. Specify "any" to allow any address or set to an empty array to clear the list.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting ftp_allow_access
my $file_distribution = $file_distribution->ftp_allow_access( );
#Modifying ftp_allow_access
$file_distribution->ftp_allow_access(["any"]);
#Modifying ftp_allow_access
$file_distribution->ftp_allow_access(["10.0.0.10", "20.0.0.0/24", "!"."30.0.0.30",
"!"."40.10.0.0/24"]);
#Modifying ftp_allow_access
$file_distribution->ftp_allow_access([]);
#Use Infoblox::Grid::NamedACL
$file_distribution->ftp_allow_access($nacl);
```

ftp_login_banner( )

Use this method to specify the login banner for the FTP file distribution service.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The login banner for the FTP file distribution service. Valid values are strings of up to 256 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting ftp_login_banner
$file_distribution->ftp_login_banner( );
#Modifying ftp_login_banner
$file_distribution->ftp_login_banner("This is my new FTP login banner");
```

ftp_enable_passive_mode( )

Use this method to enable or disable the FTP service in passive mode.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the FTP service in passive mode or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting ftp_enable_passive_mode
$file_distribution->ftp_enable_passive_mode( );
#Modifying ftp_enable_passive_mode
$file_distribution->ftp_enable_passive_mode("true");
```

ftp_enable_file_listing( )

Use this method to enable or disable file listing for the FTP service.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable file listing or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting ftp_enable_file_listing
$file_distribution->ftp_enable_file_listing( );
#Modifying ftp_enable_file_listing
$file_distribution->ftp_enable_file_listing("true");
```

override_allow_uploads( )

The override_allow_uploads attribute controls whether the allow_uploads value in the member is used, instead of the grid default.

The override_allow_uploads attribute can be specified explicitly. It is also set implicitly when allow_uploads is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_allow_uploads flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_allow_uploads for the member
my $type = $file_distribution->override_allow_uploads();
#Modify override_allow_uploads for the member
$file_distribution->override_allow_uploads("true");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as modify and get. This sample also includes error handling for the operations.

#Preparation prior to member FileDistribution object operations

```
#PROGRAM STARTS: Include all the modules that will be used
```

```
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Get and modify a Member FileDistribution object

```
# Get and modify the member FileDistribution property object. Note that the grid member named
infoblox.localdomain was previously created.
my $object = $session->get(
    object => "Infoblox::Grid::Member::FileDistribution",
    name   => "infoblox.localdomain"
);

 unless ($object) {
      die("get member FileDistribution failed: ",
      $session->status_code() . ":" . $session->status_detail());
  }
 print "member FileDistribution get successful\n";

#Modifying the value of the specified object
$object->enable_tftp("true");
$object->tftp_allow_access(["any"]);
$object->enable_http("true");
$object->enable_http_acl("true");
$object->http_allow_access(["10.0.0.10", "20.0.0.0/24"]);
$object->enable_ftp("true");
$object->ftp_allow_access(["10.0.0.10", "20.0.0.0/24", "!"."30.0.0.30", "!"."40.10.0.0/24"]);
$object->tftp_port(1069);
$object->ftp_port(1022);
$object->ftp_login_banner("My new banner");
$object->ftp_enable_passive_mode("true");

 #Apply the changes
 $session->modify($object)
  or die("modify member FileDistribution failed: ",
      $session->status_code() . ":" . $session->status_detail());

print "FileDistribution member object modified successfully \n";

NAME

Infoblox::Grid::Member::Interface - Interface member object.

DESCRIPTION

An Interface member object represents additional interface information that can be used at the member level. A single IPv6 address may be added to each member by using an Interface object.

CONSTRUCTOR

```
my  $interface = Infoblox::Grid::Member::Interface->new(
    anycast     => "true" | "false",                          #Optional / Default is "false"
    cidr        => $prefix,                                   #Optional / Default is undefined
    comment     => $string,                                   #Optional / Default is undefined
    enable_bgp  => "true" | "false",                          #Optional / Default is "false"
    enable_ospf => "true" | "false",                          #Optional / Default is "false"
    enable_ipv6_auto_config => "true" | "false",              #Optional / Default is "false"
    gateway     => $ipv4addr | $ipv6addr,                     #Optional / Default is undefined
    interface   => "LAN_HA" | "LOOPBACK" | "MGMT" | "LAN2",   #Optional / Default is "LOOPBACK"
    ipv4addr    => $ipv4addr,                                 #Optional / Default is undefined
    ipv6addr    => $ipv6addr,                                 #Optional / Default is undefined
    subnet_mask => $netmask                                   #Optional / Default is undefined
    dscp          => $uint,                                   #Optional / Default is undefined
    override_dscp => "true" | "false",                        #Optional / Default is "false"
    vlan_id       => $uint,                                   #Optional / Default is undefined
);
```

MODULE METHODS

The following functions are available to be applied to an Interface object.

Infoblox::Grid::Member->additional_ip_list( )

Use this function to specify Interface for the Grid Member. See Infoblox::Grid::Member->additional_ip_list() for parameters and return values.

Example 1

```
#Construct an Interface object
my $interface1 = Infoblox::Grid::Member::Interface->new(
```

```
    ipv4addr    => "10.2.3.4",
    anycast     => "true",
    interface   => "LOOPBACK",
    subnet_mask => "255.255.255.255",
    comment     => "this is a loopback interface"
);

# Configure Interface on the Grid Member object
my $response = $Grid_Member->additional_ip_list([$interface1]);
```

Example 2

```
#Construct an IPv6 Interface object for member addition
my $interface6 = Infoblox::Grid::Member::Interface->new(
    ipv6addr    => "2001::1234",
    gateway     => "2001::1111",
    anycast     => "false",
    interface   => "LAN_HA",
    cidr        => "64",
    comment     => "this is an IPv6 address"
);

# Configure Interface on the Grid Member object
my $response = $Grid_Member->additional_ip_list([$interface6]);
```

Example 3

```
#Construct an IPv6 Interface object for member addition with IPv6 auto-configuration turned on
my $interface6 = Infoblox::Grid::Member::Interface->new(
    ipv6addr    => "2001::1234",
    enable_ipv6_auto_config  => "true",
    anycast     => "false",
    interface   => "LAN_HA",
    cidr        => "64",
    comment     => "this is an IPv6 address with auto-configuration turned on"
);

# Configure Interface on the Grid Member object
my $response = $Grid_Member->additional_ip_list([$interface6]);
```

Infoblox::Grid::Member::DNS->additional_ip_list( )

Use this function to specify Interface for the Grid Member DNS. See Infoblox::Grid::Member::DNS->additional_ip_list() for parameters and return values.

Example

```
#Construct an Interface object
my $interface2 = Infoblox::Grid::Member::Interface->new(
    ipv4addr    => "11.22.33.44",
    anycast     => "true",
    interface   => "LOOPBACK",
    subnet_mask => "255.0.0.0",
    comment     => "this is a loopback interface"
);

# Configure Interface on the Grid Member DNS object
my $response = $Grid_Member_DNS->additional_ip_list([$interface2]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Interface object.

anycast( )

Use this method to enable/disable anycast of the Interface object.

When anycast is enabled the Interface is served for anycast usage.

Parameter

Specify "true" to enable anycast or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get anycast
my $anycast = $interface->anycast();
#Modify anycast
$interface->anycast("false");
```

cidr( )

Use this method to set or retrieve the CIDR netmask format of the Inteface object. Required only when ipv6addr is specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the netmask in CIDR format (example: "8" should be specified for netmask 255.0.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get cidr
my $cidr = $interface->cidr();
#Modify cidr
$interface->cidr("16");
```

comment( )

Use this method to set or retrieve a descriptive comment of Interface object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 512 bytes. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $interface->comment();
#Modify comment
$interface->comment("Modifying the Interface comment");
```

dscp( )

Use this method to set or retrieve the DSCP value of the Interface object.

Setting this method to a defined value implicitly sets the override_dscp method to "true". Setting the parameter to undefined causes the appliance to use the member default and automatically resets the override_dscp attribute to "false".

Note that when dscp is set to a defined value and override_dscp is set to "false", the last operation takes precedence. Thus the sequence $object->dscp(11); $object->override_dscp("false"); will set override_dscp to "false", and the sequence $object->override_dscp("false"); $object->dscp(11); will result in override_dscp="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are integers between 0 and 63, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
```

```
my $value = $interface->dscp();
#Modify attribute value
$interface->dscp(11);
```

enable_bgp( )

Use this method to set or retrieve the BGP advertisement setting for this interface.

Parameter

Specify "true" to enable BGP advertisements on this interface or "false" to disable them. Enabling advertisements requires the anycast attribute to be set to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get enable_bgp
my $enable_bgp = $interface->enable_bgp();
#Modify enable_bgp
$interface->enable_bgp("true");
```

enable_ospf( )

Use this method to set or retrieve the OSPF advertisement setting for this interface.

Parameter

Specify "true" to enable OSPF advertisement on this interface or "false" to disable it. Enabling advertisement requires the anycast attribute to be set to "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get enable_ospf
my $enable_ospf = $interface->enable_ospf();
#Modify enable_ospf
$interface->enable_ospf("true");
```

enable_ipv6_auto_config( )

Use this method to enable/disable IPv6 auto-configuration of the Interface object.

When IPv6 auto-configuration is enabled, a gateway is not needed since it will be automatically discovered.

Parameter

Specify "true" to enable IPv6 auto-configuration or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get IPv6 auto-configuration
my $ipv6_autoconfig_enabled = $interface->enable_ipv6_auto_config();
#Modify IPv6 auto-configuration
$interface->enable_ipv6_auto_config("true");
```

gateway( )

Use this method to set or retrieve the gateway of the Interface object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the gateway of the Interface in IPv4 address format or IPV6 address format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2). An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 12ab:0000:0000:0123:4567:89ab:0000:cdef).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get gateway
my $gateway = $interface->gateway();
#Modify gateway
$interface->gateway("10.1.1.1");
```

interface( )

Use this method to set or retrieve the interface type of this Interface object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the interface type in string format. Valid values are "LOOPBACK", "LAN_HA", "MGMT" or "LAN2". Default value is "LOOPBACK".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interface
my $interface = $interface->interface();
#Modify interface
$interface->interface("LAN2");
```

ipv4addr( )

Use this method to set or retrieve the IPV4 address used for the Interface object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $interface->ipv4addr();
#Modify ipv4addr
$interface->ipv4addr("2.2.2.2");
```

ipv6addr( )

Use this method to set or retrieve the IPV6 address used for the Interface object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 12ab:0000:0000:0123:4567:89ab:0000:cdef). IPv6 gateway, and an CIDR are used in conjunctions with ipv6addr ( ).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6addr
my $ipv6addr = $interface->ipv6addr();
#Modify ipv6addr
$interface->ipv6addr("aaaa:1111:bbbb:2222:cccc:3333:dddd:5555");
```

subnet_mask( )

Use this method to set or retrieve the subnet mask of the Interface object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the subnet mask of the Interface in IPv4 address format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 255.0.0.0).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subnet_mask
my $ipv4_subnet_mask = $interface->subnet_mask();
#Modify subnet_mask
$interface->subnet_mask("255.255.255.255");
```

override_dscp( )

The override_dscp attribute contols whether the DSCP value is used, instead of the Member default.

The override_dscp attribute can be specified explicitly. It is also set implicitly when DSCP is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_dscp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_dscp from the member
my $override = $interface->override_dscp();
#Modify override_dscp
$interface->override_dscp("true");
```

vlan_id( )

Use this method to set or retrieve the VLAN ID of the Interface object.

Parameter

Valid values are unsigned integers between 1 and 4095, inclusive. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $attr = $interface->vlan_id();
#Modify attribute value
$interface->vlan_id(10);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an Interface object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to Interface object insertion

```
use strict;
use warnings;
use Infoblox;

my $host_name = "infoblox.localdomain";
my $host_ip   = "192.168.1.2";
#Creating a session to Infoblox appliance.
my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);

unless ($session) {
    die(qq(constructor for session failed: ),
        join(":", Infoblox::status_code(), Infoblox::status_detail()));
}
print "Session created successfully \n";
```

#Create an Interface object

```
#Creating Interface object.
my $interface1 = Infoblox::Grid::Member::Interface->new(
    ipv4addr     => "10.2.3.4",
    anycast      => "false",
    interface    => "LOOPBACK",
    subnet_mask  => "255.255.255.255",
   ) or die(qq(Constructor for interface1 failed: ),
   join(":", Infoblox::status_code(), Infoblox::status_detail()));
print "Interface object constructed successfully \n";
```

#Add Interface object to Grid Member

```
#Getting the member object from appliance through session.
my @result = $session->get(
    object => "Infoblox::Grid::Member",
    name   => $host_name,
    ) or die(qq(Get Grid Member failed: ),
    join(":", $session->status_code(), $session->status_detail()));
print "Get Grid Member successful\n";

my $result = $result[0];
if ($result) {
    #Modifying the value of the Interface method from the member object.
    $result->additional_ip_list([$interface1]);
    #Applying the changes to appliance through session.
    $session->modify($result)
        or die(qq(Modify Grid Member failed: ),
        join(":", $session->status_code(), $session->status_detail()));
}
print "Interface object added to Grid Member successfully\n";
```

#Modify Interface object

```
#Modifying the comment of the Interface object.
$interface1->comment("Modified Comment");

#Apply changes to the Grid Member object.
$result->additional_ip_list([$interface1]);

#Update Grid Member object through the Infoblox session.
$session->modify($result)
  or die("Modify Grid Member object failed: ",
  $session->status_code() . ":" . $session->status_detail());
print "Grid Member object with modified Interface updated to Infoblox appliance successfully\n";
```

#Remove Interface object

```
#Remove the Interface from the Grid Member object.
$result->additional_ip_list([]);

#Update Grid Member object through the Infoblox session.
```

```
$session->modify($result)
  or die("Modify Grid Member object failed: ",
  $session->status_code() . ":" . $session->status_detail());
print "Removed Interface object from Grid Member successfully\n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::Member::IPv6StaticRoute - Static route member object

DESCRIPTION

An IPv6StaticRoute object provides IPv6 static route information for a grid member.

CONSTRUCTOR

```
my $route = Infoblox::Grid::Member::IPv6StaticRoute->new(
        "address" => $ip_address,        #Required
        "gateway" => $ip_address,        #Required
        "cidr"    => $cidr,                      #Required
);
```

MODULE METHODS

The following functions can be applied to an IPv6staticroute object.

Infoblox::Grid::Member->ipv6_static_routes( )

Use this function to specify an IPv6staticroute object for the grid member. See Infoblox::Grid::Member->ipv6_static_routes() for parameters and return values.

Example

```
#Get static routes list
my $ipv6_static_routes = $grid_member->ipv6_static_routes();
#Modify static routes list
my $route = Infoblox::Grid::Member::IPv6StaticRoute->new(
        "address" => "2002::5",
        "cidr"    => 64
        "gateway" => "2002::1",
);
$grid_member->ipv6_static_routes([$route]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an IPv6 static route object.

address( )

Use this method to set or retrieve the IPv6 address of an IPv6 static route object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the address
my $address= $route->address();
#Modify the address
$route->address("2002::5");
```

cidr( )

Use this method to set or retrieve the cidr of the IPv6 static route object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the netmask in CIDR format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the cidr
my $cidr= $route->cidr();
#Modify the cidr
$route->cidr(64);
```

gateway( )

Use this method to set or retrieve the gateway of the IPv6 static route object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the gateway address
my $gateway= $route->gateway();
#Modify the gateway address
$route->gateway("2002::1");
```

NAME

Infoblox::Grid::Member::License - License object.

DESCRIPTION

Licenses are pre-installed on an Infoblox device according to the software packages ordered at the time of purchase. You can upgrade an Infoblox device with the Keystone license. Contact Infoblox Technical Support to get the Keystone license and install it on the device.

CONSTRUCTOR

```
my $license = Infoblox::Grid::Member::License->new(
    key  => $string,    #Required
);
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a License object.

Infoblox::Session->add( )

Use this method to add a License object to the Infoblox device. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $license = Infoblox::Grid::Member::License->new(
    key  => "EQAAAIMhrdkGjSnnmBlgQSA14b16"
);

# Submit for addition
my $response = $session->add( $license );
```

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attributes to search the License object(s):

    "type"  - Optional. The license type.
    "limit" - Optional. The limitation of license.
    "key"   - Optional. The license string.
```

Example

```
my $retrieved_objs = $session->get(object => "Infoblox::Grid::Member::License");
```

Infoblox::Session->search( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attributes to search the License object(s):

    "type"  - Optional. The license type.
    "limit" - Optional. The limitation of license.
    "key"   - Optional. The license string.
```

Example

```
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::Member::License",
    type   => "DNS"
);
```

Infoblox::Session->remove( )

Use this method to remove a License object from the Infoblox device. See Infoblox::Session->remove() for parameters and return values.

Example

```
# Remove the object
my $response = $session->remove( $license );
```

Infoblox::Grid::Member->node1_licenses( ) / Infoblox::Grid::Member->node2_licenses( )

Use this function to retrieve the licenses of a specific Infoblox grid member.

Example

```
#Retrieve the licenses from a grid member
my $licenses = $grid_member->node1_licenses();
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of a License object.

expiration( )

Use this method to retrieve the license expiration timestamp. This is a read-only attribute.

Parameter

None

Returns

The method returns the number of seconds elapsed since January 1, 1970, in UTC format.

Example

```
#Get expiration value
my $expiration = $object->expiration();
```

expiration_status( )

Use this method to retrieve the license expiration status. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get expiration_status value
my $expiration_status = $object->expiration_status();
```

key( )

Use this method to set or retrieve the license key.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the string with the license key of the device.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get key
my $key = $license->key();

#Modify key
$license->key("EQAAAKsmItQcEWiFb6csgab2VeQ7");
```

kind( )

Use this method to retrieve the overall type of license. This is a read-only attribute.

Parameter

None.

Returns

The method returns the attribute value. Valid values are:

```
"Static"  - The overall license type is static license.

"Dynamic" - The overall license type is dynamic license.
```

Example

```
#Get the overall type of license
my $kind = $license->kind();
```

hwid( )

Use this method to retrieve the hardware ID of the physical node on which the license is installed. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get the hardware ID
my $hwid = $license->hwid();
```

limit( )

Use this method to retrieve the license limit value. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get limit value
my $limit = $object->limit();
```

limit_context( )

Use this method to retrieve the context of the license limit. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get limit_context value
my $limit_context = $object->limit_context();
```

type( )

Use this method to retrieve the type of license.

Returns

The method returns the attribute value. Valid values are:

```
"AnyCast"                   - Enables the AnyCast services.

"Cloud Network Automation"  - Enable cloud functionality for the GUI.

"Cloud Platform"            - Enable cloud API service on the Cloud Platform Appliance.

"DNSCacheAcceleration"      - Enables the DNS Cache Acceleration service.

"DDI Trial"                 - Enables the DDI Trial mode.

"DHCP"                      - Enables the Dynamic Host Configuration Protocol (DHCP) service.

"Discovery"                 - Enables the Discovery service.

"DNS"                       - Enables the Domain Name System (DNS) service.

"DNS Query Rewrite"         - Enables support for DNS Query Rewrite.

"FireEye"                   - Enables support for FireEye zones.

"KeystoneDVS"               - Enables Grid-based global management and reporting for Domain Name
System (DNS), Dynamic Host Configuration Protocol (DHCP), and IP address management (IPAM) appliance
solutions.

"KeystoneSup"               - Enables the Grid maintenance service.

"IF-MAP Service"            - Enables the IF-MAP service.

"IF-MAP Federation"         - Enables support for IF-MAP Federation connectors.

"IF-MAP Evaluation"         - Enables support for IF-MAP Evaluation.

"IPAM Freeware"             - Enables IPAM Express.

"LDAP"                      - Enables the Lightweight Directory Access Protocol (LDAP) service.

"Load Balancer"             - Enables support for Load Balancer.

"Multi-Grid Management"     - Enables Multi-Grid Management.

"MS Management"             - Enables Microsoft Management.

"NIOSMaintenance"           - Enables nonstop core network services such as Domain Name System
(DNS), Dynamic Host Configuration Protocol (DHCP), and IP address management (IPAM).

"OEM"                       - Enables OEM mode.

"Query Redirection"         - Enables the Query Redirection service.

"RADIUS"                    - Enables the RADIUS service.

"Reporting"                 - Enables the Reporting service.

"Response Policy Zones"     - Enables support for Response Policy zones.

"Security Ecosystem"        - Enables support for Security Ecosystem services, such as the TAXII
```

```
server.

 "Trinzic Automation Engine" - Enables the Network Automation Engine.

 "Threat Protection"         - Enables the Threat Protection service.

 "Threat Protection Update"  - Enables the Threat Protection Update service.

 "Threat Protection Software Add-On" - Enables the Threat Protection Software Add-On.

 "vNIOS"                     - Enables support for a specific vNIOS virtual appliance model.

 "Threat Analytics"          - Enables the Threat Analytics service.

 "Security Ecosystem"        - Enables the Security Ecosystem feature.

 "Flex Grid Activation"      - Allows all features to be enabled unless there is a conflict with
hardware or existing enabled services.
```

Example

```
 #Get type
 my $type = $license->type();
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to a License object, such as create and remove an object. This sample code also includes error handling for the operations.

#Preparation prior to a license insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox device
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);

unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Add License object to Infoblox device

```
#Construct a License object

my $license = Infoblox::Grid::Member::License->new(
    key  => "EQAAAIMhrdkGjSnnmBlgQSA14b16"
);

unless ($license) {
   die("Construct License object failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "License object created successfully\n";

#Adding the license object to Infoblox Appliance through session.
$session->add($license)
    or die("Add License failed: ",
           $session->status_code() . ":" . $session->status_detail() . "\nPlease contact Infoblox
Technical Support to get the license key and add them to the device\n");

print "Added License to Infoblox Appliance successfully.\n";

####PROGRAM ENDS####
```

NAME

Infoblox::Grid::Member::OSPF - OSPF (Open Shortest Path First) member object.

DESCRIPTION

A OSPF member represents the configuration for a OSPF area used at the grid member level.

CONSTRUCTOR

```
my  $ospf = Infoblox::Grid::Member::OSPF->new(
    area_id             => $num | $ipv4addr,                        #Required
    interface           => "LAN_HA" | $ipaddr                       #Required
    area_type           => "standard" | "stub" | "nssa",            #Optional / Default is "standard"
    authentication_key  => $string | undef,                         #Optional / Default is undefined
    authentication_type => "none" | "simple" | "message-digest",    #Optional / Default is "none"
    bfd_template        => $string | undef,                         #Optional / Default is undefined
    enable_bfd          => "true" | "false"                         #Optional / Default is "false"
    comment             => $string | undef,                         #Optional / Default is undefined
    cost                => $num | "AUTO",                           #Optional / Default is "AUTO"
    dead_interval       => $num,                                    #Optional / Default is 40
    hello_interval      => $num,                                    #Optional / Default is 10
    key_id              => $num | undef,                            #Optional / Default is 1
    retransmit_interval => $num,                                    #Optional / Default is 5
    transmit_delay      => $num                                     #Optional / Default is 1
    is_ipv4             => "true" | "false"                         #Optional / Default is "true"
);
```

MODULE METHODS

The following functions are available to be applied to a OSPF object.

Infoblox::Grid::Member->ospf_list( )

Use this function to specify OSPF for the Grid Member. See Infoblox::Grid::Member->ospf_list() for parameters and return values.

Example

```
#Construct a OSPF object
my $ospf = Infoblox::Grid::Member::OSPF->new(
    area_id             => "20",
```

```
    area_type           => "standard",
    interface           => "LAN_HA",
    authentication_type => "simple",
    authentication_key  => "infoblox"
);

# Configure OSPF on the Grid Member object
my $response = $Grid_Member->ospf_list([$ospf]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a OSPF object.

area_id( )

Use this method to set or retrieve the area id value of the OSPF object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the area id in a 32-bit integer (range from 0 to 4294967295) format or in IPv4 address format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get area_id
my $area_id = $ospf->area_id();
#Modify area_id
$ospf->area_id(1);
```

area_type( )

Use this method to set or retrieve the OSPF area type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the area type in string format. Valid values are "standard", "stub" OR "nssa"(Not-so-stubby). Default value is "standard".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get area_type
my $area_type = $ospf->area_type();
#Modify area_type
$ospf->area_type("stub");
```

authentication_key( )

Use this method to set the authentication password to use for OSPF. This is a write-only attribute. The authentication key is valid only when authentication type is "simple" or "message-digest".

Include the specified parameter to set the attribute value.

Parameter

Specify the authentication key in string format. The authentication key can have a maximum of 8 bytes if authentication type is "simple" or it can have a maximum of 16 bytes if the authentication type is "message-digest". Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify authentication_key
$ospf->authentication_key("infoblox");
```

authentication_type( )

Use this method to set or retrieve the authentication type used for the OSPF advertisement.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the authentication type in string format. Valid values are "none", "simple" or "message-digest". Default value is "none".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get authentication_type
my $authentication_type = $ospf->authentication_type();
#Modify authentication_type
$ospf->authentication_type("message-digest");
```

bfd_template( )

Use this method to set or retrieve the Bidirectional Forwarding Detection (BFD) template name.

BFD template is used to configure advanced BFD settings such as timer intervals, authentication.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired BFD template in string format. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bfd_template value
my $bfd_template = $object->bfd_template();
#Modify bfd_template value
$object->bfd_template("template1");
```

comment( )

Use this method to set or retrieve a descriptive comment of the OSPF configuration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes. Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $ospf->comment();
#Modify comment
$ospf->comment("Modifying the OSPF comment");
```

cost( )

Use this method to set or retrieve the cost metric associated with the OSPF advertisement. If "AUTO" is provided, cost metric will be generated automatically.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the cost metric in a 16-bit integer (range from 0 to 65535) format or in string format as "AUTO". Default value is "AUTO".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get cost
my $cost = $ospf->cost();
#Modify cost
$ospf->cost(1);
```

dead_interval( )

Use this method to set or retrieve the dead interval value of OSPF. The dead interval describes the time taken in seconds to wait before declaring that the device is unavailable and down.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the dead interval in a 16-bit integer (range from 0 to 65535) format that represents the duration in seconds. Default value is 40.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dead_interval
my $dead_interval = $ospf->dead_interval();
#Modify dead_interval
$ospf->dead_interval(10);
```

enable_bfd( )

Use this method to set or retrieve the flag that indicates whether the Bidirectional Forwarding Detection (BFD) fallover is enabled or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable BFD fallover and false to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_bfd value
my $enable_bfd = $object->enable_bfd();
#Modify enable_bfd value
$object->enable_bfd('true');
```

hello_interval( )

Use this method to set or retrieve the hello interval value of OSPF. The hello interval specifies how often to send OSPF hello advertisement, in seconds.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the hello interval in a 16-bit integer (range from 0 to 65535) format that represents the duration in seconds. Default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get hello_interval
my $hello_interval = $ospf->hello_interval();
#Modify hello_interval
$ospf->hello_interval(20);
```

interface( )

Use this method to set or retrieve the interface that send out OSPF advertisement information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is "LAN_HA" or an IPv4 or IPv6 address of the VLAN interface.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interface
my $interface = $ospf->interface();
#Modify interface
$ospf->interface("LAN_HA");
```

is_ipv4( )

Use this method to set or retrieve the OSPF protocol version.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" if the IPv4 version of OSPF is used, or "false" if the IPv6 version of OSPF is used. Default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get protocol version
my $ospf_is_ipv4 = $ospf->is_ipv4();
#Modify protocol version
$ospf->is_ipv4("true");
$ospf->is_ipv4("false");
```

key_id( )

Use this method to set or retrieve the hash key identifier to use for "message-digest" authentication. The hash key identifier is valid only when authentication type is "message-digest".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the hash key identifier in a 8-bit integer (range from 0 to 255) format. Default value is 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get key_id
my $key_id = $ospf->key_id();
#Modify key_id
$ospf->key_id(100);
```

retransmit_interval( )

Use this method to set or retrieve the retransmit interval time of OSPF. The retransmit interval describes the time taken in seconds to wait before retransmitting OSPF advertisement.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the retransmit interval in a 16-bit integer (range from 0 to 65535) format that represents the duration in seconds. Default value is 5.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get retransmit_interval
my $retransmit_interval = $ospf->retransmit_interval();
#Modify retransmit_interval
$ospf->retransmit_interval(50);
```

transmit_delay( )

Use this method to set or retrieve the transmit delay value of OSPF. The transmit delay describes the time taken in seconds to wait before sending an advertisement.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the transmit delay in a 16-bit integer (range from 0 to 65535) format that represents the duration in seconds. Default value is 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get transmit_delay
my $transmit_delay = $ospf->transmit_delay();
#Modify transmit_delay
$ospf->transmit_delay(60);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an OSPF object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to OSPF object insertion

```
use strict;
use warnings;
use Infoblox;

my $host_name = "infoblox.localdomain";
my $host_ip = "192.168.1.2";
#Creating a session to Infoblox appliance.
my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
```

```
unless ($session) {
    die(qq(constructor for session failed: ),
        join(":", Infoblox::status_code(), Infoblox::status_detail()));
}
print "Session created successfully \n";
```

#Create a grid member OSPF object

```
#Creating OSPF object.
my $ospf1 = Infoblox::Grid::Member::OSPF->new(
    area_id             => "20",
    area_type           => "standard",
    interface           => "LAN_HA",
    authentication_type => "simple",
    authentication_key  => "infoblox"
   ) or die(qq(Constructor for ospf1 failed: ),
   join(":", Infoblox::status_code(), Infoblox::status_detail()));
print "OSPF object constructed successfully \n";
```

#Add OSPF object to Grid Member

```
#Getting the member object from appliance through session.
my @result = $session->get(
    object => "Infoblox::Grid::Member",
    name   => $host_name,
    ) or die(qq(Get Grid Member failed: ),
    join(":", $session->status_code(), $session->status_detail()));
print "Get Grid Member successful\n";

my $result = $result[0];
if ($result) {
    #Modifying the value of the ospf method from the member object.
    $result->ospf_list([$ospf1]);
    #Applying the changes to appliance through session.
    $session->modify($result)
        or die(qq(Modify Grid Member failed: ),
        join(":", $session->status_code(), $session->status_detail()));
}
print "OSPF object added to Grid Member successfully\n";
```

#Modify OSPF object

```
#Modifying the area id of the OSPF object.
$ospf1->area_id("50");

#Apply changes to the Grid Member object.
$result->ospf_list([$ospf1]);

#Update Grid Member object through the Infoblox session.
$session->modify($result)
  or die("Modify Grid Member object failed: ",
  $session->status_code() . ":" . $session->status_detail());
print "Grid Member object with modified OSPF updated to Infoblox appliance successfully\n";
```

#Remove OSPF object

```
#Remove the OSPF from the Grid Member object.
$result->ospf_list([]);

#Update Grid Member object through the Infoblox session.
$session->modify($result)
  or die("Modify Grid Member object failed: ",
  $session->status_code() . ":" . $session->status_detail());
print "Removed OSPF object from Grid Member successfully\n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::Member::ParentalControl - A Parental Control member object.

DESCRIPTION

The Parental Control member object - provides information and configuration for member Parental Control feature.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a Parental Control member object.

Note that Parental Control member is automatically created when Infoblox::Grid::Member object is created and cannot be created and/or removed.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

Apply the following attributes to get a specific Parental Control member object:

```
name - Optional. The Parental Control member host name.
```

Example

```
#Get member with name 'collector1.com'
my $object = $session->get(
    object => 'Infoblox::Grid::Member::ParentalControl',
    name   => 'collector1.com',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify enable_service value
$object->enable_service('true');

#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

Apply the following attributes to get a specific Parental Control member object:

```
name - Optional. The Parental Control member host name.
```

Example

```
#Get member with name 'collector1.com'
my $object = $session->get(
    object => 'Infoblox::Grid::Member::ParentalControl',
    name   => 'collector1.com',
);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a Parental Control member object.

enable_service( )

Use this method to set or retrieve the flag that indicates whether the Parental Control service is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the Parental Control service or 'false' to disable/deactivate it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_service value
my $enable_service = $object->enable_service();

#Modify enable_service value
$object->enable_service('true');
```

name( )

Use this method to retrieve the Parental Control member host name. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();
```

NAME

Infoblox::Grid::Member::PNodeToken - Physical Node Token object.

DESCRIPTION

This object is used as a permission token for a pre-provisioned member to automatically join the Grid.

CONSTRUCTOR

This object actually have no constructor, it is only returned by create_token and read_token function calls of Infoblox::Grid::Member class.

METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a License object.

Infoblox::Grid::Member->physical_oid( )

Use this method to retrieve the OID of the physical node for which the token is created.

Parameter

None

Returns

The method returns the attribute value, which is an integer number.

Example

```
# get the physical_oid value for the token
$pnode_token_obj->physical_oid()
```

Infoblox::Grid::Member->token_exp_date( )

Use this method to retrieve the date and time when the token will expire. The value is presented as a Unix timestamp.

Parameter

None

Returns

The method returns the attribute value, which is an integer number.

Example

```
# get the token_exp_date value for the token
$pnode_token_obj->token_exp_date()
```

Infoblox::Grid::Member->token( )

Use this method to retrieve the value (in text string) of the physical node token.

Parameter

None

Returns

The method returns the attribute value, which is a string.

Example

```
# get the token value itself
$pnode_token_obj->token()
```

SAMPLE CODE

The following sample code demonstrates how to create a token for the newly created pre-provisioned member.

```
#!/usr/bin/perl

use strict;
use Infoblox;

# get session for all subsequent operations
my $session = Infoblox::Session->new(master => 'localhost', username => 'admin', password => 'infoblox');

# create an object for the Grid member
my $grid_member = Infoblox::Grid::Member->new(
     name                    => "hostname.com",
     ipv4addr                => "3.0.0.2",
     mask                    => "255.0.0.0",
     gateway                 => "3.0.0.1",
     platform                => "VNIOS",
);
# add member
$session->add($grid_member);

# create pre-provisioning info objects
my $hw = Infoblox::Grid::Member::PreProvisioning::Hardware->new(
    hwtype          => 'IB-VNIOS',
    hwmodel         => 'CP-V1400',
);
my $pp = Infoblox::Grid::Member::PreProvisioning->new(
    hardware_info   => [$hw],
    licenses        => ['dns', 'dhcp'],
);
$grid_member->pre_provisioning($pp);
# ...and add pre-provisioning info to the Grid member
$session->modify($grid_member);

# Create tokens for the Grid member
# (actually the only token, as the member is not a HA-pair)
my $tokens_ref = $grid_member->create_token();

# Read all tokens for the grid member.
# Actually, we can skip the read_token call,
# as we already have tokens from previous
# create_token call in this example
# $tokens_ref = $grid_member->read_token();

if (defined $tokens_ref) {
   my @tokens = @$tokens_ref;
   # Iterate through all tokens in the array and
   # print their values.
   for (my $i = 0; $i < scalar @tokens; $i++) {
      print "Token $i:\n";
      print "physical_oid: " . $tokens[$i]->physical_oid(). "\n";
      print "token_exp_date: " . $tokens[$i]->token_exp_date() . "\n";
      print "token: " . $tokens[$i]->token() . "\n";
   }
}
```

NAME

Infoblox::Grid::Member::PreProvisioning - Pre-Provisioned member object.

DESCRIPTION

An Infoblox::Grid::Member::PreProvisioning object represents pre-provisioned data for a Grid member.

CONSTRUCTOR

```
my $pp = Infoblox::Grid::Member::PreProvisioning->new(
    hardware_info   => [$hw1, $hw2, ...],                  # Optional / an array of
Infoblox::Grid::Member::PreProvisioning::Hardware objects
    licenses        => [$lic1, $lic2, ...],                # Optional / Default value is undefined
);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Infoblox::Grid::Member::PreProvisioning object.

hardware_info( )

Use this method to set or retrieve the hardware information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array of Infoblox::Grid::Member::PreProvisioning::Hardware objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get get hardware_info()
my $hw = $pp->hardware_info();
#Modify hardware_info
$pp->hardware_info([$hw1, $hw2]);
```

licenses( )

Use this method to set or retrieve pre-provisioning licenses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array of valid licenses for each IB model type for the pre-provisioinig feature.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get get license()
my $lics = $pp->license();
#Modify hardwary_info
$pp->license(['dns', 'dhcp']);
```

Infoblox::Grid::Member::PreProvisioning::Hardware - PreProvisioning hardware info object.

DESCRIPTION

An Infoblox::Grid::Member::PreProvisioning::Hardware object represents pre-provisioned data for the hardware model.

CONSTRUCTOR

```
 my $hw = Infoblox::Grid::Member::PreProvisioning->new(
     hwtype          => $string,                  # Optional / one of IB-100,IB-810, IB-820, IB-1410, IB-1420, IB-2210, IB-FLEX,
                                                  # IB-2220, IB-4010, IB-4030, PT-1400, PT-2200, PT-4000, IB-RSP2, IB-VM, IB-VNIOS
     hwmodel         => $string,                  # Optional / one of:
                                                  # - for IB-4010 are Rev1, Rev2;
                                                  # - for IB-4030 are Rev1, Rev2;
                                                  # - for PT-4000 is Rev2;
                                                  # - for IB-RSP2 is [TBD];
                                                  # - for IB-VNIOS are IB-VM-100, IB-VM-810, IB-VM-820, IB-VM-RSP, IB-VM-1410, IB-VM-1420, IB-VM-2210, IB-VM-2220, IB-VM-4010;
 );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of an Infoblox::Grid::Member::PreProvisioning::Hardware object.

hwtype( )

Use this method to set or retrieve the hardware type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is a valid hardware type string.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get get hwtype()
my $hwt = $hw->hwtype();
#Modify hwtype
$hw->hwtype('PT-4000');
```

hwmodel( )

Use this method to set or retrieve the hardware model.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is a valid hardware model string.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get get hwmodel()
my $hwm = $hw->hwmodel();
#Modify hwmodel
$hw->hwmodel('Rev2');
```

NAME

Infoblox::Grid::Member::QueryFQDNParameter - A FQDN query parameters.

DESCRIPTION

A FQDN query call parameter objects. This object is intended to use only as Infoblox::Session->query_fqdn_on_member() parameter.

CONSTRUCTOR

```
 my $params = Infoblox::Grid::Member::QueryFQDNParameter->new(
     fqdn            => $string,                                          # Required
     member          => $string,                                          # Optional / Default is GM
     name_server     => $ipv4addr,                                        # Optional / Default is local
nameserver
     record_type     => 'ANY' | 'A' | 'AAAA' | 'CNAME' | 'DNAME' | 'MX' |
                        'NAPTR' | 'NS' | 'PTR' | 'SRV' | 'TXT' | 'AXFR'   # Optional / Default is 'ANY'
     recursive_query => 'true' | 'false',                                 # Optional / Default is 'true'
 );
```

MODULE METHODS

Infoblox::Session->query_fqdn_on_member( )

Use this method to query FQDN on the specified member.

This method forces Grid Master to execute RPC call to invoke dog on the member for a specific FQDN.

See Infoblox::Session->query_fqdn_on_member() for parameters and return values.

Example

```
#Construct parameters object
my $query_fqdn = Infoblox::Grid::Member::QueryFQDNParameter->new(
    fqdn        => 'bar.com',
    member      => 'member1',
    name_server => '5.5.5.5',
    record_type => 'A',
);

#Query
my $response = $session->query_fqdn_on_member($query_fqdn);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

fqdn( )

Use this method to set or retrieve a fully-qualified DNS query name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a FQDN to query in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get fqdn value
my $fqdn = $object->fqdn();

#Modify fqdn value
$object->fqdn($fqdn);
```

member( )

Use this method to set or retrieve a member name to invoke dig on.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains the Grid Member host name. Default is undefined, which causes dig invokation on Grid Master.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member value
my $member = $object->member();

#Modify member value
$object->member('localhost.localdomain');
```

name_server( )

Use this method to set or retrieve a nameserver to query.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains an IPv4 address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name_server value
my $value = $object->name_server();

#Modify name_server value
$object->name_server('5.5.5.5');
```

record_type( )

Use this method to set or retrieve the resource record type to query.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'ANY', 'A', 'AAAA', 'CNAME', 'DNAME', 'MX', 'NAPTR', 'NS', 'PTR', 'SRV', 'TXT' and 'AXFR'. The default value is 'ANY'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get record_type value
my $value = $object->record_type();

#Modify record_type value
$object->record_type('AAAA');
```

recursive_query( )

Use this method to set or retrieve the recursive query flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to set recursive query flag and 'false' to unset/deactivate it. The default value is 'true'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recursive_query value
my $value = $object->recursive_query();

#Modify recursive_query value
$object->recursive_query('false');
```

NAME

Infoblox::Grid::Member::QueryFQDNResponse - A FQDN query response.

DESCRIPTION

A FQDN query call response objects. This object is returned from Infoblox::Session->query_fqdn_on_member() function call.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

Note that this is a read-only object.

result( )

Use this method to set or retrieve a dig request return code.

Returns

The method returns the attribute value, which can be 'NOERROR', 'FORMERR', 'SERVFAIL', 'NXDOMAIN', 'NOTIMP', 'REFUSED' or 'INTERNAL_ERROR'.

Example

```
#Get result value
my $result = $object->result();
```

result_text( )

Use this method to set or retrieve a dig result multilined text.

Returns

The method returns the attribute value, a dig result text in string format.

Example

```
#Get result_text value
my $result_text = $object->result_text();
```

dig_started( )

Use this method to set or retrieve a timestamp since dig started.

Returns

The method returns the attribute value, the number of seconds that have elapsed since January 1st, 1970.

Example

```
#Get dig_started value
my $dig_started = $object->dig_started();
```

source_address( )

Use this method to set or retrieve a source IP address of the query.

Returns

The method returns the attribute value, the IP address in string format.

Example

```
#Get source_address value
my $source_address = $object->source_address();
```

NAME

Infoblox::Grid::Member::RestartServiceStatus - The restart status for member services.

DESCRIPTION

The object provides information about the restart status for member services.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to an object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific object:

 member - Optional. The Grid member name.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::Member::RestartServiceStatus',
    'member' => 'hostname.com',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for an object:

 member - Optional. The Grid member name.
```

Example

```
my @retrieved_objs = $session->search(
    'object' => 'Infoblox::Grid::Member::RestartServiceStatus',
    'member' => 'hostname.com',
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an object.

dhcp_status( )

Use this method to retrieve the restart status for the member DHCP service. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'CONFIG_ERROR', 'DISABLED', 'NO', 'NO_PERMISSION', 'NO_REQUEST', 'OFFLINE', 'REQUESTING', 'RESTART_PENDING' or 'YES'.

Example

```
# Get attribute value
my $value = $object->dhcp_status();
```

dns_status( )

Use this method to retrieve the restart status for the member DNS service. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'CONFIG_ERROR', 'DISABLED', 'NO', 'NO_PERMISSION', 'NO_REQUEST', 'OFFLINE', 'REQUESTING', 'RESTART_PENDING' or 'YES'.

Example

```
# Get attribute value
my $value = $object->dns_status();
```

member( )

Use this method to retrieve the Grid member name. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->member();
```

radius_status( )

Use this method to retrieve the restart status for the member RADIUS service. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'CONFIG_ERROR', 'DISABLED', 'NO', 'NO_PERMISSION', 'NO_REQUEST', 'OFFLINE', 'REQUESTING', 'RESTART_PENDING' or 'YES'.

Example

```
# Get attribute value
my $value = $object->radius_status();
```

reporting_status( )

Use this method to retrieve the restart status for the member reporting service. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'CONFIG_ERROR', 'DISABLED', 'NO', 'NO_PERMISSION', 'NO_REQUEST', 'OFFLINE', 'REQUESTING', 'RESTART_PENDING' or 'YES'.

Example

```
# Get attribute value
my $value = $object->reporting_status();
```

NAME

Infoblox::Grid::Member::ServiceStatus - Service Status object.

DESCRIPTION

This object is used to report the service status on an Infoblox appliance. All methods are to be considered read-only.

MODULE METHODS

The following functions can be applied to a ServiceStatus object.

Infoblox::Grid::Member->service_status( ), Infoblox::Grid::Member->node1_service_status( ), Infoblox::Grid::Member->node2_service_status( )

Use this function to retrieve a reference to an array of Infoblox::Grid::Member::ServiceStatus objects that represents the service status for an Infoblox appliance.

Example

```
#Retrieve the member object
my $member = $session->get(object => 'Infoblox::Grid::Member', name => 'hostname.com');

# Access its service status
my @services = @{$member->service_status()};
print $services[0]->status();
```

METHODS

This section describes all the methods that you can use to retrieve the attribute value of an appliance's service status.

description( )

Use this method to retrieve the description of the current ServiceStatus object.

Returns

The method returns the attribute value, which depends on the value of the 'service' method:

```
service value (for service_status) returned by this method
==========================================================
DHCP - DHCP service status
DNS - DNS service status
NTP - NTP service status
TFTP -  Percentage of the file distribution storage space that is used
HTTP_FILE_DIST - Percentage of the file distribution storage space that is used
FTP - Percentage of the file distribution storage space that is used
DNS_CACHE_ACCELERATION - DNS Cache Acceleration service status.

service value (for node1/2_service_status) returned by this method
===================================================================
NODE_STATUS - Node status
CPU1_TEMP - CPU1 temperature in Celsius
CPU2_TEMP - CPU2 temperature in Celsius
DISK_USAGE - Disk usage percentage
ENET_LAN - LAN1 interface IP
ENET_LAN2 - LAN2 interface IP
ENET_HA - HA interface IP
ENET_MGMT - MGMT interface IP
```

```
LCD - State of the LCD process (running/not running)
MEMORY - Memory usage percentage
REPLICATION - HA replication state
DB_OBJECT - Database capacity usage percentage
RAID_DISK1 - Disk status and type
RAID_DISK2 - Disk status and type
RAID_DISK3 - Disk status and type
RAID_DISK4 - Disk status and type
FAN1 - Fan 1 speed
FAN2 - Fan 2 speed
FAN3 - Fan 3 speed
POWER_SUPPLY - Power status
NTP_SYNC - Indicates if there are "reachable" NTP associations
TEMP_SYS - System temperature in Celsius
RAID_BATTERY - RAID battery status
CPU_USAGE - CPU Usage
BGP - BGP service status
OSPF - OSPF service status
OSPF6 - OSPFv6 service status
SWAP_USAGE - Swap Usage
```

Example

```
#Get description
my $description = $service_status->description();
```

status( )

Use this method to retrieve the service status.

Returns

The method returns the attribute value. Valid values are "Failed", "Warning", "Working", and "Inactive"

Example

```
#Get status
my $status = $service_status->status();
```

service( )

Use this method to retrieve the service identifier.

Returns

The method returns the attribute value. Possible values when the object is retrieved via service_status are:

ANALYTICS, ATP, CAPTIVE_PORTAL, CLOUD_API, DHCP, DISCOVERY, DNS, DNS_CACHE_ACCELERATION, FTP, HSM, HTTP_FILE_DIST, NTP, REPORTING, TAXII, TFTP

Possible values when the object is retrieved via node1/2_service_status are:

AUTH_NAMED, BGP, CORE_FILES, CPU1_TEMP, CPU2_TEMP, CPU_USAGE, CPU_USAGE, DB_OBJECT, DISCOVERY_CAPACITY, DISK_SIZE, DISK_USAGE, ENET_HA, ENET_LAN, ENET_LAN2, ENET_MGMT, EXTERNAL_STORAGE, FAN1, FAN2, FAN3, FAN4, FAN5, FAN6, FAN7, FAN8, JOIN_STATUS, LCD, MEMORY, MGM_SERVICE, NETWORK_CAPACITY, NODE_STATUS, NTP_SYNC, OSPF, OSPF6, PASSIVE_HA_CONNECTIVITY, POWER1, POWER2, POWER3, POWER4, POWER_SUPPLY, RAID_BATTERY, RAID_DISK1, RAID_DISK2, RAID_DISK3, RAID_DISK4, RAID_DISK5, RAID_DISK6, RAID_DISK7, RAID_DISK8, RAID_SUMMARY, REPLICATION, SFP_HA, SFP_LAN, SFP_LAN2, SFP_MGMT, SNIC_CHIP_TEMP, SNIC_CORE_UTIL, SNIC_PCB_TEMP, SNIC_UTIL, SUBGRID_CONN, SWAP_USAGE, SYS_TEMP, VPN_CERT

Example

```
#Get service
my $service = $service_status->service();
```

- COPYRIGHT

NAME

Infoblox::Grid::Member::StaticRoute - Static route member object

DESCRIPTION

A StaticRoute object provides static route information for a grid member.

CONSTRUCTOR

```
my $route = Infoblox::Grid::Member::StaticRoute->new(
        "network" => $network,          #Required
        "gateway" => $ip_address,       #Required
);
```

MODULE METHODS

The following functions can be applied to a StaticRoute object.

Infoblox::Grid::Member->static_routes( )

Use this function to specify a StaticRoute object for the grid member. See Infoblox::Grid::Member->static_routes() for parameters and return values.

Example

```
#Get static routes list
my $static_routes = $grid_member->static_routes();
#Modify static routes list
my $route = Infoblox::Grid::Member::StaticRoute->new(
        "network" => "192.168.2.0/24",
        "gateway" => "192.168.1.1",
);
$grid_member->static_routes([$route]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a StaticRoute object.

network( )

Use this method to set or retrieve the network address of a StaticRoute object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the address and netmask of network in CIDR format (example: 192.168.2.0/24).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network address
my $network= $route->network();
#Modify network address
$route-->network("192.168.2.0/24");
```

gateway( )

Use this method to set or retrieve the gateway of the StaticRoute object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the gateway address in IPv4 address format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get gateway address
my $gateway= $route->gateway();
#Modify gateway address
$route-->gateway("192.168.2.0");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a StaticRoute object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a StaticRoute object insertion

```
use strict;
use warnings;
use Infoblox;

my $host_name = "infoblox.localdomain";
my $host_ip   = "192.168.1.2";
#Creating a session to the Infoblox appliance.
my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);

unless ($session) {
    die(qq(constructor for session failed: ),
        join(":", Infoblox::status_code(), Infoblox::status_detail()));
}
print "Session created successfully \n";
```

#Create a StaticRoute object

```
#Creating a StaticRoute object.
my $route = Infoblox::Grid::Member::StaticRoute->new(
       "network" => "192.168.2.0/24",
       "gateway" => "192.168.1.1",
) or die(qq(Constructor for StaticRoute failed: ),
   join(":", Infoblox::status_code(), Infoblox::status_detail()));
print "StaticRoute object constructed successfully \n";
```

#Add a StaticRoute object to the static routes list of the grid member

```
#Getting the Grid Member object from the appliance through a session.
my @result = $session->get(
    object => "Infoblox::Grid::Member",
    name   => $host_name,
    ) or die(qq(Get Grid Member failed: ),
    join(":", $session->status_code(), $session->status_detail()));
print "Get Grid Member successful\n";
```

```
my $result = $result[0];
if ($result) {
    #Modifying the value of the StaticRoute method from the member object.
    $result->static_routes([$route]);
    #Applying the changes to appliance through session.
    $session->modify($result)
        or die(qq(Modify Grid Member failed: ),
        join(":", $session->status_code(), $session->status_detail()));
}
print "StaticRoute object added to Grid Member successfully\n";
```

#Remove the static routes list

```
#Remove the StaticRoute object from the Grid Member object.
$result->static_routes([]);

#Update the Grid Member object through the Infoblox session.
$session->modify($result)
  or die("Modify Grid Member object failed: ",
  $session->status_code() . ":" . $session->status_detail());
print "Removed StaticRoute object from Grid Member successfully\n";

####PROGRAM ENDS####
```

NAME

Infoblox::Grid::Member::Taxii - A Taxii Member object.

DESCRIPTION

The Taxii Member object provides information on Taxii service configuration such as the start/stop flag and RPZ (Response Policy Zone) configuration.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a Taxii Member object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

  ipv4addr - Optional. IPv4 Member address.
  ipv6addr - Optional. IPv6 Member address.
  name     - Optional. The host name of the parent member.
```

Example

```
#Get Taxii Member object with name 'taxii_member.com'
my @taxii_member = $session->get(
    object => 'Infoblox::Grid::Member::Taxii',
    name   => 'taxii_member.com',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify enable_service value
$taxii_member->enable_service('true');

#Submit modification
$session->modify($taxii_member);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to search a specific object:
```

```
  ipv4addr - Optional. IPv4 Member address (regular expression).
  ipv6addr - Optional. IPv6 Member address (regular expression).
  name     - Optional. The host name of the parent member.
```

Example

```
#Search for Taxii Member object with name starting with 'taxii'
my @taxii_member = $session->get(
    object => 'Infoblox::Grid::Member::Taxii',
    name   => 'taxii.*',
);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

enable_service( )

Use this method to set or retrieve the flag that indicates whether the Taxii service is running on the given member or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to start/enable Taxii service or 'false' to stop/deactivate it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_service value
my $enable_service = $object->enable_service();

#Modify enable_service value
$object->enable_service('true');
```

ipv4addr( )

Use this method to retrieve the IPv4 address of the Taxii member. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get ipv4addr value
my $ipv4addr = $object->ipv4addr();
```

ipv6addr( )

Use this method to retrieve the IPv6 address of the Taxii member. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get ipv6addr value
my $ipv6addr = $object->ipv6addr();
```

name( )

Use this method to retrieve the name of the Taxii member. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();
```

taxii_rpz_config( )

Use this method to set or retrieve the Taxii service RPZ configuration list.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::Member::Taxii::RPZConfig.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get taxii_rpz_config value
my $taxii_rpz_config = $object->taxii_rpz_config();

#Modify taxii_rpz_config value
$object->taxii_rpz_config([$conf1, $conf2]);
```

NAME

Infoblox::Grid::Member::Taxii::RPZConfig - A Taxii Member RPZ Configuration object.

DESCRIPTION

The Taxii Member RPZ Configuration object provides configuration for RPZ rule creation through the Taxii protocol. Each Grid member running the Taxii server can support a separate set of response policy zones. These zones will be accessible via a user configurable name for the STIX collection.

CONSTRUCTOR

```
my $rpz_config = Infoblox::Grid::Member::Taxii::RPZConfig->new(
    collection_name => $string, #Required
    zone            => $rpzone, #Required
);
```

MODULE METHODS

Infoblox::Grid::Member::Taxii->taxii_rpz_config( )

Use this method to set or retrieve the Taxii service RPZ configuration list. See Infoblox::Grid::Member::Taxii->taxii_rpz_config() for parameters and return values.

Example

```
#Get taxii_rpz_config value
my $taxii_rpz_config = $object->taxii_rpz_config();

#Modify taxii_rpz_config value
$object->taxii_rpz_config([$conf1, $conf2]);
```

METHODS

collection_name( )

Use this method to set or retrieve the STIX collection name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired collection name in sstring format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get collection_name value
my $collection_name = $object->collection_name();

#Modify collection_name value
```

```
$object->collection_name('collection1');
```

zone( )

Use this method to set or retrieve the response policy zone that can be modified through the Taxii protocol.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::DNS::Zone object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get zone value
my $zone = $object->zone();

#Modify zone value
$object->zone($rp_zone);
```

NAME

Infoblox::Grid::Member::ThreatProtection - Member Threat Protection object.

DESCRIPTION

This object provides information about the member Threat protection settings.

SESSION METHODS

The following functions can be applied to a Grid::Member::ThreatProtection object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Member Threat Protection object.

 grid_member    - Optional. The Grid member name.
 hardware_model - Optional. The Grid member hardware model name.
 hardware_type  - Optional. The Grid member hardware type.
 profile        - Optional. The Threat Protection profile object.
```

Example

```
my @retrieved_objs = $session->get(
    'object'      => 'Infoblox::Grid::Member::ThreatProtection',
    'grid_member' => 'host.com',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify attributes of an member object.
$member->enable_service('true');
$member->override_events_per_second_per_rule('true');
$member->events_per_second_per_rule('2');
$member->override_disable_multiple_dns_tcp_request('true');
```

```
$member->disable_multiple_dns_tcp_request('true');

# Submit modification
my $response = $session->modify( $member );
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search a specific Member Threat Protection object.

 grid_member    - Optional. The Grid member name.
 hardware_model - Optional. The Grid member hardware model name (regular expression).
 hardware_type  - Optional. The Grid member hardware type (regular expression).
 profile        - Optional. The Threat Protection profile object.
```

Example

```
my @retrieved_objs = $session->search(
    'object'      => 'Infoblox::Grid::Member::ThreatProtection',
    'grid_member' => 'host.com',
);
```

METHODS

This object provides information about the member threat protection settings.

current_ruleset( )

Use this method to set or retrieve the current member ruleset.

Setting this method to a defined value implicitly sets the override_current_ruleset method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_current_ruleset attribute to "false".

Note that when current_ruleset is set to a defined value and override_dcurrent_ruleset is set to "false", the last operation takes precedence. Thus the sequence $object->current_ruleset($rs); $object->override_current_ruleset("false"); will set override_current_ruleset to "false", and the sequence $object->override_current_ruleset("false"); $object->current_ruleset($rs); will result in override_current_ruleset="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::ThreatProtection::Ruleset object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $obj->current_ruleset();
#Modify attribute value
$obj->current_ruleset($rs);
```

enable_nat_rules( )

Use this method to enable or disable NAT (Network Address Translation) mapping for threat protection at the member level.

Setting this method to a defined value implicitly sets the override_enable_nat_rules method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_enable_nat_rules attribute to "false".

Note that when enable_nat_rules is set to a defined value and override_denable_nat_rules is set to "false", the last operation takes precedence. Thus the sequence $object->enable_nat_rules($nat_rules); $object->override_enable_nat_rules("false"); will set override_enable_nat_rules to "false", and the sequence $object->override_enable_nat_rules("false"); $object->enable_nat_rules($nat_rules); will result in override_enable_nat_rules="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Paramter

Specify 'true' to enable NAT mapping for threat protection or 'false' to disable it. The default value is 'false.'

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->enable_nat_rules();

#Modify attribute value
$object->enable_nat_rules('true');
```

enable_service( )

Use this method to enable or disable the Threat protection service on the member.

Parameter

Set the parameter to "true" to enable Threat protection service on the member. Set the parameter to "false" to disable the service.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->enable_service();
# Modify attribute value
$object->enable_service('true');
```

events_per_second_per_rule( )

Use this method to set or retrieve the number of events logged per second per rule.

Parameter

The number of events logged per second per rule in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->events_per_second_per_rule();
# Modify attribute value
$object->events_per_second_per_rule('2');
```

grid_member( )

Use this method to retrieve a Grid member name. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->grid_member();
```

hardware_model( )

Use this method to retrieve the hardware model name of the Grid member. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get hardware_model value
my $value = $object->hardware_model();
```

hardware_type( )

Use this method to retrieve the type of the Grid member hardware. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get hardware_type value
my $value = $object->hardware_type();
```

override_events_per_second_per_rule( )

Use this method to set or retrieve the override flag for the number of events logged per second per rule.

Parameter

Specify "true" to set the override_events_per_second_per_rule flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->override_events_per_second_per_rule();
# Modify attribute value
$object->override_events_per_second_per_rule('true');
```

disable_multiple_dns_tcp_request( )

Use this method to disable multiple BIND responses via TCP connection.

Setting this method to a defined value implicitly sets the override_disable_multiple_dns_tcp_request method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_disable_multiple_dns_tcp_request attribute to "false".

Note that when config is set to a defined value and override_disable_multiple_dns_tcp_request is set to "false", the last operation takes precedence. Thus the sequence $object->disable_multiple_dns_tcp_request($value); $object->override_disable_multiple_dns_tcp_request("false"); will set override_disable_multiple_dns_tcp_request to "false", and the sequence $object->override_disable_multiple_dns_tcp_request("false"); $object->disable_multiple_dns_tcp_request($value); will result in override_disable_multiple_dns_tcp_request="true".

Parameter

Set the parameter to "true" to disable multiple TCP requests. Set the parameter to "false" to enable multiple TCP requests.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
```

```
my $value = $object->disable_multiple_dns_tcp_request();
# Modify attribute value
$object->disable_multiple_dns_tcp_request('true');
```

nat_rules( )

Use this method to set or retrieve the list of NAT mapping rules cofigured for the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::ThreatProtection::NATRule objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $obj->nat_rules();
#Modify attribute value
$obj->nat_rules($nat_rules);
```

override_current_ruleset( )

The override_current_ruleset attribute controls whether the member's current ruleset value is used, instead of the Grid default.

The override_current_ruleset attribute can be specified explicitly. It is also set implicitly when current_ruleset is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_current_ruleset flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_current_ruleset from the member
my $override = $object->override_current_ruleset();
#Modify override_current_ruleset
$object->override_current_ruleset("true");
```

override_disable_multiple_dns_tcp_request( )

Use this method to set or retrieve the override flag for disabling multiple BIND responses via TCP connection.

Parameter

Specify "true" to set the override_disable_multiple_dns_tcp_request flag or "false" to unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->override_disable_multiple_dns_tcp_request();
# Modify attribute value
$object->override_disable_multiple_dns_tcp_request('true');
```

override_enable_nat_rules( )

The override_enable_nat_rules attribute controls whether the member's current enable_nat_rules value is used, instead of the Grid default.

The override_enable_nat_rules attribute can be specified explicitly. It is also set implicitly when enable_nat_rules is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_enable_nat_rules flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_nat_rules from the member
my $override = $object->override_enable_nat_rules();
#Modify override_enable_nat_rules
$object->override_enable_nat_rules("true");
```

profile( )

Use this method to set or retrieve the Threat Protection profile that is used to group this member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ThreatProtection::Profile object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get profile value
my $value = $object->profile();

#Modify profile value
$object->profile($profile);
```

NAME

Infoblox::Grid::Member::ThreatProtection::Rule - Member Threat Protection Rule object.

DESCRIPTION

This object provides information about the member Threat protection rule settings.

SESSION METHODS

The following functions can be applied to a Grid::Member::ThreatProtection::Rule object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Member Threat Protection::Rule object.
 sid    - Optional. The Rule ID.
 rule   - Optional. The Threat Protection Rule object.
 member - Optional. The Member Threat Protection object.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::Member::ThreatProtection::Rule',
    'sid' => '211111'
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
 my $rule = $session->search('object' => 'Infoblox::Grid::ThreatProtection::Rule', 'sid' =>
'211111');
 my $member = $session->get('object' => 'Infoblox::Grid::Member::ThreatProtection');
 my $member_rule = $session->search('object' => 'Infoblox::Grid::Member::ThreatProtection::Rule',
'member' => $member, 'rule' => $rule);

 my $conf = $member_rule->config();
 $conf->action('PASS');

 # Use this method to modify attributes of object.
 $member_rule->disable('true');
 $member_rule->override_disable('true');
 $member_rule->config($conf);
 $member_rule->override_config('true');
```

```
# Submit modification
my $response = $session->modify( $member_rule );
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid Threat Protection::Rule object.
 sid    - Optional. The Rule ID.
 rule   - Optional. The Threat Protection Rule object.
 member - Optional. The Member Threat Protection object.
```

Example

```
my $rule = $session->search('object' => 'Infoblox::Grid::ThreatProtection::Rule', 'sid' =>
'211111');
my $member = $session->get('object' => 'Infoblox::Grid::Member::ThreatProtection');
my $member_rule = $session->search('object' => 'Infoblox::Grid::Member::ThreatProtection::Rule',
    'member' => $member,
    'rule' => $rule,
);
```

METHODS

config( )

Use this method to set or retrieve rule configuration information.

Setting this method to a defined value implicitly sets the override_config method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_config attribute to "false".

Note that when config is set to a defined value and override_config is set to "false", the last operation takes precedence. Thus the sequence $object->config($value); $object->override_config("false"); will set override_config to "false", and the sequence $object->override_config("false"); $object->config($value); will result in override_config="true".

Parameter

Valid value is reference on Infoblox::Grid::ThreatProtection::RuleConfig object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->config();
$value->log_severity('INFORMATIONAL');
# Modify attribute value
$object->config($value);
```

disable( )

Use this method to set or indicate whether the rule is enabled or disabled for the member.

Setting this method to a defined value implicitly sets the override_disable method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_disable attribute to "false".

Note that when disable is set to a defined value and override_disable is set to "false", the last operation takes precedence. Thus the sequence $object->disable('true'); $object->override_disable("false"); will set override_disable to "false", and the sequence $object->override_disable("false"); $object->disable('true'); will result in override_disable="true".

Parameter

Valid value is "true" or "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->disable();
# Modify attribute value
$object->disable(true);
```

member( )

Use this method to retrieve reference to the member object. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->member();
```

override_config( )

Use this method to set or retrieve the override flag for the rule configuration.

Parameter

Valid value is "true" or "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->override_config();
# Modify attribute value
$object->override_config(true);
```

override_disable( )

Use this method to set or retrieve the override flag for the disabled field.

Parameter

Valid value is "true" or "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->override_disable();
# Modify attribute value
$object->override_disable(true);
```

rule( )

Use this method to retrieve reference to the rule object. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->rule();
```

sid( )

Use this method to retrieve the Rule ID. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->sid();
```

NAME

Infoblox::Grid::MSServer - Microsoft (r) Grid Server object.

DESCRIPTION

A grid Microsoft DNS Server object is a single Microsoft DNS server that is managed by a grid member.

CONSTRUCTOR

```
 my $ms_member = Infoblox::Grid::MSServer->new(
     address                 => $ip_or_fqdn,                                 #Required
     ad_sites                => $ad_sites,                                   #Optional
     ad_user                 => $ad_user,                                    #Optional
     comment                 => $string,                                     #Optional / Default value
is empty
     disable                 => "true" | "false"                             #Optional / Default value
is "false"
     extattrs                => { $string => $extattr, ... },                #Optional / Default is
undefined
     extensible_attributes   => { $string => $string | $num,
                                  $string => [ $string | $num, ... ], ... }, #Optional / Default is
undefined
```

```
     login                    => $string,                                    #Required
     password                 => $string,                                    #Optional / Default value
is empty
     managing_member          => $Member,                                    #Optional / Default value
is empty
     read_only                => "true" | "false",                           #Optional / Default value
is "true"
     synchronization_interval => $num,                                       #Optional / Default value
is 2
     logging_mode             => "minimum" | "normal" | "advanced" | "full", #Optional / Default value
is "normal"
     network_view             => $NetworkView,                               #Optional / Default is
"default" network view
     dns_view                 => $DnsView,                                   #Optional / Default is
"default" view
     log_destination          =>  "SYSLOG" | "MSLOG",                        #Optional / Default is
undefined
     override_log_destination => "true" | "false",                           #Optional / Default value
is "false"
     max_connection           => $num,                                       #Optional / Default is
undefined
     override_max_connection  => "true" | "false",                           #Optional / Default value
is "false"
     rpc_timeout              => $num,                                       #Optional / Default is
undefined
     override_rpc_timeout     => "true" | "false",                           #Optional / Default value
is "false"
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

Infoblox::DNS::Zone Considerations

The following apply to zones assigned to Microsoft DNS servers:

Methods with no effect

The following methods have no effect on a Microsoft DNS server that is assigned to a zone:

allow_transfer()
allow_query( )
allow_update( )
allow_update_forwarding( )
bind_check_names_policy( )
create_underscore_zones( )
disable_forwarding( )
forward_only( )
forward_to( )
import_from( )
override_delegated_ttl( )
override_grid_zone_timer( )
override_grid_email( )
override_serial_number( )
prefix( )
remove_sub_zones( )
soa_negative_ttl( )
shared_record_groups( )

Values set or retrieved using the member that manages the Microsoft DNS server apply only to that grid member if it is assigned to a zone.

Applicable methods

The following methods apply to any grid member or Microsoft DNS server assigned to the zone:

comment( )
delegated_ttl( )
disable( )
email( )
extensible_attributes( )
host_name_restriction_policy( )
locked( )
name( )
ns_group( )
multiple_primaries( )
secondaries( )
soa_default_ttl( )

soa_expire( )
member_soa_mnames( )
soa_refresh( )
soa_retry( )
member_soa_serials( )
stub_from( )
stub_members( )
zone( )

Infoblox::DNS considerations

The following objects cannot be used with a Microsoft DNS Server object or with a Zone object whose primary server is a Microsoft DNS Server object:

Infoblox::DNS::BulkHost
Infoblox::DNS::DnssecTrustedKey
Infoblox::DNS::Host
Infoblox::DNS::SRG
Infoblox::DNS::RootNameServer
Infoblox::DNS::Sortlist
Infoblox::DNS::TSIGKey
Infoblox::DNS::Record

DNAME (only with Windows Server 2008 and later)
DS, RRSIG, DNSKEY, NSEC, NSEC3, NSEC3PARAM (read-only on Windows Server 2008 R2 and later)

Infoblox::Grid::DNS considerations

The following methods can be applied to DNS zones managed by a Microsoft DNS server:

default_ttl( )
email( )
host_name_restriction_policy( )
zone_deletion_double_confirm( )

The following methods have no effect on any zone managed by a Microsoft DNS server:

allow_bulkhost_ddns( )
allow_gss_tsig_zone_updates( )
allow_transfer( )
allow_query( )
allow_recursive_query( )
allow_update( )
bind_check_names_policy( )
blackhole_list( )
bulk_host_name_template( )
bulk_host_name_templates( )
dnssec_enabled( )
dnssec_expired_signatures_enabled( )
`dnssec_ksk_algorithm()`
`dnssec_ksk_rollover_interval()`
`dnssec_ksk_size()`
dnssec_signature_expiration( )
dnssec_validation_enabled( )
dnssec_trusted_keys( )
`dnssec_zsk_algorithm()`
`dnssec_zsk_rollover_interval()`
`dnssec_zsk_size()`
enable_blackhole( )
expire_after( )
forward_only( )
forward_updates( )
forwarders( )
logging_categories( )
logging_facility( )
member_secondary_notify( )
negative_ttl( )
notify_source_port( )
nsgroup_default( )
nsgroups( )
query_source_port( )
record_name_policies( )
recursive_query_list( )
refresh_timer( )

retry_timer( )
rootNS( )
sortlist( )
transfer_excluded_servers( )
transfer_format( )

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a grid member object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $grid_msserver = Infoblox::Grid::MSServer->new(
                                                  address                  => '10.0.0.1',
                                                  comment                  => 'This is an MS DNS Server',
                                                  disable                  => 'true',
                                                  extensible_attributes    => { Site => 'Main Office'},
                                                  login                    => 'user',
                                                  password                 => 'password',
                                                  managing_member          => 'managing.member.com',
                                                  read_only                => 'false',
                                                  synchronization_interval => 5,
                                                  logging_mode             => 'minimum',
    );
#Submit for addition
my $response = $session->add( $grid_msserver );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific grid member object:

 address - Optional. A member address or name in FQDN format.
 comment - Optional. A comment in string format
 read_only - Optional. A boolean value
 managing_member - Optional. A name in FQDN format.
 network_view  -  Optional. The network view served by the member.
 dns_view -  Optional. The DNS view served by the member.
 extattrs - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->get(
    object  => "Infoblox::Grid::MSServer",
    address => "10.0.0.1");
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment of a Microsoft DNS server managed by the grid.
$grid_msserver->comment("This is modified object");
# Submit modification
my $response = $session->modify( $grid_msserver );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
```

```
    object => "Infoblox::Grid::MSServer",
    name   => "10.0.0.1");
#Find the desired object from the retrieved list.
my $desired_gridmsserver = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_gridmsserver );
```

Infoblox::Session->search( )

Use this method to search for Microsoft DNS Server objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

Apply the following attributes to search for a Microsoft DNS Server object

```
address - Optional. A member address or name in FQDN format (regular expression).
comment - Optional. A comment in string format (regular expression).
read_only - Optional. A boolean value
managing_member - Optional. The FQDN of the grid member that manages the Microsoft DNS server?
network_view  -  Optional. The network view served by the member.
dns_view -  Optional. The DNS view served by the member.
extattrs - Optional. A hash reference containing extensible attributes.
extensible_attributes   - Optional. A hash reference that contains extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all matching grid msserver objects
my @retrieved_objs = $session->search(
    object  => "Infoblox::Grid::MSServer",
    extensible_attributes => { Site => 'Local'},
    );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Microsoft DNS server.

address()

Retrieve or set the IP address or FQDN of the Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The Microsoft DNS server name in FQDN format or IPV4 format

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address
my $address = $msserver->address();
```

ad_domain( )

Use this method to retrieve the Active Directory domain name of the Microsoft Server. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get ad_domin value
my $ad_domain = $object->ad_domain();
```

ad_sites()

Use this method to set or retrieve structure containing Active Directory Sites information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::MSServer::AdSites object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ad_sites value
my $ad_sites = $msserver->ad_sites();

#Modify ad_sites value
my $res = $msserver->ad_sites($ad_sites);
```

ad_user()

Use this method to set or retrieve the object that contains Active Directory User synchronization information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::MSServer::AdUser object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ad_user value
my $ad_user = $msserver->ad_user();

#Modify ad_user value
my $res = $msserver->ad_user($ad_user);
```

comment()

Retrieve or set a user-defined string related to this Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $msserver->comment();
#Modify comment
$msserver->comment("Modifying the MS DNS server comment");
```

disable()

Retrieve or set the `disable()` flag of this Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $msserver->disable();
#Modify disable
$msserver->disable("true");
```

login()

Retrieve or set the login name that the grid member uses to connect to the Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

When setting a value that requires a domain name, prepend the domain information followed by a backslash to the username: "domain\username".

Parameter

The valid value is a string that contains the login name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get login
my $login = $msserver->login();
#Modify login
$msserver->login("newuser");
```

password()

Set the password that the grid member uses to connect to the Microsoft DNS server. This field is used only if the login field for this member is defined. This is a write-only attribute.

This field can not be retrieved.

Parameter

The valid value is a string that contains the password.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set the password
$msserver->password("iG&ojG97Y");
```

network_view()

Retrieve or set the name of the network view associated with this member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains the name of the network view associated with this member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network_view
```

```
my $network_view = $msserver->network_view();
#Modify network_view
$msserver->network_view("external");
```

dns_view()

Retrieve or set the name of the DNS view that applies to this Microsoft DNS server. If this field is set to undefined, the default view is used. The DNS view must be set to a DNS view linked to the Microsoft DNS server network view.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains the name of the DNS view associated with the Microsoft DNS server

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dns_view
my $dns_view = $msserver->dns_view();
#Modify dns_view
$msserver->dns_view("external");
```

log_destination( )

Use this method to direct the logging of synchronization messages to the syslog or mslog.

Setting this method to a defined value implicitly sets the override_log_destination method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_log_destination method to "false".

Note that when log_destination is set to a defined value and override_log_destination is set to "false", the last operation takes precedence. Thus the sequence $object->log_destination("MSLOG"); $object->override_log_destination("false"); will set override_log_destination to "false", and the sequence $object->override_log_destination("false"); $object->log_destination("MSLOG"); will result in override_log_destination="true".

Parameter

Valid values are "SYSLOG" and "MSLOG".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get log_destination value
my $log_destination = $msserver->log_destination();
#Modify log_destination value
$msserver->log_destination("SYSLOG");
```

max_connection( )

Use this method to set or retrieve the maximum number of connections to a Microsoft server.

Setting this method to a defined value implicitly sets the override_max_connection method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_max_connection method to "false".

Note that when max_connection is set to a defined value and override_max_connection is set to "false", the last operation takes precedence. Thus the sequence $object->max_connection(20); $object->override_max_connection("false"); will set override_max_connection to "false", and the sequence $object->override_max_connection("false"); $object->max_connection(20); will result in override_max_connection="true".

Parameter

Valid values are integers between 2 and 40 inclusive.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_connection value
my $max_connection = $msserver->max_connection();
#Modify max_connection value
$msserver->max_connection(20);
```

managing_member()

Retrieve or set the grid member responsible for the synchronization of this Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains the name of the grid member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get managing_member
my $managing_member = $msserver->managing_member();
#Modify managing_member
$msserver->managing_member("example.member.com");
```

override_log_destination( )

The override_log_destination attribute controls whether the log_destination method values of the Microsoft Server are used, instead of the Grid default.

The override_log_destination attribute can be specified explicitly. It is also set implicitly when log_destination is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for log_destination. Set the parameter to "false" to inherit the Grid-level setting for log_destination. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_log_destination
my $override_log_destination = $msserver->override_log_destination();
#Modify override_log_destination
$msserver->override_log_destination("true");
```

override_max_connection( )

The override_max_connection attribute controls whether the max_connection method values of the Microsoft Server are used, instead of the Grid default.

The override_max_connection attribute can be specified explicitly. It is also set implicitly when max_connection is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for max_connection. Set the parameter to "false" to inherit the grid-level setting for max_connection. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_max_connection
my $override_max_connection = $msserver->override_max_connection();
#Modify override_max_connection
$msserver->override_max_connection("true");
```

override_rpc_timeout( )

The override_rpc_timeout attribute controls whether the rpc_timeout method values of the Microsoft Server are used, instead of the Grid default.

The override_rpc_timeout attribute can be specified explicitly. It is also set implicitly when rpc_timeout is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for rpc_timeout. Set the parameter to "false" to inherit the grid-level setting for rpc_timeout. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_rpc_timeout
my $override_rpc_timeout = $msserver->override_rpc_timeout();
#Modify override_rpc_timeout
$msserver->override_rpc_timeout("true");
```

read_only()

Retrieve or set the synchronization mode of this Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting the read_only mode to true synchronizes all data from the Microsoft DNS server to the grid and forbids any change on the grid that could be synchronized to the Microsoft DNS server.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get read_only
my $read_only = $msserver->read_only();
#Modify read_only
$msserver->read_only("false");
```

root_ad_domain( )

Use this method to retrieve the Active Directory root domain name of the Microsoft Server. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get ad_domin value
my $root_ad_domain = $object->root_ad_domain();
```

rpc_timeout( )

Use this method to set or retrieve the timeout value in seconds for RPC connections to Microsoft Server.

Setting this method to a defined value implicitly sets the override_rpc_timeout method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_rpc_timeout method to "false".

Note that when rpc_timeout is set to a defined value and override_rpc_timeout is set to "false", the last operation takes precedence. Thus the sequence $object->rpc_timeout(10); $object->override_rpc_timeout("false"); will set override_rpc_timeout to "false", and the sequence $object->override_rpc_timeout("false"); $object->rpc_timeout(10); will result in override_rpc_timeout="true".

Parameter

Valid values are integers between 0 and 65535 inclusive.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rpc_timeout value
my $rpc_timeout = $msserver->rpc_timeout();
#Modify rpc_timeout value
$msserver->rpc_timeout(10);
```

synchronization_interval()

Retrieve or set the synchronization interval of this Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The synchronization interval controls how often data on the Microsoft DNS server is synchronized with the grid. The value is specified in minutes.

Parameter

The valid value is a number that specifies the synchronization interval in minutes. The default value is 2 minutes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get synchronization_interval
my $synchronization_interval = $msserver->synchronization_interval();
#Modify synchronization_interval
$msserver->synchronization_interval(5);
```

logging_mode()

Retrieve or set the synchronization logging verbosity of this Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is "minimum", "normal", "advanced", or "full". The default value is "normal".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logging_mode
my $logging_mode = $msserver->logging_mode();
#Modify logging_mode
$msserver->logging_mode("advanced");
```

version()

Retrieve the version of this Microsoft DNS server. The returned version is a string, such as "Microsoft Windows Server 2003".

Returns

The method returns the attribute value.

Example

```
#Get version
my $version = $msserver->version();
```

is_AD()

Retrieve the Active Directory flag of the Microsoft DNS server. The method returns "true" if the Microsoft DNS server has Active Directory capabilities or "false" if it does not.

Returns

The method returns the attribute value.

Example

```
#Get is_AD
my $is_AD = $msserver->is_AD();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Microsoft DNS server object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $msserver->extattrs();
#Modify extattrs
$msserver->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $msserver->extensible_attributes();
#Modify extensible attributes
$msserver->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify, search and remove. This sample also includes error handling for the operations.

#Preparation prior to getting and modifying a grid msserver object

```
use strict;
use Infoblox;
```

```
#refers to Infoblox Appliance IP address
my $host_ip = "192.168.1.2";

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a grid member object

my $grid_member = Infoblox::Grid::Member->new(
    name          => "hostname.com",
    ipv4addr      => "3.0.0.2",
    mask          => "255.0.0.0",
    gateway       => "3.0.0.1",
    comment       => "Script Generated"
    );
unless ($grid_member) {
       die("Construct grid member object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Grid member object created successfully\n";

#Adding the member object to appliance through session
my $response = $session->add( $grid_member );

unless ($response) {
    die("Add grid member failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Grid member added successfully \n";

my $msserver = Infoblox::Grid::MSServer->new(
                                          address                  => '10.0.0.1',
                                          comment                  => 'basic member',
                                          disable                  => 'true',
                                          extensible_attributes    => { Site => 'Local'},
                                          login                    => 'user',
                                          password                 => 'password',
                                          managing_member          => 'hostname.com',
                                          read_only                => 'false',
                                          synchronization_interval => 5,
                                          logging_mode             => 'minimum',
                                         );

unless ($msserver) {
       die("Construct grid MS DNS server object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Grid MS DNS server object created successfully\n";

#Adding the member object to appliance through session
$response = $session->add( $msserver );

unless ($response) {
    die("Add grid MS DNS server failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Grid MS DNS server added successfully \n";
```

#Search for a grid Microsoft DNS server object

```
 my @retrieved_objs = $session->search(
     object => "Infoblox::Grid::MSServer",
     comment => "basic.*");
 my $object = $retrieved_objs[0];

 unless ($object) {
        die
```

```
            ("Search grid MS DNS server object failed: ",
                $session->status_code() . ":" . $session->status_detail());
 }
 print "Search grid MS DNS server object found at least 1 matching entry\n";
```

#Get and modify the msserver object

```
#Get grid member through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::MSServer",
    address => "10.0.0.1"
    );
my $msserver = $retrieved_objs[0];

unless ($msserver) {
    die("Get grid MS DNS server object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Get grid MS DNS server successful \n";

# Modify one of the attributes of the selected Microsoft DNS server.

$msserver->comment("Modified MS DNS server object");

#Applying the changes
$session->modify($msserver)
   or die("Modify grid MS DNS server failed",
            $session->status_code() . ":" . $session->status_detail());
print"Grid MS DNS server modified successfully \n";
```

#Remove the created objects object

```
#Get grid member through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::MSServer",
    address => "10.0.0.1"
    );
my $desired_msserver = $retrieved_objs[0];

unless ($desired_msserver) {
    die("Get grid MS DNS server object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Get grid member successful \n";

#Submit the object for removal
$session->remove( $desired_msserver )
    or die("Remove grid MS DNS server failed",
           $session->status_code() . ":" . $session->status_detail());
print"Grid MS DNS server removed successfully \n";

#Get grid member through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member",
    name   => "hostname.com"
    );
my $desired_grid_member = $retrieved_objs[0];

unless ($desired_grid_member) {
    die("Get grid member object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Get grid member successful \n";

#Submit the object for removal
$session->remove( $desired_grid_member )
    or die("Remove grid member failed",
           $session->status_code() . ":" . $session->status_detail());
print"Grid member removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::MSServer::AdSites - the Active Directory Site object.

DESCRIPTION

The object provides information about the Active Directory Site.

SESSION METHODS

The object does not support any session methods. It is retrieved as a part of the Microsoft Server object.

METHODS

this section describes all the methods that you can use to set or retrieve the attribute values of the object.

default_ip_site_link( )

Use this method to set or retrieve the default IP site link name.

Setting this method to a defined value implicitly sets the override_default_ip_site_link method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_default_ip_site_link attribute to "false".

Note that when default_ip_site_link is set to a defined value and override_ddefault_ip_site_link is set to "false", the last operation takes precedence. Thus the sequence $object->default_ip_site_link('LAX'); $object->override_default_ip_site_link("false"); will set override_default_ip_site_link to "false", and the sequence $object->override_default_ip_site_link("false"); $object->default_ip_site_link('LAX'); will result in override_default_ip_site_link="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is a string with the default IP site link name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get default_ip_site_link value
my $default_ip_site_link = $ad_sites->default_ip_site_link();
#Modify default_ip_site_link value
$ad sites  default ip site link
```

```
                ->                      ('Site1');
```

last_sync_ts( )

Use this method to retrieve a timestamp of the last LDAP synchronization attempt. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_sync_ts value
my $last_sync_ts = $ad_sites->last_sync_ts();
```

last_sync_detail( )

Use this method to retrieve a string containing details of the last LDAP synchronization attempt. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_sync_detail value
my $last_sync_detail = $ad_sites->last_sync_detail();
```

last_sync_status( )

Use this method to retrieve a string containing status of the last LDAP synchronization attempt. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'OK', 'WARNING' or 'ERROR'.

Example

```
#Get last_sync_status value
my $last_sync_status = $ad_sites->last_sync_status();
```

ldap_timeout( )

Use this method to set or retrieve an LDAP connection timeout interval in seconds for the Microsoft Server.

Setting this method to a defined value implicitly sets the override_ldap_timeout method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ldap_timeout attribute to "false".

Note that when ldap_timeout is set to a defined value and override_dldap_timeout is set to "false", the last operation takes precedence. Thus the sequence $object->ldap_timeout(10); $object->override_ldap_timeout("false"); will set override_ldap_timeout to "false", and the sequence $object->override_ldap_timeout("false"); $object->ldap_timeout(10); will result in override_ldap_timeout="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ldap_timeout value
my $ldap_timeout = $ad_sites->ldap_timeout();
#Modify ldap_timeout value
$ad_sites->ldap_timeout(10);
```

ldap_auth_port( )

Use this method to set or retrieve an LDAP TCP connection port for the Microsoft Server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are unsinged integers between 0 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ldap_auth_port value
my $ldap_auth_port = $ad_sites->ldap_auth_port();
#Modify ldap_auth_port value
$ad_sites->ldap_auth_port(636);
```

ldap_encryption( )

Use this method to set or retrieve an encryption for the LDAP connection for the Microsoft Server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is 'SSL' or 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ldap_encryption value
my $ldap_encryption = $ad_sites->ldap_encryption();
#Modify ldap_encryption value
$ad_sites->ldap_encryption('SSL');
```

login_name( )

Use this method to set or retrieve the Microsoft Server login name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

When setting a value that requires a domain name, prepend the domain information followed by a backslash to the username: "domain\username".

Parameter

The valid value is a string that contains the login name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get login value
my $login = $ad_sites->login();
#Modify login value
$ad_sites->login("newuser");
```

login_password( )

Use this method to set a password for the Microsoft Server. This field is used only if the login field for this member is defined. This is a write-only attribute.

This field cannot be retrieved.

Parameter

The valid value is a string that contains the password.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set the password
$ad_sites->password("iG&ojG97Y");
```

managed( )

Use this method to set or retrieve the flag that indicates whether the sites of the Microsoft Server are to be synchronized with the assigned managing member or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get managed value
$managed = $ad_sites->managed();
#Modify managed value
$ad_sites->managed("true");
```

override_default_ip_site_link( )

The override_default_ip_site_link attribute controls whether the default_ip_site_link method values of the Microsoft Server are used, instead of the Grid default.

The override_default_ip_site_link attribute can be specified explicitly. It is also set implicitly when default_ip_site_link is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for default_ip_site_link. Set the parameter to "false" to inherit the Grid-level setting for default_ip_site_link. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_default_ip_site_link
my $override_default_ip_site_link = $ad_sites->override_default_ip_site_link();
#Modify override_default_ip_site_link
$ad_sites->override_default_ip_site_link("true");
```

override_login( )

The override_login attribute controls whether the login_name method values of the Microsoft Server are used, instead of the Grid default.

The override_login attribute can be specified explicitly. It is also set implicitly when login_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for login_name. Set the parameter to "false" to inherit the Grid-level setting for login_name. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_login
my $override_login = $ad_sites->override_login();
#Modify override_login
$ad_sites->override_login("true");
```

override_ldap_timeout( )

The override_ldap_timeout attribute controls whether the ldap_timeout method values of the Microsoft Server are used, instead of the Grid default.

The override_ldap_timeout attribute can be specified explicitly. It is also set implicitly when ldap_timeout is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for ldap_timeout. Set the parameter to "false" to inherit the Grid-level setting for ldap_timeout. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ldap_timeout
my $override_ldap_timeout = $ad_sites->override_ldap_timeout();
#Modify override_ldap_timeout
$ad_sites->override_ldap_timeout("true");
```

override_synchronization_interval( )

The override_synchronization_interval attribute controls whether the synchronization_interval method values of the Microsoft Server are used, instead of the Grid default.

The override_synchronization_interval attribute can be specified explicitly. It is also set implicitly when synchronization_interval is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for synchronization_interval. Set the parameter to "false" to inherit the Grid-level setting for synchronization_interval. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_synchronization_interval
my $override_synchronization_interval = $ad_sites->override_synchronization_interval();
#Modify override_synchronization_interval
$ad_sites->override_synchronization_interval("true");
```

read_only( )

Use this method to enable or disable read-only synchronization of the sites for the Active Directory Domain.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get read_only value
$read_only = $ad_sites->read_only();
#Modify read_only value
$ad_sites->read_only("true");
```

synchronization_interval( )

Use this method to set or retrieve the synchronization interval of the sites for the Active Directory Domain.

Setting this method to a defined value implicitly sets the override_synchronization_interval method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_synchronization_interval attribute to "false".

Note that when synchronization_interval is set to a defined value and override_dsynchronization_interval is set to "false", the last operation takes precedence. Thus the sequence $object->synchronization_interval(10); $object->override_synchronization_interval("false"); will set override_synchronization_interval to "false", and the sequence $object->override_synchronization_interval("false"); $object->synchronization_interval(10); will result in override_synchronization_interval="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get synchronization_interval value
my $synchronization_interval = $ad_sites->synchronization_interval();
#Modify synchronization_interval value
$ad_sites->synchronization_interval(10);
```

NAME

Infoblox::Grid::MSServer::AdSites::Domain - the Active Directory Domain object.

DESCRIPTION

The object provides information about the Active Directory Domain.

SESSION METHODS

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

  name          - Optional. The Active Directory Domain name in DNS form.
  netbios       - Optional. The Active Directory Domain name in NetBIOS form.
  network_view   - Optional. The network view which the Active Directory Domain is associated with.
  ea_definition - Optional. Extensible attribute definition that is linked with this Active
Directory Domain.
```

Example

```
my @retrieved_objs = $session->get(
   name          => 'domain.com',
   netbios       => 'DOMAIN',
   network_view  => 'external',
   ea_definition => 'DOMAIN.external Site',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

  ea_definition - Optional. Extensible attribute definition that is linked with this Active
Directory Domain.
  name          - Optional. The Active Directory Domain name in DNS form.
  netbios       - Optional. The Active Directory Domain name in NetBIOS form.
  network_view   - Optional. The network view which the Active Directory Domain is associated with.
```

Example

```
my @retrieved_objs = $session->search(
   netbios => 'DOMAIN*',
);
```

METHODS

ms_sync_master_name( )

Use this method to retrieve IP address or FQDN of the managing master Microsoft Server. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get ms_sync_master_name value
my $sync_master_name = $domain->ms_sync_master_name();
```

ea_definition( )

Use this method to retrieve extensible attribute definition that is linked with the Active Directory Domain. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get ea_definition value
my $ea_definition = $domain->ea_definition();
```

network_view( )

Use this method to retrieve the network view which the Active Directory Domain is associated with. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get network_view value
my $network_view = $domain->network_view();
```

netbios( )

Use this method to retrieve the Active Directory Domain name in NetBIOS form. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get netbios value
my $netbios = $domain->netbios();
```

name( )

Use this method to retrieve the Active Directory Domain name in DNS form. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get name value
my $name = $domain->name();
```

read_only( )

Use this method to retrieve the flag that indicates if this Active Directory Domain is synchronized in Read-Only or Read/Write mode. This is a read-only attribute.

Parameter

None

Returns

The valid return value is "true" or "false".

Example

```
#Get read_only value
my $read_only = $domain->read_only();
```

NAME

Infoblox::Grid::MSServer::AdSites::Site - object that represents Active Directory Site.

DESCRIPTION

The object provides information about Active Directory Site.

CONSTRUCTOR

```
my $ms_adsite = Infoblox::Grid::MSServer::AdSites::Site->new(
   domain   => $adsites_domain,                #Required
   name     => $string,                        #Required
   networks => [$network1, $network2, ...],    #Optional / Default is undefined
);
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to the Active Directory Site.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
my $site = Infoblox::Grid::MSServer::AdSites::Site->new(
    domain   => $domain,
    name     => 'Site0',
    networks => [$network1, $network2],
);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
my $site = $session->get(
    domain => $domain,
    name   => 'Site0',
);

$session->remove($site);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

Apply the following attribute to get a specific object:

```
   name   - Optional. The Active Directory Site name.
   domain - Optional. An Infoblox::Grid::MSServer::AdSites::Domain object.
```

Example

```
my @retrieved_objs = $session->get(
   name   => 'Site0',
   domain => $domain,
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
$site->name('Site2');
$session->modify($site);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

  name   - Optional. The Active Directory Site name.
  domain - Optional. An Infoblox::Grid::MSServer::AdSites::Domain object.
```

Example

```
my @retrieved_objs = $session->search(
   name   => 'Site*',
);
```

METHODS

domain( )

Use this method to retrieve Active Directory Domain to which this Active Directory belongs.

Note that you can create a Site object with a given Active Directory Domain but once you've created, you will not be able modify a Domain of existing objects.

Parameter

Valid value is an Infoblox::Grid::MSServer::AdSites::Domain object.

Returns

The method returns the attribute value.

Example

```
#Get domain value
my $domain = $site->domain();
```

move_subnets( )

Use this method to move subnets beetween Active Directory Domain Sites.

Parameters

```
 networks - a list of Infoblox::DHCP::Network and Infoblox::DHCP::IPv6Network objects to perform the
move operation on.
```

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#move subnets to the site
$site->move_subnets(
   networks => [$network1, $network2],
);
```

name( )

Use this method to set or retrieve the Active Directory Site name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a string that contains the Active Directory Site name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $site->name();
#Modify name value
$site->name('Site1');
```

networks( )

Use this method to set or retrieve the list of networks associated with this Active Directory Site.

Parameter

The valid value is a list of Infoblox::DHCP::Network, Infoblox::DHCP::NetworkContainer, Infoblox::DHCP::IPv6Network and Infoblox::DHCP::IPv6NetworkContainer objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get networks value
my @networks = $site->networks();
#Modify networks value
$site->networks([$network1, $network2, $network3]);
```

NAME

Infoblox::Grid::MSServer::AdUser - the Active Directory User object.

DESCRIPTION

The object provides information about synchronization of the Active Directory users.

CONSTRUCTOR

```
my $ad_user = Infoblox::Grid::MSServer::AdUser->new(
   enable_user_sync                => "true" | "false", # Optional / Default is 'true'
   login_name                      => $string,          # Optional / Default is undefined
   login_password                  => $string,          # Optional / Default is undefined
   synchronization_interval        => $uint,            # Optional / Default is undefined
   override_login                  => "true" | "false", # Optional / Default is 'false'
   override_enable_user_sync       => "true" | "false", # Optional / Default is 'false'
   override_synchronization_interval => "true" | "false", # Optional / Default is 'false'
```

SESSION METHODS

The object does not support any session methods. It is retrieved as a part of the Microsoft Server object.

MODULE METHODS

The following functions can be applied to a Active Directory User object.

Infoblox::Grid::MSServer->ad_user( )

Use this method to set or retrieve structure containing Active Directory User synchronization information. See Infoblox::Grid::MSServer->ad_user() for parameters and return values.

Example

```
#Get ad_user value
my $ad_user = $msserver->ad_user();
#Modify ad_user value
my $res = $msserver->ad_user($ad_user);
```

METHODS

this section describes all the methods that you can use to set or retrieve the attribute values of the object.

enable_user_sync( )

Use this method to enable or disable the Active Directory user information synchronization.

Setting this method to a defined value implicitly sets the override_enable_user_sync method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_enable_user_sync method to "false".

Note that when enable_user_sync is set to a defined value and override_enable_user_sync is set to "false", the last operation takes precedence. Thus the sequence $object->enable_user_sync("true"); $object->override_enable_user_sync("false"); will set override_enable_user_sync to "false", and the sequence $object->override_enable_user_sync("false"); $object->enable_user_sync("true"); will result in override_enable_user_sync="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable Active Directory user information synchronization or "false" to forbid it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_user_sync value
my $enable_user_sync = $ad_user->enable_user_sync();
#Modify enable_user_sync value
$ad_user->enable_user_sync("true");
```

last_sync_time( )

Use this method to retrieve the timestamp of the last Active Directory user information synchronization attempt. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_sync_time value
my $last_sync_time = $ad_user->last_sync_time();
```

last_sync_detail( )

Use this method to retrieve a string containing details of the last Active Directory user information synchronization attempt. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_sync_detail value
my $last_sync_detail = $ad_user->last_sync_detail();
```

last_sync_status( )

Use this method to retrieve a string containing status of the last Active Directory user information synchronization attempt. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'OK', 'WARNING' or 'ERROR'.

Example

```
#Get last_sync_status value
my $last_sync_status = $ad_user->last_sync_status();
```

login_name( )

Use this method to set or retrieve the Active Directory user login name.

Setting this method to a defined value implicitly sets the override_login method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_login attribute to "false".

Note that when login_name is set to a defined value and override_dlogin_name is set to "false", the last operation takes precedence. Thus the sequence $object->login_name('newuser'); $object->override_login("false"); will set override_login to "false", and the sequence $object->override_login("false"); $object->login_name('newuser'); will result in override_login="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

When setting a value that requires a domain name, prepend the domain information followed by a backslash to the username: "domain\username".

Parameter

The valid value is a string that contains the login name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get login value
my $login = $ad_user->login_name();
#Modify login value
$ad_user->login_name("newuser");
```

login_password( )

Use this method to set a password for the Active Directory user. This field is used only if the login field for this member is defined. This is a write-only attribute.

This field cannot be retrieved.

Parameter

The valid value is a string that contains the password.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set the password
$ad_user->login_password("iG&ojG97Y");
```

override_enable_user_sync( )

The override_enable_user_sync attribute controls whether the enable_user_sync method values of the Active Directory user are used, instead of the Grid default.

The override_enable_user_sync attribute can be specified explicitly. It is also set implicitly when enable_user_sync is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for enable_user_sync. Set the parameter to "false" to inherit the Grid-level setting for enable_user_sync. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_user_sync
my $override_enable_user_sync = $ad_user->override_enable_user_sync();
#Modify override_enable_user_sync
$ad_user->override_enable_user_sync("true");
```

override_login( )

The override_login attribute controls whether the login_name method values of the Active Directory user are used, instead of the Grid default.

The override_login attribute can be specified explicitly. It is also set implicitly when login_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for login_name. Set the parameter to "false" to inherit the Grid-level setting for login_name. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_login
my $override_login = $ad_user->override_login();
#Modify override_login
$ad_user->override_login("true");
```

override_synchronization_interval( )

The override_synchronization_interval attribute controls whether the synchronization_interval method values of the Active Directory user are used, instead of the Grid default.

The override_synchronization_interval attribute can be specified explicitly. It is also set implicitly when synchronization_interval is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for synchronization_interval. Set the parameter to "false" to inherit the Grid-level setting for synchronization_interval. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_synchronization_interval
my $override_synchronization_interval = $ad_user->override_synchronization_interval();
#Modify override_synchronization_interval
$ad_user->override_synchronization_interval("true");
```

synchronization_interval( )

Use this method to set or retrieve the synchronization interval of the Active Directory user.

Setting this method to a defined value implicitly sets the override_synchronization_interval method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_synchronization_interval attribute to "false".

Note that when synchronization_interval is set to a defined value and override_dsynchronization_interval is set to "false", the last operation takes precedence. Thus the sequence $object->synchronization_interval(10); $object->override_synchronization_interval("false"); will set override_synchronization_interval to "false", and the sequence $object->override_synchronization_interval("false"); $object->synchronization_interval(10); will result in override_synchronization_interval="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get synchronization_interval value
my $synchronization_interval = $ad_user->synchronization_interval();
#Modify synchronization_interval value
$ad_user->synchronization_interval(10);
```

NAME

Infoblox::Grid::MSServer::AdUser::Data - the Active Directory User Data object.

DESCRIPTION

The object provides information about the Active Directory users.

SESSION METHODS

The object does not support any session methods. It is retrieved as a part of the following objects: Infoblox::IPAM::Address, Infoblox::IPAM::Statistics, Infoblox::DHCP::Network, Infoblox::DHCP::SharedNetwork, Infoblox::DHCP::Range, Infoblox::DHCP::FixedAddr, Infoblox::DHCP::IPv6FixedAddr, Infoblox::DHCP::HostAddr, Infoblox::DNS::Host, Infoblox::DNS::Record::A, Infoblox::DNS::Record::AAAA, Infoblox::DNS::Record::PTR, Infoblox::Grid::Discovery::Device, Infoblox::Grid::CloudAPI::VMAddress.

METHODS

this section describes all the methods that you can use to set or retrieve the attribute values of the object.

active_users_count( )

Use this method to retrieve the number of active users. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an unsigned integer.

Example

```
#get active_users_count
my $active_users_count = $data->active_users_count();
```

NAME

Infoblox::Grid::MSServer::DCNSRecordCreation - An Infoblox Active Directory Domain Controller object

---

DESCRIPTION

The Active Directory Domain Controller object represents the Active Directory Domain Controller which is allowed for NS Record creation in a DNS Zone.

CONSTRUCTOR

```
my $dcncrecordcreation = Infoblox::Grid::MSServer::DCNSRecordCreation->new(
    address => $ipv4addr | $ipv6addr, #Required
    comment => $string,               #Optional / Default is undefined
);
```

SESSION METHODS

The object does not support any session methods. It is retrieved as a part of the DNS Zone object. It also can be retrieved as a result of Infoblox::Session->get_ms_dc_ns_record_creation_list() function.

MODULE METHODS

The following functions can be applied to a AD Domain Controller object.

Infoblox::DNS::Zone->ms_dc_ns_record_creation( )

Use this method to set or retrieve the list of Active Directory Domain Controllers which are allowed to create NS Record for the DNS Zone. See Infoblox::DNS::Zone->ms_dc_ns_record_creation() for parameters and return values.

Example

```
#Get ms_dc_ns_record_creation
my $ms_dc_ns_record_creation = $zone->ms_dc_ns_record_creation();

#Modify ms_dc_ns_record_creation
$zone->ms_dc_ns_record_creation([$msdcns1, $msdcns1]);
```

METHODS

this section describes all the methods that you can use to set or retrieve the attribute values of the object.

address( )

Use this method to set or retrieve the address of a Domain Controller.

Parameter

The valid value is a desired IPv4 or IPv6 address in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address value
my $address = $object->address();

#Set address value
$object->address('10.0.0.1');
```

comment( )

Use this method to set or retrieve the descriptive comment.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $address = $object->comment();

#Set comment value
$object->comment('desired-comment');
```

NAME

Infoblox::Grid::MSServer::DHCP - Grid Microsoft (r) Server DHCP object.

DESCRIPTION

You can use Infoblox::Grid::MSServer::DHCP to configure some of the DHCP properties of a Microsoft DHCP server, including enabling/disabling the DHCP service. The service configurations of a grid are not inherited by this object.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a Microsoft Server DHCP object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
 Apply the following attributes to get a specific grid member object:

  address - Required. A Microsoft server address or name in FQDN (Fully Qualified Domain Name)
format.
```

Example

```
my @retrieved_objs = $session->get(
    object  => "Infoblox::Grid::MSServer::DHCP",
    address => "10.0.0.1");
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific grid member object:

  address - Required. A Microsoft server address or name in FQDN (Fully Qualified Domain Name)
format. (Regular expressions are supported)
```

Example

```
my @retrieved_objs = $session->search(
    object  => "Infoblox::Grid::MSServer::DHCP",
    address => "domain.*");
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify a field of a grid Microsoft DHCP server.
$grid_msserver_dhcp->enable_dhcp('true');
# Submit modification
my $response = $session->modify( $grid_msserver_dhcp );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a grid Microsoft DHCP server.

manage_dhcp()

Retrieve or set the managed state of the Microsoft DHCP server. When setting the managed state, use true to enable or false to disable synchronization of the DHCP server. Setting the status does not stop or start the actual DHCP server, but controls whether it is synchronized.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get manage_dhcp
my $manage_dhcp = $msserver_dhcp->manage_dhcp();
#Modify manage_dhcp
$msserver_dhcp->manage_dhcp("true");
```

enable_dhcp()

Set the DHCP service status of the Microsoft DHCP server. When setting the service status, use true to enable or false to disable the DHCP service on the Microsoft DHCP server. Setting the service status stops or starts the actual DHCP service. This only applies if `manage_dhcp()` is true.

When setting the service status, the Microsoft DHCP server will be started or stopped at the next synchronization.

Include the specified parameter to set the attribute value. This setting is write-only. To get the actual status of the service, use the `status()` method.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp
my $enable_dhcp = $msserver_dhcp->enable_dhcp();
#Modify enable_dhcp
$msserver_dhcp->enable_dhcp("true");
```

status()

Retrieve the running status of the DHCP service of the Microsoft DHCP server. The running status is "running", "stopped", or "error". The returned status is the latest known status as of the date returned by the `status_last_updated()` attribute.

Returns

The method returns the attribute value.

Example

```
#Get status
my $status = $msserver_dhcp->status();
```

status_detail()

Retrieve the detailed running status of the DHCP service of the Microsoft DHCP server. The returned status is the latest known status.

Returns

The method returns the attribute value.

Example

```
#Get status
my $status = $msserver_dhcp->status();
```

status_last_updated()

Retrieve the time when the DHCP service status of the Microsoft DHCP server was last updated.

Returns

The method returns the attribute value.

Example

```
#Get status_last_updated
my $status_last_updated = $msserver_dhcp->status_last_updated();
```

last_sync_ts()

Retrieve the timestamp of the end of the last synchronization attempt related to all DHCP data, except leases.

Returns

The method returns the attribute value.

Example

```
#Get last_sync_ts
my $last_sync_ts = $msserver_dhcp->last_sync_ts();
```

last_sync_status()

Retrieve the result of the last synchronization attempt, if last_sync_ts is defined. Valid values are "Ok", "Warning", or "Error".

Returns

The method returns the attribute value.

Example

```
#Get last_sync_status
my $last_sync_status = $msserver_dhcp->last_sync_status();
```

last_sync_detail()

Retrieve the detailed result of the last synchronization attempt, if last_sync_ts is defined.

Returns

The method returns the attribute value.

Example

```
#Get last_sync_detail
my $last_sync_detail = $msserver_dhcp->last_sync_detail();
```

login_name( )

Use this method to set or retrieve the Microsoft Server DHCP login name.

Setting this method to a defined value implicitly sets the override_login method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_login attribute to "false".

Note that when login_name is set to a defined value and override_dlogin_name is set to "false", the last operation takes precedence. Thus the sequence $object->login_name('newuser'); $object->override_login("false"); will set override_login to "false", and the sequence $object->override_login("false"); $object->login_name('newuser'); will result in override_login="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

When setting a value that requires a domain name, prepend the domain information followed by a backslash to the username: "domain\username".

Parameter

The valid value is a string that contains the login name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get login value
my $login = $msserver_dhcp->login_name();
#Modify login value
$msserver_dhcp->login_name("newuser");
```

login_password( )

Use this method to set a password for the Microsoft Server DHCP. This field is used only if the login field for this member is defined. This is a write-only attribute.

This field cannot be retrieved.

Parameter

The valid value is a string that contains the password.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set the password
$msserver_dhcp->login_password("iG&ojG97Y");
```

extattrs( )

Use this method to retrieve the extensible attributes associated with a Grid Microsoft DHCP Server object. This attribute is read-only and cannot be set.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $msserver_dhcp->extattrs();
```

extensible_attributes()

Use this method to retrieve the extensible attributes of the associated Grid Microsoft DHCP Server object.

This method is read-only. Use the Infoblox::Grid::MSServer object to set or modify the extensible attributes of the Grid Microsoft DHCP Server object.

Returns

The method returns the attribute value.

Example

```
#Get extensible_attributes
my $extensible_attributes = $msserver_dhcp->extensible_attributes();
```

address()

Use this method to retrieve the IP address or FQDN of the associated Grid Microsoft DHCP Server object.

This method is read-only. Use the Infoblox::Grid::MSServer object to set or modify the Grid Microsoft DHCP Server object address.

Returns

The method returns the attribute value.

Example

```
#Get address
my $address = $msserver_dhcp->address();
```

broadcast_address()

Use this method to set or retrieve the broadcast address of the associated Grid Microsoft DHCP Server object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Returns

The Microsoft DHCP server broadcast address in IPV4 format.

Example

```
#Get address
my $address = $msserver_dhcp->broadcast_address();
#Modify broadcast_address
$msserver_dhcp->broadcast_address("10.0.0.1");
```

enable_ddns()

Retrieve or set the dynamic DNS flag of the Microsoft DHCP server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ddns
my $enable_ddns = $msserver_dhcp->enable_ddns();
#Modify enable_ddns
$msserver_dhcp->enable_ddns("true");
```

enable_invalid_mac( )

Use this method to allow invalid MAC address synchronization in DHCP leases and fixed addresses.

Setting this method to a defined value implicitly sets the override_enable_invalid_mac method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_enable_invalid_mac method to "false".

Note that when enable_invalid_mac is set to a defined value and override_enable_invalid_mac is set to "false", the last operation takes precedence. Thus the sequence $object->enable_invalid_mac("true"); $object->override_enable_invalid_mac("false"); will set override_enable_invalid_mac to "false", and the sequence $object->override_enable_invalid_mac("false"); $object->enable_invalid_mac("true"); will result in override_enable_invalid_mac="true".

Parameter

Specify "true" to allow invalid MAC address synchronization or "false" to forbid it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_invalid_mac value
my $enable_invalid_mac = $msserver_dhcp->enable_invalid_mac();
#Modify enable_invalid_mac value
$msserver_dhcp->enable_invalid_mac("true");
```

enable_monitoring( )

Use this method to enable or disable the monitoring and control of DHCP service.

Setting this method to a defined value implicitly sets the override_enable_monitoring method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_enable_monitoring method to "false".

Note that when enable_monitoring is set to a defined value and override_enable_monitoring is set to "false", the last operation takes precedence. Thus the sequence $object->enable_monitoring("true"); $object->override_enable_monitoring("false"); will set override_enable_monitoring to "false", and the sequence $object->override_enable_monitoring("false"); $object->enable_monitoring("true"); will result in override_enable_monitoring="true".

Parameter

Specify "true" to allow invalid mac address synchronization or "false" to forbid it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_monitoring value
my $enable_monitoring = $msserver_dhcp->enable_dhcp_monitoring();
#Modify enable_monitoring value
$msserver_dhcp->enable_monitoring("true");
```

ddns_server_always_updates()

Retrieve or set the "Always update DDNS" flag of the Microsoft DHCP server. Use "true" to always allow dynamic DNS updates, or use "false" to only update when requested by the client. The default value is "false".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_server_always_updates
my $ddns_server_always_updates = $msserver_dhcp->ddns_server_always_updates();
#Modify ddns_server_always_updates
$msserver_dhcp->ddns_server_always_updates("true");
```

ms_options( )

Use this method to set or retrieve the custom DHCP options that are associated with the specified Microsoft DHCP server.

Note: You can set only options that are included in both the Microsoft server and NIOS predefined option definitions. Options that are not common to both are read-only and cannot be modified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains defined Infoblox::DHCP::MSOption objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $ref_options = $msserver_dhcp->ms_options();
#Modify options
$msserver_dhcp->ms_options([$option12]); #$option12 is an Infoblox::DHCP::MSOption object
```

comment()

Use this method to retrieve the comment associated with the Grid Microsoft DHCP Server object.

This method is read-only. Use the Infoblox::Grid::MSServer object to set or modify the Grid Microsoft DHCP Server object comment.

Returns

The method returns the attribute value.

Example

```
#Get comment
my $comment = $msserver_dhcp->comment();
```

read_only()

Use this method to retrieve the read_only flag of the associated Grid Microsoft DHCP Server object.

This method is read-only. Use the Infoblox::Grid::MSServer object to set or modify the Grid Microsoft DHCP Server object read_only status.

Returns

The method returns the attribute value.

Example

```
#Get read_only
my $read_only = $msserver_dhcp->read_only();
```

name()

Use this method to retrieve the name of the associated Grid Microsoft DHCP Server object.

This method is read-only. Use the Infoblox::Grid::MSServer object to set or modify the Grid Microsoft DHCP Server object name.

Returns

The method returns the attribute value.

Example

```
#Get name
my $name = $msserver_dhcp->name();
```

static_hosts()

Use this method to retrieve the number of static addresses (fixed addresses and reservations) associated with the Microsoft server.

Returns

The method returns the attribute value.

Example

```
#Get static_hosts
my $static_hosts = $msserver_dhcp->static_hosts();
```

supports_failover( )

Use this method to retrieve the flag used to indicate whether DHCP supports failover. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get supports_failover value
my $supports_failover = msserver_dhcp->supports_failover();
```

dynamic_hosts()

Use this method to retrieve the number of active leases associated with the Microsoft server.

Returns

The method returns the attribute value.

Example

```
#Get dynamic_hosts
my $dynamic_hosts = $msserver_dhcp->dynamic_hosts();
```

dhcp_utilization()

Use this method to retrieve the DHCP utilization status of the Microsoft server. The returned value is between 0 and 1000. 1000 indicates 100% utilization.

Returns

The method returns the attribute value.

Example

```
#Get dhcp_utilization
my $dhcp_utilization = $msserver_dhcp->dhcp_utilization();
```

dhcp_utilization_status()

Use this method to retrieve the DHCP utilization status of the Microsoft server. The returned value is 'Low', 'Normal', 'High', or 'Full', and depend on the value of the low- and high-water mark parameters.

Returns

The method returns the attribute value.

Example

```
#Get dhcp_utilization_status
my $dhcp_utilization_status = $msserver_dhcp->dhcp_utilization_status();
```

override_enable_invalid_mac( )

The override_enable_invalid_mac attribute controls whether the enable_invalid_mac method values of the Microsoft Server DHCP object are used, instead of the Grid default.

The override_enable_invalid_mac attribute can be specified explicitly. It is also set implicitly when enable_invalid_mac is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_invalid_mac. Set the parameter to "false" to inherit the

grid-level setting for enable_invalid_mac. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_invalid_mac
my $override_enable_invalid_mac = $msserver_dhcp->override_enable_invalid_mac();
#Modify override_enable_invalid_mac
$msserver_dhcp->override_enable_invalid_mac("true");
```

override_enable_monitoring( )

The override_enable_monitoring attribute controls whether the enable_monitoring method values of the Microsoft Server DHCP object are used, instead of the Grid default.

The override_enable_monitoring attribute can be specified explicitly. It is also set implicitly when enable_monitoring is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_monitoring. Set the parameter to "false" to inherit the grid-level setting for enable_monitoring. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_monitoring
my $override_enable_monitoring = $msserver_dhcp->override_enable_monitoring();
#Modify override_enable_monitoring
$msserver_dhcp->override_enable_monitoring("true");
```

override_login( )

The override_login attribute controls whether the login_name method values of the Microsoft Server DHCP are used, instead of the Grid default.

The override_login attribute can be specified explicitly. It is also set implicitly when login_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for login_name. Set the parameter to "false" to inherit the Grid-level setting for login_name. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_login
my $override_login = $msserver_dhcp->override_login();
#Modify override_login
$msserver_dhcp->override_login("true");
```

override_synchronization_interval( )

The override_synchronization_interval attribute controls whether the synchronization_interval method values of the Microsoft Server DHCP are used, instead of the Grid default.

The override_synchronization_interval attribute can be specified explicitly. It is also set implicitly when synchronization_interval is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for synchronization_interval. Set the parameter to "false" to inherit the Grid-level setting for synchronization_interval. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_synchronization_interval
my $override_synchronization_interval = $msserver_dhcp->override_synchronization_interval();
#Modify override_synchronization_interval
$msserver_dhcp->override_synchronization_interval("true");
```

synchronization_interval( )

Use this method to set or retrieve the synchronization interval of the Microsoft Server DHCP.

Setting this method to a defined value implicitly sets the override_synchronization_interval method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_synchronization_interval attribute to "false".

Note that when synchronization_interval is set to a defined value and override_dsynchronization_interval is set to "false", the last operation takes precedence. Thus the sequence $object->synchronization_interval(10); $object->override_synchronization_interval("false"); will set override_synchronization_interval to "false", and the sequence $object->override_synchronization_interval("false"); $object->synchronization_interval(10); will result in override_synchronization_interval="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get synchronization_interval value
my $synchronization_interval = $msserver_dhcp->synchronization_interval();
#Modify synchronization_interval value
$msserver_dhcp->synchronization_interval(10);
```

NAME

Infoblox::Grid::MSServer::DNS - Grid Microsoft (r) Server DNS object.

DESCRIPTION

A Grid Microsoft Server DNS object is a single Microsoft DNS server managed by a Grid member.

You can use Infoblox::Grid::MSServer::DNS to configure some of the DNS properties of a Microsoft DNS server, including enabling/disabling the DNS service. The service configurations of a Grid are not inherited by this object.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a Microsoft Server DNS object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid member object:

 address     - Optional. A member address or name in FQDN (Fully Qualified Domain Name) format.
 server_ip   - Optional. A member address.
 server_name - Optional. A member name in FQDN (Fully Qualified Domain Name) format.
```

Example

```
my @retrieved_objs = $session->get(
    object    => "Infoblox::Grid::MSServer::DNS",
    server_ip => "10.0.0.1");
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment of a Grid Microsoft DNS server.
$grid_msserver_dns->enable_dns('true');
# Submit modification
my $response = $session->modify( $grid_msserver_dns );
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific Grid member object:

 server_ip   - Required. A member address.
 server_name - Optional. A member name in FQDN (Fully Qualified Domain Name) format.
```

Example

```
my @retrieved_objs = $session->search(
    object      => "Infoblox::Grid::MSServer::DNS",
    server_name => "domain.*");
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Grid Microsoft DNS server.

manage_dns()

Retrieve or set the managed state of the Microsoft DNS server. When setting the managed state, use true to enable or false to disable synchronization of the DNS server. Setting the status does not stop or start the actual DNS server but controls whether it is synchronized.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get manage_dns
my $manage_dns = $msserver_dns->manage_dns();
#Modify manage_dns
$msserver_dns->manage_dns("true");
```

enable_dns()

Set the DNS service status of the Microsoft DNS server. When setting the service status, use true to enable or false to disable the DNS service on the Microsoft DNS server. Setting the service status stops or starts the actual DNS service. This only applies if `manage_dns()` is true.

When setting the service status, the Microsoft DNS server will be started or stopped at the next synchronization.

Include the specified parameter to set the attribute value. This setting is read-only. To get the actual status of the service, use the `status()` method.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dns
my $enable_dns = $msserver_dns->enable_dns();
#Modify enable_dns
$msserver_dns->enable_dns("true");
```

enable_dns_reports_sync( )

Use this method to enable or disable the synchronization of DNS reporting data for the Microsoft server.

Setting this method to a defined value implicitly sets the override_enable_dns_reports_data_sync method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_enable_dns_reports_sync method to "false".

Note that when enable_dns_reports_sync is set to a defined value and override_enable_dns_reports_sync is set to "false", the last operation takes precedence. Thus the sequence $object->enable_dns_reports_sync("false"); $object->override_enable_dns_reports_sync("false"); will set override_enable_dns_reports_sync to "false", and the sequence $object->override_enable_dns_reports_sync("false"); $object->enable_dns_reports_sync("false"); will result in override_enable_dns_reports_sync="true".

Parameter

Specify "true" to enable the synchronization of DNS reporting data from the Microsoft server. Specify "false" to disable the synchronization of DNS reporting data from the Microsoft server. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dns_reports_sync
my $enable_dns_reports_sync = $msserver_dns->enable_dns_reports_sync();
#Modify enable_dns_reports_sync
$msserver_dns->enable_dns_reports_sync("true");
```

enable_monitoring( )

Use this method to enable or disable the monitoring and control of DNS service on Microsoft Server.

Setting this method to a defined value implicitly sets the override_enable_monitoring method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_enable_monitoring method to "false".

Note that when enable_monitoring is set to a defined value and override_enable_monitoring is set to "false", the last operation takes precedence. Thus the sequence $object->enable_monitoring("true"); $object->override_enable_monitoring("false"); will set override_enable_monitoring to "false", and the sequence $object->override_enable_monitoring("false"); $object->enable_monitoring("true"); will result in override_enable_monitoring="true".

Parameter

Specify "true" to enable monitoring and control of DNS service on all Microsoft servers in the Grid and "false" to forbid it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_monitoring value
my $enable_monitoring = $msserver_dns->enable_monitoring();
#Modify enable_monitoring value
$msserver_dns->enable_monitoring("true");
```

login_name( )

Use this method to set or retrieve the Microsoft Server DNS login name.

Setting this method to a defined value implicitly sets the override_login method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_login attribute to "false".

Note that when login_name is set to a defined value and override_dlogin_name is set to "false", the last operation takes precedence. Thus the sequence $object->login_name('newuser'); $object->override_login("false"); will set override_login to "false", and the sequence $object->override_login("false"); $object->login_name('newuser'); will result in override_login="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

When setting a value that requires a domain name, prepend the domain information followed by a backslash to the username: "domain\username".

Parameter

The valid value is a string that contains the login name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get login value
my $login = $msserver_dns->login_name();
#Modify login value
$msserver_dns->login_name("newuser");
```

login_password( )

Use this method to set a password for the Microsoft Server DNS. This field is used only if the login field for this member is defined. This is a write-only attribute.

This field cannot be retrieved.

Parameter

The valid value is a string that contains the password.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set the password
$msserver_dns->login_password("iG&ojG97Y");
```

override_enable_dns_reports_sync( )

The override_enable_dns_reports_sync attribute controls whether the enable_dns_reports_sync method values of the Microsoft Server DNS object are used, instead of the Grid default.

The override_enable_dns_reports_sync attribute can be specified explicitly. It is also set implicitly when enable_dns_reports_sync is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for enable_dns_reports_sync. Set the parameter to "false" to inherit the Grid-level setting for enable_dns_reports_sync. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_dns_reports_sync
my $override_enable_dns_reports_sync = $msserver_dns->override_enable_dns_reports_sync();
#Modify override_enable_dns_reports_sync
$msserver_dns->override_enable_dns_reports_sync("true");
```

override_enable_monitoring( )

The override_enable_monitoring attribute controls whether the enable_monitoring method values of the Microsoft Server DNS object are used, instead of the Grid default.

The override_enable_monitoring attribute can be specified explicitly. It is also set implicitly when enable_monitoring is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for enable_monitoring. Set the parameter to "false" to inherit the Grid-level setting for enable_monitoring. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_monitoring
my $override_enable_monitoring = $msserver_dns->override_enable_monitoring();
#Modify override_enable_monitoring
$msserver_dns->override_enable_monitoring("true");
```

override_login( )

The override_login attribute controls whether the login_name method values of the Microsoft Server DNS are used, instead of the Grid default.

The override_login attribute can be specified explicitly. It is also set implicitly when login_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for login_name. Set the parameter to "false" to inherit the Grid-level setting for login_name. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_login
my $override_login = $msserver_dns->override_login();
#Modify override_login
$msserver_dns->override_login("true");
```

override_synchronization_interval( )

The override_synchronization_interval attribute controls whether the synchronization_interval method values of the Microsoft Server DNS are used, instead of the Grid default.

The override_synchronization_interval attribute can be specified explicitly. It is also set implicitly when synchronization_interval is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for synchronization_interval. Set the parameter to "false" to inherit the Grid-level setting for synchronization_interval. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_synchronization_interval
my $override_synchronization_interval = $msserver_dns->override_synchronization_interval();
#Modify override_synchronization_interval
$msserver_dns->override_synchronization_interval("true");
```

status()

Retrieve the running status of the DNS service of the Microsoft DNS server. Returns a status that is "running", "stopped", or "error". The returned status is the latest known status as of the date returned by the `status_last_updated()` attribute.

Returns

The method returns the attribute value.

Example

```
#Get status
my $status = $msserver_dns->status();
```

status_detail()

Retrieve the detailed running status of the DNS service of the Microsoft DNS server. The returned status is the latest known status.

Returns

The method returns the attribute value.

Example

```
#Get status
my $status = $msserver_dns->status();
```

status_last_updated()

Retrieve the time when the DNS service status of the Microsoft DNS server was last updated.

Returns

The method returns the attribute value.

Example

```
#Get status_last_updated
my $status_last_updated = $msserver_dns->status_last_updated();
```

synchronization_interval( )

Use this method to set or retrieve the synchronization interval of the Microsoft Server DNS.

Setting this method to a defined value implicitly sets the override_synchronization_interval method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_synchronization_interval attribute to "false".

Note that when synchronization_interval is set to a defined value and override_dsynchronization_interval is set to "false", the last operation takes precedence. Thus the sequence $object->synchronization_interval(10); $object->override_synchronization_interval("false"); will set override_synchronization_interval to "false", and the sequence $object->override_synchronization_interval("false"); $object->synchronization_interval(10); will result in override_synchronization_interval="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get synchronization_interval value
my $synchronization_interval = $msserver_dns->synchronization_interval();
#Modify synchronization_interval value
$msserver_dns->synchronization_interval(10);
```

last_sync_ts()

Retrieve the timestamp of the end of the last synchronization attempt related to zone list and DNS properties.

Returns

The method returns the attribute value.

Example

```
#Get last_sync_ts
```

```
my $last_sync_ts = $msserver_dns->last_sync_ts();
```

last_sync_status()

Retrieve the result of the last synchronization attempt, if last_sync_ts is defined. Valid values are "Ok", "Warning", or "Error".

Returns

The method returns the attribute value.

Example

```
#Get last_sync_status
my $last_sync_status = $msserver_dns->last_sync_status();
```

last_sync_detail()

Retrieve the detailed result of the last synchronization attempt, if last_sync_ts is defined.

Returns

The method returns the attribute value.

Example

```
#Get last_sync_detail
my $last_sync_detail = $msserver_dns->last_sync_detail();
```

extattrs( )

Use this method to retrieve the extensible attributes associated with a Grid Microsoft DNS Server object. This attribute is read-only and cannot be set.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $msserver_dns->extattrs();
```

extensible_attributes()

Use this method to retrieve the extensible attributes of the associated Grid Microsoft DNS Server object.

This method is read-only. Use the Infoblox::Grid::MSServer object to set or modify the extensible attributes of the Grid Microsoft DNS Server object.

Returns

The method returns the attribute value.

Example

```
#Get extensible_attributes
my $extensible_attributes = $msserver_dns->extensible_attributes();
```

address()

Use this method to retrieve the IP address or FQDN of the associated Grid Microsoft DNS Server object.

This method is read-only. Use the Infoblox::Grid::MSServer object to set or modify the IP address of the Grid Microsoft DNS Server object.

Returns

The method returns the attribute value.

Example

```
#Get address
my $address = $msserver_dns->address();
```

name()

Use this method to retrieve the FQDN of the associated Grid Microsoft DNS Server object.

This method is read-only. Use the Infoblox::Grid::MSServer object to set or modify the IP address of the Grid Microsoft DNS Server object.

Returns

The method returns the attribute value.

Example

```
#Get address
my $name = $msserver_dns->name();
```

forwarders()

Use this method to specify forwarders for the Microsoft DNS server. A forwarder is essentially a name server to which other name servers first send all of their off-site queries. The forwarder builds up a cache of information, avoiding the need for the other name servers to send queries off-site.

This setting is a per Microsoft DNS server setting. It doesn't override the Grid-level setting and the Grid-level setting does not apply if no value is defined for this Microsoft DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify an array of IPV4/IPV6 addresses to set the list of forwarders.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get forwarders
my $forwarders = $msserver_dns->forwarders();
#Modify forwarders
$msserver_dns->forwarders(['10.0.0.1','10.0.0.2']);
```

NAME

Infoblox::Grid::NamedACL - Named ACL object.

DESCRIPTION

Named ACL object represents a named list of access control entries.

CONSTRUCTOR

```
 my $nacl = Infoblox::Grid::NamedACL->new(
    'name'                  => $string,
# Required
    'comment'               => $string,
# Optional
    'access_list'           => [ $ipv4addr | $ipv4_subnet/prefix | $ipv6addr |
# Optional
                                 $ipv6_subnet/prefix | $TSIGKey | $NamedACL, ... ],
    'extattrs'              => { $string => $extattr, ... },
# Optional / Default is undefined
    'extensible_attributes' => { $string => $string | $num, $string => [ $string | $num, ... ], ... },
# Optional
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a Named ACL object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Named ACL object:

 name    - Optional. The name of Named ACL object.
 comment - Optional. The comment in string format.
 extattrs- Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->get(
   object => 'Infoblox::Grid::NamedACL',
   name   => 'nacl',
```

```
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to take effect. See Infoblox::Session->restart() method.

Example

```
# Use this method to modify comment of Named ACL object.
$nacl->comment('new comment');
# Submit modification
my $response = $session->modify( $nacl );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::NamedACL",
    name   => "nacl");
# Find the desired object from the retrieved list.
my $desired_nacl = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_nacl );
```

Infoblox::Session->search( )

Use this method to search for Named ACL objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for Named ACL objects:

 name    - Optional. The name of Named ACL object (regular expression).
 comment - Optional. The comment in string format (regular expression).
 extattrs- Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->search(
   object => 'Infoblox::Grid::NamedACL',
   name   => 'nacl',
);
```

MODULE METHODS

Retrieved Named ACL objects in an access list are considered 'partial' objects. See Infoblox::Session->fill_partial_object() for more information on how it can be converted to a 'full' API object.

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of Named ACL object.

access_list( )

Use this method to set or retrieve an access list of Named ACL object.

Parameter

The valid value is an array reference that contains IPv4/IPv6 addresses, networks, Infoblox::DNS::TSIGKey objects and/or Infoblox::Grid::NamedACL objects.

To deny queries from certain IP addresses and networks, add "!" as a prefix to the IP addresses and networks.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $nacl->access_list();
# Modify attribute value
$nacl->access_list(['10.0.0.1', $tsigkey, $nacl]);
```

comment( )

Use this method to set or retrieve a descriptive comment about Named ACL object.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $nacl->comment();
# Modify attribute value
$nacl->comment('modified comment');
```

exploded_access_list( )

Use this method to retrieve the exploded access list of the Named ACL object. This is a read-only attribute.

Parameter

None.

Returns

The method returns the attribute value.

The valid value is an array reference that contains IPv4/IPv6 addresses, networks and/or Infoblox::DNS::TSIGKey objects.

Example

```
# Get attribute value
my $value = $nacl->exploded_access_list();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Named ACL object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $nacl->extattrs();
#Modify extattrs
$nacl->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with Named ACL object.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $nacl->extensible_attributes();
# Modify attribute value
$nacl->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

name( )

Use this method to set or retrieve the name of the Named ACL object.

Parameter

The name of the Named ACL object in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $nacl->name();
# Modify attribute value
$nacl->name('new_nacl');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify, search and remove. This sample also includes error handling for the operations.

#Preparation prior to getting and modifying an object

```
use strict;
use Infoblox;

#refers to Infoblox Appliance IP address
my $host_ip = "192.168.1.2";

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an object

```
my $nacl = Infoblox::Grid::NamedACL->new(
    name          => "NACL",
    access_list   => ['10.0.0.1', '20.0.0.0/24'],
    comment       => "Script Generated",
    );
unless ($nacl) {
       die("Construct object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "The object created successfully\n";

#Adding the object to appliance through session
my $response = $session->add( $nacl );
```

```
unless ($response) {
    die("Add object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"The object was added successfully \n";
```

#Search for the object

```
 my @retrieved_objs = $session->search(
     object => "Infoblox::Grid::NamedACL",
     name   => ".*");
 my $object = $retrieved_objs[0];

 unless ($object) {
        die("Search the object failed: ",
                $session->status_code() . ":" . $session->status_detail());
 }
 print "Search the object found at least 1 matching entry\n";
```

#Get and modify the object

```
#Get the object through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::NamedACL",
    name   => "NACL"
    );
my $nacl = $retrieved_objs[0];

unless ($nacl) {
    die("Get the object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Retrieved the object successfully \n";

# Modify one of the attributes of selected object.

$nacl->comment("Modified object");

#Applying the changes
$session->modify($nacl)
   or die("Modify the object failed",
            $session->status_code() . ":" . $session->status_detail());
print"The object was modified successfully \n";
```

#Remove the object

```
#Get the object through session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::NamedACL",
    name   => "NACL"
    );
my $desired_nacl = $retrieved_objs[0];

unless ($desired_nacl) {
    die("Get the object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Retrieved the object successfully \n";

#Submit the object for removal
$session->remove( $desired_nacl )
    or die("Remove the object failed",
           $session->status_code() . ":" . $session->status_detail());
print"The object was removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::NatGroup - NAT Group object.

DESCRIPTION

NAT Groups are necessary if the Grid master is behind a NAT device and there memberies behind both side of the NAT device. Any member on the same side as the master go into the same NAT group as the master and use their interface address for Grid communication with each other. Grid members on the other side of that NAT device do not go into the same NAT group as the master and use master's NAT address for Grid communication.

CONSTRUCTOR

```
#Constructor for an NAT Group object
my $nat_group = Infoblox::Grid::NatGroup->new (
        name    => $string      #Required
        comment => $string      #Optional / Default is empty
    );
```

MODULE METHODS

The following functions are available to be applied to an NatGroup object

Infoblox::Grid->nat_group_list( )

Use this function to specify a NatGroup. See Infoblox::Grid->nat_group_list() for parameters and return values.

Example

```
# Retrieve the list of NatGroup objects from Grid object.
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid",
    name   => "Infoblox" );

my $Grid_obj = $retrieved_objs[0];

# construct a NatGroup object
my $nat_group = Infoblox::Grid::NatGroup->new (
        name => "my_nat_group",
        comment => "inside NAT device");

# Modify Nat Group list.
$Grid_obj->nat_group_list([$nat_group]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute value of a NatGroup.

comment( )

Use this method to set or retrieve the descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $nat_group->comment();
#Modify comment
$nat_group->comment("new comment");
```

name( )

Use this method to set or retrieve a NAT group name

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get NAT group name
my $nat_group_name = $nat_group->name();
#Modify NAT group name
$nat_group->name("new_group_name");
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to an object such as create, modify, and remove an object. This sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Add a NAT Group object

```
my @result_array = $session->get( "object" => "Infoblox::Grid", "name" => "Infoblox");
if( scalar( @result_array ) > 0 )
 {
        my $Grid_obj = $result_array[0];
        unless ($Grid_obj) {
                die("Get Grid object failed: ",
        $session->status_code() . ":" . $session->status_detail());
        }
         # construct a NatGroup object
         my $nat_group = Infoblox::Grid::NatGroup->new (
              name => "my_nat_group",
              comment => "inside NAT device");

         # Add Nat Group to Grid object.
         $Grid_obj->nat_group_list([$nat_group]);
```

```
          $session->modify($Grid_obj);
          print "NAT Group added to Grid object sucessfully\n";
           }
```

#Modify existing NAT Group object

```
 @result_array = $session->get( "object" => "Infoblox::Grid", "name" => "Infoblox");
 if( scalar( @result_array ) > 0 )
  {
         my $Grid_obj = $result_array[0];
         unless ($Grid_obj) {
                 die("Get Grid object failed: ",
         $session->status_code() . ":" . $session->status_detail());
         }

          # get Nat Group from Grid object.
          my $nat_groups_list = $Grid_obj->nat_group_list();
          my $nat_group = @{$nat_groups_list}[0];

          #modify the NAT group name
          $nat_group->name("new_nat_group_name");

          # Add Nat Group to Grid object.
          $Grid_obj->nat_group_list([$nat_group]);

          $session->modify($Grid_obj);
          print "NAT Group modified on Grid object sucessfully\n";
           }
```

#Remove existing NAT Group object

```
 @result_array = $session->get( "object" => "Infoblox::Grid", "name" => "Infoblox");
 if( scalar( @result_array ) > 0 )
  {
         my $Grid_obj = $result_array[0];
         unless ($Grid_obj) {
                 die("Get Grid object failed: ",
         $session->status_code() . ":" . $session->status_detail());
         }

          # empty Nat Group list on Grid object.
          $Grid_obj->nat_group_list([]);

          $session->modify($Grid_obj);
          print "NAT Group removed on Grid object sucessfully\n";
           }

NAME

Infoblox::Grid::NTPAccess - Grid Network Time Protocol (NTP) access object.

DESCRIPTION

The Grid NTP access object is used to specify the access list for the NTP service.

CONSTRUCTOR

```
#Constructor for an Grid NTP access object
 my $ntp_access = Infoblox::Grid::NTPAccess->new(
    address         =>  $ipv4addr | "Any"   #Required
    service         => "Time" | "Time and NTP control"          #Optional / Default "Time"
   );
```

This constructed object can be used only when NTP is set to "true" at the grid level.

MODULE METHODS

This section describes all the functions that can be applied to an NTP access object.

Infoblox::Grid->ntp_access_list( )

Infoblox::Grid::Member->ntp_access_list( )

Use this function to specify the NTP access for the grid/member.

Example

```
# Create NTP access objects
my $ntpac1 = Infoblox::Grid::NTPAccess->new(
                                            address => "2.2.2.2",
                                            service => "Time",
                                           );

my $ntpac2 = Infoblox::Grid::NTPAccess->new(
                                            address => "4.4.4.4",
                                            service => "Time and NTP control",
                                           );

$grid->ntp_access_list([$ntpac1,$ntpac2]);

my $grid = $session->get(
   object  => "Infoblox::Grid",
   name    => "Infoblox"
 );

 unless ($grid) {
     die("get Grid failed:" ,
          $session->status_code(), $session->status_detail());
 }

$grid->ntp_access_list([$ntpac1,$ntpac2]);
```

```
#Applying the changes to appliance through session.
$session->modify($grid)
     or die("modify Grid failed:" ,
      $session->status_code(), $session->status_detail());
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute value of an NTP access object.

address( )

Use this method to set or retrieve the IPv4 address of the external NTP client. Use "Any" to apply this permission to all clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are an IPv4 address of the external NTP client, or "Any".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address
my $address = $ntp_access->address();
#Modify address
$ntp_access->address("4.4.4.4");
```

service( )

Use this method to specify to which service this NTP Access object applies.

Parameter

Valid values are "Time" or "Time and NTP control".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get service
my $service = $ntp_access->service();
#Modify service
$ntp_access->service("Time and NTP control");
```

NAME

Infoblox::Grid::NTPKey - Grid Network Time Protocol (NTP) key object.

DESCRIPTION

Grid NTPKey object is used by NTP server to authenticate the clients.

CONSTRUCTOR

```
#Constructor for an Grid NTPKey object
 my $ntp_key = Infoblox::Grid::NTPKey->new(
    key_number    =>  $num,                  #Required
    key_string    =>  $string,               #Required
    key_type      =>  "M" | "S" | "A" | "N"  #Optional / Default is "M"
  );
```

MODULE METHODS

The following functions are available to be applied to an NTPKey object.

Infoblox::Grid->ntp_authentication_key( )

Use this function to specify a NTP key at the grid level on the Infoblox appliance. See Infoblox::Grid->ntp_authentication_key() for parameters and return values.

Example

```
#Create a NTPKey object.
my $ntp_key = Infoblox::Grid::NTPKey->new(
                  key_number => 1111,
                  key_type   => "M",
                  key_string => "aaaa"
                );

#Configure NTPKey on the Infoblox grid object
my $responce = $grid->ntp_authentication_key()([$ntp_key]);
```

Infoblox::Grid::Member->ntp_authentication_key( )

Use this function to specify a NTP key at the member level on the Infoblox appliance. See Infoblox::Grid::Member->ntp_authentication_key() for parameters and return values.

Example

```
 #Create a NTPKey object.
  my $ntp_key = Infoblox::Grid::NTPKey->new(
                  key_number => 1111,
                  key_type   => "M",
                  key_string => "aaaa"
                );

#Configure NTPKey on the Infoblox member object
```

```
my $responce = $member->ntp_authentication_key()([$ntp_key]);
```

METHODS

This section describes all the methods that you can used to configure and retrieve the attribute value of a NTPKey object.

key_number( )

Use this method to set or retrieve the key number of the NTPKey object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A positive integer number. Value must be between 1 and 65534.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get key_number
my $number = $ntp_key->key_number();
#Modify key_number
$ntp_key->key_number("3333");
```

key_string( )

Use this method to set or retrieve the key string of the NTPKey object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired key_string in string format defined in the key_type.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get key_string
my $string = $ntp_key->key_string();
#Modify key_string
$ntp_key->key_string("d3e54352e5548080");
```

key_type( )

Use this method to set or retrieve the key type of the NTPKey object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are :"M","S","N","A".The default value is "M".

```
 "M" - For  Message Digest (MD5) in ASCII format and the key_string must be a 1-31 character ASCII
using
          MD5;
 "S" - For Data Encryption Standard (DES) in hex format and key_string must be a 64-bit hexadecimal
         number in DES. The high order 7 bits of each octet form the 56-bit key, and the low order
bit of each
        octet is given a value,  so that the octet maintains odd parity. You must specify leading
zeros so the key
        is exactly 16 hexadecimal digits long and maintains odd parity;

 "A" - For Data Encryption Standard (DES) in ASCII format and the key_string must be a 1-8 character
          ASCII using DES;
 "N" - For Data Encryption Standard (DES) in NTP format and the key_string must be a 64-bit
hexadecimal in
          NTP format. It is the same as the "S" format, but the bits in each octet have been rotated
```

```
one bit right,
          so the parity bit is in the high order bit of the octet. You must specify leading zeros and
odd parity must
          be maintained.
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get key_type
my $type = $ntp_key->key_type();
#Modify key_type
$ntp_key->ntp_key("N");
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to an object such as create, modify, and remove an object. Also this sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
 use strict;
 use Infoblox;

 #Create a session to the Infoblox appliance
 my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
 );
 unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
 }
 print "Session created successfully\n";
```

#Adding an NTPKey object

```
#Create a NTPKey object.
my $ntp_key = Infoblox::Grid::NTPKey->new(
   key_number => 65533,
   key_type   => "M",
   key_string => "aaaa"
);

unless($ntp_key) {
       die("Construct NTP Key object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "NTP Key object created successfully\n";

#Create a NTPServer object.
 my $ntp_server = Infoblox::Grid::NTPServer->new(
    address        => "3.3.3.3",
);

unless($ntp_server) {
       die("Construct NTP server object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "NTP Server object created successfully\n";

my @grid_objs = $session->get(
   object  => "Infoblox::Grid",
   name    => "Infoblox"
 );

 my $grid = $grid_objs[0];
 unless ($grid) {
       die("Get Grid object failed: ",
            $session->status_code() . ":" . $session->status_detail());
  }
  print "Get Grid object found at least 1 matching entry\n";
```

```
$grid->enable_ntp("true");
$grid->ntp_authentication_key([$ntp_key]);
$grid->ntp_server([$ntp_server]);

#Applying the changes to appliance through session.
$session->modify($grid)
     or die("modify Grid failed:" ,
      $session->status_code(), $session->status_detail());
print "Grid modified successfully for adding NTPKey object\n";
```

#Modifying an NTPKey object

```
my $ntp_key = Infoblox::Grid::NTPKey->new(
   key_number => 65532,
   key_type   => "M",
   key_string => "aaaa"
);

my @grid_objs = $session->get(
           object => "Infoblox::Grid",
           name   => "Infoblox"
       );

my $grid = $grid_objs[0];
unless ($grid) {
       die("Get Grid object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get Grid object found at least 1 matching entry\n";

$grid->ntp_authentication_key([$ntp_key]);

#Applying the changes to appliance through session.
$session->modify($grid)
     or die("modify Grid failed:" ,
      $session->status_code(), $session->status_detail());
print "Grid modified successfully for modifying NTPKey object\n";
```

#Removing an NTPKey object

```
#Get Infoblox grid object
my @grid_objs = $session->get(
           object => "Infoblox::Grid",
           name   => "Infoblox"
       );

my $grid = $grid_objs[0];
unless ($grid) {
       die("Get Grid object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get Grid object found at least 1 matching entry\n";

$grid->ntp_authentication_key([]);
#Applying the changes to appliance through session.
$session->modify($grid)
    or die("modify Grid failed for removing NTPKey object:" ,
     $session->status_code(), $session->status_detail());
print "Grid modified successfully for removing NTPKey object\n";
####PROGRAM ENDS####
```

NAME

Infoblox::Grid::NTPServer - Grid Network Time Protocol (NTP) server object.

DESCRIPTION

The Grid NTP server object is used to synchronize the date and time for an Infoblox appliance.

CONSTRUCTOR

```
#Constructor for an Grid NTP server object
 my $ntp_server = Infoblox::Grid::NTPServer->new(
    address        =>  $ipv4addr | $ipv6addr | $fqdn    #Required
    authentication => "true" | "false",                 #Optional / Default "false"
    burst          => "true" | "false",                 #Optional / Default "true"
    iburst         => "true" | "false",                 #Optional / Default "true"
    ntp_key        => [$NTPKey1, $NTPKey2,...]          #Optional / Default is undefined
   );
```

This constructed object can be used only when NTP is set to "true" at the grid level.

MODULE METHODS

This section describes all the functions that can be applied to a NTP server object.

Infoblox::Grid->ntp_server( )

Use this function to specify the NTP server for the grid.

Example

```
#Create a NTPKey object.
my $ntp_key1 = Infoblox::Grid::NTPKey->new(
   key_number => 1111,
   key_type   => "M",
   key_string => "aaaa"
);

#Create a NTPServer object.
 my $ntp_server = Infoblox::Grid::NTPServer->new(
    address        => "3.3.3.3",
    authentication => "true",
    ntp_key        => $ntp_key1
);

my $grid = $session->get(
   object  => "Infoblox::Grid",
   name    => "Infoblox"
 );

 unless ($grid) {
     die("get Grid failed:" ,
```

```
            $session->status_code(), $session->status_detail());
 }

$grid->enable_ntp("true");
$grid->ntp_authentication_key([$ntp_key1]);
$grid->ntp_server([$ntp_server]);

#Applying the changes to appliance through session.
$session->modify($grid)
      or die("modify Grid failed:" ,
       $session->status_code(), $session->status_detail());
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute value of a NTP server object.

address( )

Use this method to set or retrieve the IPv4 or IPv6 address or FQDN of the external NTP server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are IPv4 or IPv6 address or FQDN of the external NTP server.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address
my $address = $ntp_server->address();
#Modify address
$ntp_server->address("4.4.4.4");
```

authentication( )

Use this method to enable or disable the authentication for an NTP server.

Parameter

Specify "true" to enable authentication or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get authentication
my $authentication = $ntp_server->authentication();
#Modify authentication
$ntp_server->authentication("false");
```

burst( )

Use this method to enable or disable BURST operating mode. In BURST operating mode, when the external server is reachable and a valid source of synchronization is available, NTP sends a burst of 8 packets with a 2 second interval between packets.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to eanble the BURST operating mode or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get burst
my $burst = $ntp_server->burst();
#Modify burst
$ntp_server->burst("false");
```

iburst( )

Use this method to enable or disable IBURST operating mode. In IBURST operating mode, when the external server is unreachable, NTP server sends a burst of 8 packets with a 2 second interval between packets.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to eanble the IBURST operating mode or "false" to disable it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get iburst
my $iburst = $ntp_server->iburst();
#Modify iburst
$ntp_server->iburst("false");
```

ntp_key( )

Use this method to set or retrieve the ntp_key used for authentication.

Parameter

Valid value is an array reference that contains Infoblox::Grid::NTPKey objects.

See Infoblox::Grid::NTPKey for parameters and return values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Create a NTPKey object.
my $ntp_key2 = Infoblox::Grid::NTPKey->new(
  key_number => 2222,
  key_type   => "n",
  key_string =>"d3e54352e5548080" );

#Modify NTPServer object
my $ntp_server = Infoblox::Grid::NTPServer->new(
   address        => "3.3.3.3",
   authentication => "true",
   ntp_key        => $ntp_key2
);
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to an object such as create, modify, and remove an object. Also this sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
 use strict;
 use Infoblox;

 #Create a session to the Infoblox appliance
 my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
 );
```

```
  unless ($session) {
    die("Construct session failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
  }
  print "Session created successfully\n";
```

#Adding an NTP server object #Get the grid object. my $result = $session->get(object => "Infoblox::Grid", name => "Infoblox"); unless ($result) { die("get Grid failed:" , $session->status_code(), $session->status_detail()); }

```
  #Create a NTPKey object.
  my $ntp_key1 = Infoblox::Grid::NTPKey->new(
      key_number => 3333,
      key_type   => "S",
      key_string => "a7cb86a4cba80101"
  );

  #Create a NTPServer object.
  my $ntp_server = Infoblox::Grid::NTPServer->new(
      address        => "3.3.3.3",
      authentication => "true",
      ntp_key        => $ntp_key1
  );
   #Modifying the value of the ntp_authentication_key and ntp_server methods, from the grid object.
  $result->enable_ntp("true");
  $result->ntp_authentication_key([$ntp_key1]);
  $result->ntp_server([$ntp_server]);

  #Applying the changes to appliance through session.
  $session->modify($result)
       or die("modify Grid failed:" ,
        $session->status_code(), $session->status_detail());
   print "\n  Modify Grid successful \n";
```

#Modifying an NTP server object #Create a NTPServer object. my $ntp_server = Infoblox::Grid::NTPServer->new(address => "3.3.3.3", authentication => "false",);

```
 $result->ntp_server([$ntp_server]);

 #Applying the changes to appliance through session.
 $session->modify($result)
      or die("modify Grid failed:" ,
       $session->status_code(), $session->status_detail());
 print "\n  Modify grid successful for NTP server object\n";
```

#Removing an NTP server object #Get the grid object. my $result = $session->get(object => "Infoblox::Grid", name => "Infoblox"); unless ($result) { die("get Grid failed:" , $session->status_code(), $session->status_detail()); }

```
 $result->enable_ntp("false");
 $result->ntp_server([]);
 #Applying the changes to appliance through session.
 $session->modify($result)
      or die("modify Grid failed:" ,
       $session->status_code(), $session->status_detail());
 print "\n  Modify grid successful for NTP server object\n";

 ####PROGRAM ENDS####

NAME

Infoblox::Grid::ObjectsChangesTrackingSetting - the object changes tracking setting.

DESCRIPTION

The object changes tracking setting object is used to display the object changes state and to enable or disable the object changes tracking feature.

CONSTRUCTOR

```
my $object_changes = Infoblox::Grid::ObjectsChangesTrackingSetting->new(
    enable => 'true' | 'false', #Optional / Default is 'false'
);
```

MODULE METHODS

+The following functions can be applied to an object changes tracking setting object.

Infoblox::Grid->objects_changes_tracking_setting( )

Use this function to specify the object changes tracking settings for the Grid. See Infoblox::Grid/objects_changes_tracking_setting() for parameters and return values.

Example

```
#Get objects_changes_tracking_setting value
my $value = $object->objects_changes_tracking_setting();

#Construct objects_changes_tracking_setting value
my $objects_changes_tracking_setting = Infoblox::Grid::ObjectsChangesTrackingSetting->new(
    enable => 'true',
);

#Modify objects_changes_tracking_setting value
$object->objects_changes_tracking_setting($objects_changes_tracking_setting);
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of an object changes tracking setting object.

enable( )

Use this method to set or retrieve the flag that indicates whether the object changes tracking feature is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the object changes tracking feature or 'false' to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable value
my $value = $object->enable();

#Modify enable value
$object->enable('true');
```

enable_completion( )

Use this method to retrieve the object changes tracking completion percentage. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an unsigned integer between 0 and 100.

Example

```
#Get enable_completion value
my $value = $object->enable_completion();
```

max_objs_to_track( )

Use this method to set or retrieve the maximum number of objects retained for change tracking.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_objs_to_track value
my $value = $object->max_objs_to_track();

#Modify max_objs_to_track value
$object->max_objs_to_track(10);
```

max_time_to_track( )

Use this method to set or retrieve the maximum time period (in seconds) to track the deleted object changes.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer that represents time period (in seconds).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_time_to_track value
my $value = $object->max_time_to_track();

#Modify max_time_to_track value
```

```
$object->max_time_to_track(10);
```

state( )

Use this method to retrieve the object changes tracking state. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid values are 'ENABLING', 'ENABLED', 'DISABLED' and 'ENABLING_ERROR'.

Example

```
#Get state value
my $value = $object->state();
```

NAME

Infoblox::Grid::ParentalControl::MSP - A Parental Control managed service provider object.

DESCRIPTION

The Parental Control managed service provider object is used to configure list of service providers that are managed by the Parental Control subscriber site.

CONSTRUCTOR

```
my $nas_gateway = Infoblox::Grid::ParentalControl::MSP->new(
    address => $ipv4addr, # Required
);
```

MODULE METHODS

The following functions are available to be applied to a Parental Control managed service provider object.

Infoblox::Grid::ParentalControl::SubscriberSite->msps( )

Use this method to set or retrieve the list of Parental Control managed service providers.

See Infoblox::Grid::ParentalControl::SubscriberSite->msps() for parameters and return values.

Example

```
#Get msps value
my $value = $object->msps();

#Construct Parental Control MSP
my $msp = Infoblox::Grid::ParentalControl::MSP->new(
    address => '10.0.10.10',
);

#Modify msps value
$object->msps([$msp]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a Parental Control managed service provider object.

address( )

Use this method to set or retrieve the managed service provider IP address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is desired IPv4 address in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address value
my $address = $object->address();

#Modify address value
$object->address('10.0.0.10');
```

NAME

Infoblox::Grid::ParentalControl::NAS::AVP - A NAS accounting value pair object.

DESCRIPTION

The NAS accounting value pair object is used in Parental Control Subscriber configuration for extracting accounting information from accounting protocols logs.

CONSTRUCTOR

```
my $avp = Infoblox::Grid::ParentalControl::NAS::AVP->new(
    name          => $string,                                          #Required
    value_type    => 'BYTE' | 'DATE' | 'INTEGER' | 'INTEGER64',
                     | 'IPADDR' | 'IPV6ADDR' | 'IPV6IFID' | 'IPV6PREFIX',
                     | 'OCTETS' | 'SHORT' | 'STRING'                   #Required
    type          => $uint,                                            #Required
    vendor_id     => $uint,                                            #Optional / Default is undefined
    vendor_type   => $uint,                                            #Optional / Default is undefined
    comment       => $string,                                          #Optional / Default is undefined
    is_restricted => 'true' | 'false',                                 #Optional / Default is 'false'
    user_defined  => 'true' | 'false',                                 #Optional / Default is 'true'

);
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a accounting value pair object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct NAS AVP object
my $nas_avp = Infoblox::Grid::ParentalControl::NAS::AVP->new(
    name        => 'address_avp1',
    value_type  => 'ADDRESS',
    type        => 10,
    vendor_id   => 1,
    vendor_type => 20,
);

#Submit for addition
```

```
my $response = $session->add($nas_avp);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

Apply the following attributes to get a specific NAS AVP object:

```
name        - Optional. The string that contains NAS AVP object name.
value_type  - Optional. The string that represents the NAS AVP value type.
type        - Optional. The unsinged integer that represents the NAS AVP type.
vendor_id   - Optional. The unsigned integer that represents the NAS AVP vendor identifier.
vendor_type - Optional. The unsigned integer that represents the NAS AVP vendor type.
comment     - Optional. The descriptive comment in string format.
```

Example

```
#Get object matching the given name
my $object = $session->get(
    object => 'Infoblox::Grid::ParentalControl::NAS::AVP',
    name   => 'address_avp1',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify vendor_id value
$object->vendor_id(10);

#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, use `get()` or `search()` to retrieve the specific object first, and then submit this object for removal.

Example

```
#Get the NAS AVP object matching the given name
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::ParentalControl::NAS::AVP',
    name   => 'address_avp1',
);

#Find the desired object from the retrieved list
my $object = @retrieved_objs[0];

#Submit for removal
my $response = $session->remove($object);
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

Apply the following attributes to get a specific NAS AVP object:

```
name        - Optional. The string that contains NAS AVP object name (regexp).
value_type  - Optional. The string that represents the NAS AVP value type (exact value).
type        - Optional. The unsinged integer that represents the NAS AVP type (exact value).
vendor_id   - Optional. The unsigned integer that represents the NAS AVP vendor identifier (exact
value).
vendor_type - Optional. The unsigned integer that represents the NAS AVP vendor type (exact value).
comment     - Optional. The descriptive comment in string format (regexp).
```

Example

```
#Search for object matching the given name pattern
my @objects = $session->search(
    object => 'Infoblox::Grid::ParentalControl::NAS::AVP',
```

```
        name    => 'address_avp.*',
);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a accounting value pair object.

comment( )

Use this method to set or retrieve the descriptive comment for the AVP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $comment = $object->comment();

#Modify comment value
$object->comment('comment changed');
```

domain_types( )

Use this method to set or retrieve the domain types that are applicable to AVP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is array that contains following values: 'ANCILLARY', 'IP_SPACE_DIS', 'NAS_CONTEXT', 'SUBS_ID'.

By default all domain types are applicable for AVP.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_types value
my $domain_types = $object->domain_types();

#Modify domain_types value
$object->domain_types(['ANCILLARY', 'IP_SPACE_DIS']);
```

is_restricted( )

Use this method to set or retrieve the flag that indicates whether the AVP is restricted to particular AVP domains or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable AVP domain restriction AVP and 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get is_restricted value
my $is_restricted = $object->is_restricted();
```

```
#Modify is_restricted value
$object->is_restricted('true');
```

name( )

Use this method to set or retrieve the AVP name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired AVP name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();

#Modify name value
$object->name('address_avp1');
```

type( )

Use this method to set or retrieve the AVP vendor type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 255.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get type value
my $type = $object->type();

#Modify type value
$object->type(11);
```

user_defined( )

Use this method to retrieve the flag that indicates whether this AVP is user-defined or a system default. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get user_defined value
my $user_defined = $object->user_defined();
```

value_type( )

Use this method to set or retrieve the AVP value type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'BYTE', 'DATE', 'INTEGER', 'INTEGER64', 'IPADDR', 'IPV6ADDR', 'IPV6IFID', 'IPV6PREFIX', 'OCTETS', 'SHORT' and 'STRING'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get value_type value
my $value_type = $object->value_type();

#Modify value_type value
$object->value_type('DATE');
```

vendor_id( )

Use this method to set or retrieve the AVP vendor identifier.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get vendor_id value
my $vendor_id = $object->vendor_id();

#Modify vendor_id value
$object->vendor_id(11);
```

vendor_type( )

Use this method to set or retrieve the AVP vendor specific type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 255.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get vendor_type value
my $vendor_type = $object->vendor_type();

#Modify vendor_type value
$object->vendor_type(11);
```

NAME

Infoblox::Grid::ParentalControl::NAS::Gateway - A Parental Control network accounting server gateway object.

DESCRIPTION

The Parental Control network accounting server (NAS) gateway object provides configuration for transmission of authentication protocol accounting infromation to the NIOS accounting collector.

CONSTRUCTOR

```
my $nas_gateway = Infoblox::Grid::ParentalControl::NAS::Gateway->new(
    name          => $string,                    # Required
    address       => $ipv4addr,                  # Required
    shared_secret => $string,                    # Optional
    send_ack      => 'true' | 'false',           # Optional / Default is 'false'
    comment       => $string,                    # Optional / Default is undefined
);
```

MODULE METHODS

The following functions are available to be applied to a Parental Control network accounting server gateway object.

Infoblox::Grid::ParentalControl::SubscriberSite->nas_gateways( )

Use this method to set or retrieve the NAS gateways associated with subscriber site.

See Infoblox::Grid::ParentalControl::SubscriberSite->nas_gateways() for parameters and return values.

Example

```
#Get nas_gateways value
my $nas_gateways = $object->nas_gateways();

#Construct first gateway
my $gw1 = Infoblox::Grid::ParentalControl::NAS::Gateway->new(
    name          => 'gateway-1',
    address       => '10.1.1.1',
    shared_secret => 'secret',
);

#Construct first gateway
my $gw2 = Infoblox::Grid::ParentalControl::NAS::Gateway->new(
    name          => 'gateway-2',
    address       => '2001:db8::1',
    shared_secret => 'secret',
    send_ack      => 'true',
);

#Modify nas_gateways value
$object->nas_gateways([$gateway1, $gateway2]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a Parental Control network accounting server gateway object.

address( )

Use this method to set or retrieve the NAS gateway IP address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is desired IPv4 address in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address value
my $address = $object->address();

#Modify address value
$object->address('10.0.0.10');
```

comment( )

Use this method to set or retrieve the NAS gateway comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $comment = $object->comment();

#Modify comment value
$object->comment('nas gateway comment');
```

message_rate( )

Use this method to retrieve the vendor specific accounting messages rate. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get message_rate value
my $message_rate = $object->message_rate();
```

name( )

Use this method to set or retrieve the NAS gateway object name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();

#Modify name value
$object->name('accounting_log_server');
```

send_ack( )

Use this method to set or retrieve the flag that indicates whether the acknowledgement of the accounting packets is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable acknowledgement of the accounting packets or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get send_ack value
my $send_ack = $object->send_ack();

#Modify send_ack value
$object->send_ack('true');
```

shared_secret( )

Use this method to set or retrieve the MD5 phrase for the accounting data. This is a write-only attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired MD5 phrase in a string format.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify shared_secret value
$object->shared_secret('secret');
```

NAME

Infoblox::Grid::ParentalControl::SiteMember - A Parental Control site member object.

DESCRIPTION

The Parental Control site member object associate particular Grid member with it's role in process of collecting and consuming the authentication information and the Parental Control site the feature is deployed on.

CONSTRUCTOR

```
my $site_member = Infoblox::Grid::ParentalControl::SiteMember->new(
    name => $string,                                  #Required
    type => 'COLLECTOR' | 'NONE' | 'BOTH' | 'CLIENT', #Optional / Default is 'NONE'
);
```

MODULE METHODS

The following functions are available to be applied to a Parental Control site member object.

Infoblox::Grid::ParentalControl::SubscriberSite->members( )

Use this method to set or retrieve the Grid members associatied with subscriber site.

See Infoblox::Grid::ParentalControl::SubscriberSite->members() for parameters and return values.

Example

```
#Get members value
my $members = $object->members();

#Construct first member
my $m1 = Infoblox::Grid::ParentalControl::SiteMember->new(
    name => 'infoblox.localdomain',
    type => 'NONE',
);

#Construct second member
my $m2 = Infoblox::Grid::ParentalControl::SiteMember->new(
    name => 'imc-collector',
    type => 'COLLECTOR',
);

#Modify members value
$object->members([$m1, $m2]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a Parental Control site member object.

name( )

Use this method to set or retrieve the name of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();

#Modify name value
$object->name('my_collector');
```

type( )

Use this method to set or retrieve the type of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'BOTH', 'COLLECTOR', 'CLIENT' and 'NONE'. The default value is 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get type value
my $type = $object->type();

#Modify type value
$object->type('CLIENT');
```

NAME

Infoblox::Grid::ParentalControl::Subscriber - Parental Control subscriber properties.

DESCRIPTION

The Parental Control subscriber properties contains user defined Radius subscriber information of which will be used by DNS/RPZ for reporting and logging violations.

Note that this object cannot be added or deleted. Only get and modify operations are supported.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to the object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
#Get object
my $object = $session->get(
    object => 'Infoblox::Grid::ParentalControl::Subscriber',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify interim_accounting_interval value
$object->interim_accounting_interval(20);

#Submit modification
my $response = $session->modify($object);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of the object.

ancillaries( )

Use this method to set or retrieve the ordered list of ancillary AVP fields.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains existing AVP names in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ancillaries value
my $ancillaries = $object->ancillaries();

#Modify ancillaries value
$object->ancillaries(['avp1', 'avp2']);
```

enable_parental_control( )

Use this method to set or retrieve the flag that indicates whether the Parental Control feature is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable Parental Control and 'false to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_parental_control value
my $enable_parental_control = $object->enable_parental_control();

#Modify enable_parental_control value
$object->enable_parental_control('true');
```

enable_mgmt_only_nas( )

Use this method to set or retrieve the flag that indicates whether the NAS RADIUS traffic is accepted over MGMT port only.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to restrict NAS RADIUS traffic to MGMT port only, and 'false' to disable this restriction. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_mgmt_only_nas value
my $enable_mgmt_only_nas = $object->enable_mgmt_only_nas();

#Modify enable_mgmt_only_nas value
$object->enable_mgmt_only_nas('true');
```

interim_accounting_interval( )

Use this method to set or retrieve the time that is required for collector to be fully populated.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is unsigned integer between 1 and 200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interim_accounting_interval value
my $interim_accounting_interval = $object->interim_accounting_interval();

#Modify interim_accounting_interval value
$object->interim_accounting_interval(20);
```

ip_anchors( )

Use this method to set or retrieve the ordered list of IP anchors AVPs.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains existing AVP names in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ip_anchors value
my $ip_anchors = $object->ip_anchors();

#Modify ip_anchors value
$object->ip_anchors(['avp1', 'avp2']);
```

ip_space_discriminator( )

Use this method to set or retrieve the IP space discriminator AVP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is existing AVP name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ip_space_discriminator value
my $ip_space_discriminator = $object->ip_space_discriminator();

#Modify ip_space_discriminator value
$object->ip_space_discriminator('avp1');
```

ip_space_discriminator_regexp( )

Use this method to set or retrieve the regular expression for IP space discriminator information extraction.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ip_space_discriminator_regexp value
```

```
my $ip_space_discriminator_regexp = $object->ip_space_discriminator_regexp();

#Modify ip_space_discriminator_regexp value
$object->ip_space_discriminator_regexp('regexp');
```

ip_space_discriminator_subexpression( )

Use this method to set or retrieve the regular expression capturing group number to extract the IP space discriminator information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is unsigned integer between 0 and 8. 0 group returns full matched expression.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ip_space_discriminator_subexpression value
my $ip_space_discriminator_subexpression = $object->ip_space_discriminator_subexpression();

#Modify ip_space_discriminator_subexpression value
$object->ip_space_discriminator_subexpression(2);
```

nas_context_info( )

Use this method to set or retrieve the subscriber NAS context information AVP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is existing AVP name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nas_context_info value
my $nas_context_info = $object->nas_context_info();

#Modify nas_context_info value
$object->nas_context_info('avp1');
```

subscriber_id( )

Use this method to set or retrieve the subscriber ID AVP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is existing AVP name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscriber_id value
my $subscriber_id = $object->subscriber_id();

#Modify subscriber_id value
$object->subscriber_id('avp1');
```

subscriber_id_regexp( )

Use this method to set or retrieve the regular expression for extracting subscriber ID information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is desired regular expression in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscriber_id_regexp value
my $subscriber_id_regexp = $object->subscriber_id_regexp();

#Modify subscriber_id_regexp value
$object->subscriber_id_regexp('regexp');
```

subscriber_id_subexpression( )

Use this method to set or retrieve the regular expression capturing group number to extract the subscriber ID information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is unsigned integer between 0 and 8. 0 group returns full matched expression.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscriber_id_subexpression value
my $subscriber_id_subexpression = $object->subscriber_id_subexpression();

#Modify subscriber_id_subexpression value
$object->subscriber_id_subexpression(2);
```

NAME

Infoblox::Grid::ParentalControl::SubscriberSite - a Parental Control subscriber site object

---

DESCRIPTION

CONSTRUCTOR

```
 my $subscriber_site = Infoblox::Grid::ParentalControl::SubscriberSite->new(
    name                  => $string,                                                  #
Required
    maximum_subscribers   => $uint,                                                    #
Required
    nas_port              => $uint,                                                    #
Required
    comment               => $string,                                                  #
Optional / Default is undefined
    members               => [$site_member1, $site_member2, ...],                      #
Optional / Default is empty list
    msps                  => [$msp1, $msp2, ...],                                      #
Optional / Default is empty list
    nas_gateways          => [$gateway1, $gateway2, ...],                              #
Optional / Default is empty list
    blocking_ipv4_vip1    => $ipv4addr,                                                #
Optional / Default is undefined
    blocking_ipv6_vip1    => $ipv6addr,                                                #
Optional / Default is undefined
    blocking_ipv4_vip2    => $ipv4addr,                                                #
Optional / Default is undefined
    blocking_ipv6_vip2    => $ipv6addr,                                                #
Optional / Default is undefined
    extattrs              => { $string => $extattr, ... },                             #
Optional / Default is undefined
    extensible_attributes => {$string => $string | $num, $string => [ $string | $num, ... ], ... } #
Optional / Default is undefined
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

The following functions can be applied to a Infoblox::Grid::ParentalControl::SubscriberSite object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $object = Infoblox::Grid::ParentalControl::SubscriberSite->new(
   name                => 'site1',
   maximum_subscribers => '20000',
   nas_port            => '1919',
   comment             => 'site1 comment',
);

#Submit for addition
my $response = $session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
 Apply the following attributes to get a specific Infoblox::Grid::ParentalControl::SubscriberSite
object.
  name                - Optional. The Parental Control subscriber site name.
  comment             - Optional. The Parental Control subscriber site comment.
  extattrs            - Optional. A hash reference containing Infoblox::Grid::Extattr object.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  blocking_ipv4_vip1    - Optional. The Parental Control primary VIP IPv4 address of the blocking
server.
  blocking_ipv6_vip1    - Optional. The Parental Control primary VIP IPv6 address of the blocking
server.
  blocking_ipv4_vip2    - Optional. The Parental Control secondary VIP IPv4 address of the blocking
server.
  blocking_ipv6_vip2    - Optional. The Parental Control secondary VIP IPv6 address of the blocking
server.
```

Example

```
# search for the object which name is 'test.com'
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ParentalControl::SubscriberSite',
    'name'   => 'test.com',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# modify object object
$object->comment('comment change');

# Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::ParentalControl::SubscriberSite',
    name   => 'site1');

#Find the desired object from the retrieved list.
my $desired_object = $retrieved_objs[0];

# Submit for removal
my $response = $session->remove($desired_object);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
 Apply the following attributes to search for a specific
Infoblox::Grid::ParentalControl::SubscriberSite object.
  name                  - Optional. The Parental Control subscriber site name (regexp).
  comment               - Optional. The Parental Control subscriber site comment (regexp).
  extattrs              - Optional. A hash reference containing Infoblox::Grid::Extattr object.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  blocking_ipv4_vip1    - Optional. The Parental Control primary VIP IPv4 address of the blocking
server (regexp).
  blocking_ipv6_vip1    - Optional. The Parental Control primary VIP IPv6 address of the blocking
server (regexp).
  blocking_ipv4_vip2    - Optional. The Parental Control secondary VIP IPv4 address of the blocking
server (regexp).
  blocking_ipv6_vip2    - Optional. The Parental Control secondary VIP IPv6 address of the blocking
server (regexp).
```

Example

```
 # search for objects which name contains test and primary IPv6 address of the blocking server
contains '2:'
 my @retrieved_objs = $session->search(
     'object'             => 'Infoblox::Grid::ParentalControl::SubscriberSite',
     'name'               => 'test.*',
     'blocking_ipv6_vip1' => '2:.*',
 );

 # search for objects defining 'Santa Clara' for 'Site' extensible attribute
 my @retrieved_objs = $session->search(
     object               => 'Infoblox::Grid::ParentalControl::SubscriberSite',
     extensible_attributes => {'Site' => 'Santa Clara'},
 );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a Parental Control subscriber site object.

comment( )

Use this method to set or retrieve Parental Control subscriber site comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is desired comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
 #Get comment
 my $value = $object->comment();

 #Modify comment
 $object->comment('new comment');
```

blocking_ipv4_vip1( )

Use this method to set or retrieve the primary IPv4 address of the blocking server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IPv4 address in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blocking_ipv4_vip1 value
my $blocking_ipv4_vip1 = $object->blocking_ipv4_vip1();

#Modify blocking_ipv4_vip1 value
$object->blocking_ipv4_vip1('10.0.10.1');
```

blocking_ipv4_vip2( )

Use this method to set or retrieve the secondary IPv4 address of the blocking server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IPv4 address in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blocking_ipv4_vip2 value
my $blocking_ipv4_vip2 = $object->blocking_ipv4_vip2();

#Modify blocking_ipv4_vip2 value
$object->blocking_ipv4_vip2('10.0.10.1');
```

blocking_ipv6_vip1( )

Use this method to set or retrieve the primary IPv6 address of the blocking server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IPv6 address in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blocking_ipv6_vip1 value
my $blocking_ipv6_vip1 = $object->blocking_ipv6_vip1();

#Modify blocking_ipv6_vip1 value
$object->blocking_ipv6_vip1('2001:db8::1');
```

blocking_ipv6_vip2( )

Use this method to set or retrieve the secondary IPv6 address of the blocking server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IPv6 address in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blocking_ipv6_vip2 value
my $blocking_ipv6_vip2 = $object->blocking_ipv6_vip2();

#Modify blocking_ipv6_vip2 value
$object->blocking_ipv6_vip2('2002:db8::1');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Parental Control subscriber site object.

Parameter

Valid value is a hash reference that contains the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you have specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs value
my $extattrs = $object->extattrs();

#Modify extattrs value
$object->extattrs({'Site' => $extattr1, 'Administrator' => $extattr2});
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a Parental Control subscriber site object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you have specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes value
my $extensible_attributes = $object->extensible_attributes();
#Modify extensible attributes
$object->extensible_attributes({'Site' => 'Santa Clara', 'Administrator' => ['Peter', 'Tom']});
```

maximum_subscribers( )

Use this method to set or retrieve the port number to reach the collector.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 10 000 and 10 000 000.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get maximum_subscribers value
my $maximum_subscribers = $object->maximum_subscribers();

#Modify maximum_subscribers value
$object->maximum_subscribers('20000');
```

members( )

Use this method to set or retrieve the Grid members associatied with subscriber site.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::ParentalControl::SiteMember.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Construct first member
my $m1 = Infoblox::Grid::ParentalControl::SiteMember->new(
    name => 'infoblox.localdomain',
    type => 'NONE',
);

#Construct second member
my $m2 = Infoblox::Grid::ParentalControl::SiteMember->new(
    name => 'imc-collector',
    type => 'COLLECTOR',
);

#Get members value
my $members = $object->members();

#Modify members value
$object->members([$m1, $m2]);
```

msps( )

Use this method to set or retrieve the list of Parental Control managed service providers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::ParentalControl::MSP objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Exmaple

```
#Get msps value
my $value = $object->msps();

#Construct Parental Control MSP
my $msp = Infoblox::Grid::ParentalControl::MSP->new(address => '10.0.10.10');

#Modify msps value
$object->msps([$msp]);
```

name( )

Use this method to set or retrieve a name of the Parental Control subscriber site.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in string format.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Exmaple

```
#Get name value
my $value = $object->name();
```

```
#Modify name value
$object->name('test2');
```

nas_gateways( )

Use this method to set or retrieve the NAS gateways associated with subscriber site.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::ParentalControl::NAS::Gateway.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nas_gateways value
my $nas_gateways = $object->nas_gateways();

#Construct first gateway
my $gw1 = Infoblox::Grid::ParentalControl::NAS::Gateway->new(
    name          => 'gateway-1',
    address       => '10.1.1.1',
    shared_secret => 'secret',
);

#Construct first gateway
my $gw2 = Infoblox::Grid::ParentalControl::NAS::Gateway->new(
    name          => 'gateway-2',
    address       => '2001:db8::1',
    shared_secret => 'secret',
    send_ack      => 'true',
);

#Modify nas_gateways value
$object->nas_gateways([$gw1, $gw2]);
```

nas_port( )

Use this method to set or retrieve the port number to reach the collector.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nas_port value
my $nas_port = $object->nas_port();

#Modify nas_port value
$object->nas_port('1919');
```

NAME

Infoblox::Grid::PersonalSmartFolder - Personal Smart Folder object.

DESCRIPTION

A Personal Smart Folder object is used for data organization.

CONSTRUCTOR

```
 my $group = Infoblox::Grid::PersonalSmartFolder->new(
     name                => $string,                                          #Required
     comment             => $string,                                          #Optional
/ Default is undefined
     group_bys           => [$GroupbyItem1, $GroupbyItem2],                   #Optional
/ Default is undefined
     query_items         => [$QueryItem1, $QueryItem2],                       #Optional
/ Default is undefined
 );
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a Personal Smart Folder object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct the QueryItem in-memory object
my $query_item1 = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                => "location",
    operator            => "eq",
    value               => "Santa Clara",
);

#Construct the PersonalSmartFolder object
my $group_by_state = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                              enable_grouping => 'true',
                                                              value => "State",
                                                              value_type => "EXTATTR",
                                                             );

my $smart_folder = Infoblox::Grid::PersonalSmartFolder->new(
    name                => "smartfolder1",
    comment             => "personal smart folder",
    group_bys           => [$group_by_state],
    query_items         => [$query_item1],
```

```
);
# Submit for addition
my $response = $session->add( $smart_folder );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific PersonalSmartFolder object:

 name      - Required. PersonalSmartFolder name in string format.
 comment   - Optional. Comment in string format.
```

Example

```
my @retrieved_objs = $session->get(
    object     => "Infoblox::Grid::PersonalSmartFolder",
    name       => "smartfolder1" );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment.
$smart_folder->comment("This is a modified comment");
# Submit modification
my $response = $session->modify( $smart_folder );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, use `get()` or `search()` to retrieve the specific object first, and then submit this object for removal.

Example

```
# Get the PersonalSmartFolder objects using a name
my @retrieved_objs = $session->get(
    object     => "Infoblox::Grid::PersonalSmartFolder",
    name       => "smartfolder1" );
# find the desired object from the retrieved list.
my $desired_smart_folder = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_smart_folder );
```

Infoblox::Session->search( )

Use this method to search for Personal Smart Folder objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific PersonalSmartFolder object:

 name      - Optional. PersonalSmartFolder name in string format (regular expression).
 comment   - Optional. Comment in string format (regular expression).
```

Example

```
# search for all PersonalSmartFolder objects that start with "smartfolder"
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::PersonalSmartFolder",
    name   => "smartfolder.*" );
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a PersonalSmartFolder object.

comment( )

Use this method to set or retrieve the comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Pertinent information about the personal smart folder. Comment in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $smart_folder->comment();
#Modify comment
$smart_folder->comment("This is the modified comment for smartfolder1");
```

group_bys( )

Use this method to set or retrieve the group_bys value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::SmartFolder::GroupBy object(s). The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $group_by_state = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                              enable_grouping => 'true',
                                                              value => "State",
                                                              value_type => "EXTATTR",
                                                             );

#Get group_by value
my $group_by = $smart_folder->group_by();
#Modify group_by value
$smart_folder->group_bys([$group_by_state]);
```

name( )

Use this method to set or retrieve the name of a personal smart folder.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Text with the name of the personal smart folder.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $smart_folder->name();
```

query_items( )

Use this method to set or retrieve the query items. If query items are not specified when you `add()` a smart folder, the server automatically assigns a default query item for the smart folder. This default query item is "type=Network/Zone/Range/Member". This ensures that objects are included in searches for these 4 types, by default. When you `modify()` a smart folder, the server keeps the query items provided by the client and does not add the default items.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::Grid::SmartFolder::QueryItem object(s). The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get query items
my $query_items = $smart_folder->query_items();

#Modify query items
my $query_item1 = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                => "location",
    operator            => "eq",
    value               => "Santa Clara",
);
$smart_folder->query_items([$query_items1]);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to an PersonalSmartFolder object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
              master   => "192.168.1.2", #appliance host ip
              username => "admin",       #appliance user login
              password => "infoblox"     #appliance password
              );

unless ($session) {
       die("Construct session failed: ",
              Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

# Add a network with extensible attributes

my %extensible_attributes=(
    'Region' => 'Santa Clara County',
    'Country' => 'USA',
    'State' => 'California',
    'Site' => 'Santa Clara',
    'Building' => 'HQ',
    'VLAN' => '1',
);

my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/24",
    extensible_attributes => \%extensible_attributes,
);
unless ($network) {
    die("Construct Network failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network created successfully\n";

$session->add($network)
    or die("Add Network object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "Network object added to server successfully\n";
```

#Create a PersonalSmartFolder object

```
my $query_item = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                    => "Country",
    is_extensible_attribute => "true",
    operator                => "eq",
    value                   => "USA",
);

unless ($query_item) {
    die("Construct query item object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Smart folder query item object created successfully\n";

my $smart_folder = Infoblox::Grid::PersonalSmartFolder->new(
    name                    => "my_folder_personal",
    comment                 => "my personal folder",
    query_items             => [$query_item],
);

unless ($smart_folder) {
    die("Construct personal smart folder object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Smart folder object created successfully\n";

#Add the PersonalSmartFolder object to the Infoblox appliance through a session
$session->add($smart_folder)
    or die("Add PersonalSmartFolder object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "PersonalSmartFolder object added to server successfully\n";
```

#Search for a PersonalSmartFolder

```
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::PersonalSmartFolder",
    name   => "my_folder.*"
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Search for a PersonalSmartFolder object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search for a PersonalSmartFolder object found at least 1 matching entry\n";
```

#Get and modify a PersonalSmartFolder object

```
#Get the PersonalSmartFolder object from Infoblox appliance through a session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::PersonalSmartFolder",
    name   => "my_folder_personal"
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Get PersonalSmartFolder object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get PersonalSmartFolder object found at least 1 matching entry\n";

#Modify the PersonalSmartFolder object
$object->name("my_folder_personal_renamed");
$object->comment("modified personal smart folder");

#Apply the changes.
$session->modify($object)
    or die("Modify PersonalSmartFolder object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "PersonalSmartFolder object modified successfully \n";
```

#Remove a PersonalSmartFolder object

```
#Get the PersonalSmartFolder object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::PersonalSmartFolder",
    name   => "my_folder_personal_renamed"
```

```
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get PersonalSmartFolder object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get PersonalSmartFolder object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove PersonalSmartFolder object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "PersonalSmartFolder object removed successfully \n";
```

#Cleanup

```
#Get the Network object through the session
my @retrieved_objs = $session->get(
    object  => "Infoblox::DHCP::Network",
    network => "10.0.0.0/24"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get Network object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Network object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove Network object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "Network object removed successfully \n";

####PROGRAM ENDS####
```

NAME

Infoblox::Grid::RecordNamePolicy - Manages the DNS record name policies defined at the grid level.

DESCRIPTION

Record name policy defines the DNS record name format restrictions at the grid level.

CONSTRUCTOR

```
my $policy = Infoblox::Grid::RecordNamePolicy->new(
             name  => $string, #Required
             regex => $regex   #Required
);
```

MODULE METHODS

The following functions are available to apply to the record name policy object.

Infoblox::Grid::DNS->record_name_policies( )

Use this function to specify a record name policy at the grid level in the Infoblox appliance.

Example

```
#Create a RecordNamePolicy object.
my $policy = Infoblox::Grid::RecordNamePolicy->new(
                 name  => "test",
                 regex => "^[a-zA-Z0-9]+\$",
               );

#Configure record name policy on the Infoblox grid object
my $response = $grid_dns->record_name_policies([$policy]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attributes values of a record name policy object.

name( )

Use this method to set or retrieve the record name policy name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

String with the name of the record name policy.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $policy->name();
#Modify name
$policy->name("new_name");
```

regex( )

Use this method to set or retrieve the record name policy in regular expression format.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The record name policy in regular expression format. It should follow POSIX regular expression rules.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get regex
my $regex = $policy->regex();
#Modify regex
$policy->regex("^[a-zA-Z0-9]*\$");
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to a record name policy object, such as create, modify, and remove. This sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a record name policy object

```
my $policy1 = Infoblox::Grid::RecordNamePolicy->new(
    name  => "Allow Any",
    regex => ".+",
    );
unless ($policy1) {
     die("Construct record name policy1 object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Record name policy1 object created successfully\n";

my $policy2 = Infoblox::Grid::RecordNamePolicy->new(
      name  => "Allow Underscore",
      regex => "^[-a-zA-Z0-9_.]+\$",
    );

unless ($policy2) {
     die("Construct record name policy1 object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Record name policy2 object created successfully\n";

my $policy3 = Infoblox::Grid::RecordNamePolicy->new(
      name  => "Strict Hostname Checking",
```

```
      regex => "^[a-zA-Z0-9]\$|^[a-zA-Z0-9][-a-zA-Z0-9.]*[a-zA-Z0-9]\$",
    );

unless ($policy3) {
     die("Construct record name policy3 object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Record name policy3 object created successfully\n";

my $policy4 = Infoblox::Grid::RecordNamePolicy->new(
    name  => "test",
    regex => "^[a-zA-Z0-9]+\$",
    );
unless ($policy4) {
     die("Construct record name policy3 object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Record name policy4 object created successfully\n";
```

#Get the Member DNS object to add a record name policy object to it

```
my $grid_dns = $session->get( "object" => "Infoblox::Grid::DNS", "grid" => "Infoblox");

unless ($grid_dns) {
         die("Get Grid DNS failed: ",
             $session->status_code() . ":" . $session->status_detail());
 }
$grid_dns->record_name_policies([$policy1,$policy2,$policy3,$policy4]);
$session->modify($grid_dns)
      or die("modify Grid DNS failed:" ,
      $session->status_code(), $session->status_detail());
print "Modify grid DNS successful for record name policy object\n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::RestartBannerSetting - The restart banner setting.

DESCRIPTION

The Restart Banner Setting object controls the banner displayed for Grid restart.

CONSTRUCTOR

```
my $restart = Infoblox::Grid::RestartBannerSetting->new(
    enable                    => "true" | "false", #Mandatory
    enable_double_confirmation => "true" | "false", #Optional / Default is "false"
);
```

MODULE METHODS

The following functions are available to apply to a restart banner setting object.

Infoblox::Grid->restart_banner_setting( )

Use this function to specify the restart banner settings for the Grid. See Infoblox::Grid->restart_banner_setting() for parameters and return values.

Example

```
my $grid = $session->get(object => 'Infoblox::Grid');

my $banner = Infoblox::Grid::RestartBannerSetting->new(enable => 'true');
$grid->restart_banner_setting($banner);
my $response = $session->modify($grid);
unless($response) {
     die("Modify grid failed: ",
           session->status_code() . ":" . session->status_detail());
}
print "Grid banner setting modified successfully\n";
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a Restart Banner Setting object.

enable( )

Use this method to set the enable flag.

Parameter

Specify "true" to enable the banner or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable
my $enable = $banner->enable();
#Modify enable
$banner->enable("true");
```

enable_double_confirmation( )

Use this method to set the enable_double_confirmation flag. If this flag is set to "true" the user is required to input name before restarting services.

Parameter

Specify "true" to enable double confirmation or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_double_confirmation
my $enable_double_confirmation = $banner->enable_double_confirmation();
#Modify enable_double_confirmation
$banner->enable_double_confirmation("true");
```

NAME

Infoblox::Grid::RIR - Regional Internet Registry (RIR) object.

DESCRIPTION

Regional Internet Registry (RIR) object.

CONSTRUCTOR

```
my $rir = Infoblox::Grid::RIR->new(
   communication_mode    => 'API' | 'EMAIL' | 'NONE', # Required
   name                  => 'RIPE',                   # Optional, Default is 'RIPE'
   email                 => $string,                  # Optional
   override_email        => 'true' | 'false',         # Optional, Default is 'false'
   url                   => $string,                  # Optional
   override_url          => 'true' | 'false',         # Optional, Default is 'false'
);
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a RIR object.

Support for RIR/SWIP must be enabled at the Grid level. See Infoblox::Grid->enable_rir_swip() method.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific RIR object:

 name    - Optional. The RIR name.
```

Example

```
my @retrieved_objs = $session->get(
   object => 'Infoblox::Grid::RIR',
   name   => 'RIPE',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify email of a RIR object.
```

```
$rir->email('support@infoblox.com');
# Submit modification
my $response = $session->modify( $rir );
```

Infoblox::Session->search( )

Use this method to search for RIR objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search a specific RIR object:

 name         - Optional. The RIR name.
```

Example

```
my @retrieved_objs = $session->search(
   object => 'Infoblox::Grid::RIR',
   name   => 'RIPE',
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a RIR object.

communication_mode( )

Use this method to set or retrieve a communication mode for RIR.

Parameter

Valid values are 'API', 'EMAIL' and 'NONE'. The default value is 'API'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir->communication_mode();
#Modify attribute value
$rir->communication_mode('EMAIL');
```

name( )

Use this method to set or retrieve a name of RIR.

Parameter

Valid value is 'RIPE'. The default value is 'RIPE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir->name();
#Modify attribute value
$rir->name('RIPE');
```

email( )

Use this method to set or retrieve an email address for RIR.

Parameter

Email address in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir->email();
#Modify attribute value
$rir->email('support@infoblox.com');
```

url( )

Use this method to set or retrieve the Web API URL for RIR.

Parameter

Web API URL in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir->url();
#Modify attribute value
$rir->url('http://www.infoblox.com');
```

override_email( )

Use this method to set or retrieve the override_email flag of RIR.

Parameter

Specify "true" to override the predefined email address or "false" to use the predefined email address. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir->override_email();
#Modify attribute value
$rir->override_email('true');
```

override_url( )

Use this method to set or retrieve the override_url flag of RIR.

Parameter

Specify "true" to override the predefined Web API URL or "false" to use the predefined Web API URL. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir->override_url();
#Modify attribute value
$rir->override_url('true');
```

NAME

Infoblox::Grid::RIR::Organization - Regional Internet Registry (RIR) organization object.

DESCRIPTION

Regional Internet Registry (RIR) organization object.

CONSTRUCTOR

```
my $rir_org = Infoblox::Grid::RIR::Organization->new(
   id                    => $string,                       # Required
   rir                   => $rir,                          # Required, an Infoblox::Grid::RIR object
   extattrs              => { $string => $extattr, ... },  # Required
   extensible_attributes => $extattrs,                     # Required
   name                  => $string,                       # Required
   maintainer            => $string,                       # Required
   password              => $string,                       # Required, write-only
   sender_email          => $string,                       # Required
);
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to RIR organization object.

Support for RIR/SWIP must be enabled at the Grid level. See Infoblox::Grid->enable_rir_swip() method.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $rir_org = Infoblox::Grid::RIR::Organization->new(
   id                    => 'ORG_ID',
   name                  => 'RIR organization',
   maintainer            => 'support',
   password              => 'infoblox',
   sender_email          => 'support@infoblox.com',
   rir                   => $rir,
   extensible_attributes' => {'RIPE Registry Source' => 'RIPE',
```

```
                                    'RIPE Country' => 'United States (US)',
                                    'RIPE Admin Contact' => 'CA1-TEST',
                                    'RIPE Technical Contact' => 'CT1-TEST',
                                    'RIPE Email' => 'admin@infoblox.com'},
);

#Submit for addition
my $response = $session->add( $rir_org );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific RIR organization object:

 id           - Optional. The RIR Organization ID.
 name         - Optional. The RIR organization name.
 extattrs     - Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->get(
   object => 'Infoblox::Grid::RIR::Organization',
   name   => 'RIR organization',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to set password of a RIR organization object.
$rir_org->password('infoblox');
# Submit modification
my $response = $session->modify( $rir_org );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
   object => 'Infoblox::Grid::RIR::Organization',
   name   => 'RIR organization',
);
#Find the desired object from the retrieved list.
my $desired_rir_org = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_rir_org );
```

Infoblox::Session->search( )

Use this method to search for RIR organization objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search a specific RIR organization object:

 id           - Optional. The RIR Organization ID.
 name         - Optional. The RIR organization name.
 extattrs     - Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->search(
   object => 'Infoblox::Grid::RIR::Organization',
   name   => 'RIR organization',
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve attribute values of the RIR organization object.

id( )

Use this method to set or retrieve RIR Organization ID.

Parameter

RIR Organization ID in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir_org->id();
#Modify attribute value
$rir_org->id('ORG-MC1-RIPE');
```

rir( )

Use this method to set or retrieve RIR object which is associated with the organization.

Parameter

An Infoblox::Grid::RIR object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir_org->rir();
#Modify attribute value
$rir_org->rir($rir);
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a RIR organization object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $rir_org->extattrs();
#Modify extattrs
$rir_org->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a RIR organization object.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values and Infoblox::Grid->enable_rir_swip().

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir_org->extensible_attributes();
#Modify attribute value
$rir_org->extensible_attributes({'RIPE Registry Source' => 'TEST',
                                 'RIPE Country' => 'Canada (CA)',
                                 'RIPE Admin Contact' => 'CA2-TEST',
                                 'RIPE Technical Contact' => 'CT2-TEST',
                                 'RIPE Email' => 'support@infoblox.com'});
```

name( )

Use this method to set or retrieve RIR organization name.

Parameter

RIR organization name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir_org->name();
#Modify attribute value
$rir_org->name('New RIR organization');
```

maintainer( )

Use this method to set or retrieve the RIR organization maintainer.

Parameter

RIR organization maintainer in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir_org->maintainer();
#Modify attribute value
$rir_org->maintainer('support');
```

password( )

Use this method to set the password for RIR organization's maintainer. This is a write-only attribute.

Parameter

The password for RIR organization's maintainer in string format.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set attribute value
$rir_org->password('infoblox');
```

sender_email( )

Use this method to set or retrieve the sender email address for RIR organization.

Parameter

The sender email address for RIR organization in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $rir_org->sender_email();
#Modify attribute value
$rir_org->sender_email('support@infoblox.com');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify, search and remove. This sample also includes error handling for the operations.

#Preparation prior to getting and modifying RIR organization object

```
use strict;
use Infoblox;

#refers to Infoblox Appliance IP address
my $host_ip = "192.168.1.2";

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $grid = $self->{'session'}->get('object' => 'Infoblox::Grid');

unless ($grid) {
    die("Get Grid object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Get Grid successful \n";

$grid->enable_rir_swip('true');

$session->modify($grid)
   or die("Modify Grid failed",
            $session->status_code() . ":" . $session->status_detail());
print "Grid modified successfully \n";
```

#Create RIR organization object

```
my $rir = $self->{'session'}->get('object' => 'Infoblox::Grid::RIR', 'name' => 'RIPE');

unless ($rir) {
    die("Get RIR object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"Get RIR successful \n";

my $rir_org = Infoblox::Grid::RIR::Organization->new(
       'id'            => 'RIR_ORG_ID',
       'name'          => 'RIR organization',
       'maintainer'    => 'support',
       'password'      => 'infoblox',
       'sender_email'  => 'support@infoblox.com',
```

```
        'rir'           => $rir,
        'extensible_attributes' => {'RIPE RIPE Registry Source' => 'RIPE',
                                    'RIPE Country' => 'United States (US)',
                                    'RIPE Admin Contact' => 'CA1-TEST',
                                    'RIPE Technical Contact' => 'CT1-TEST',
                                    'RIPE Email' => 'admin@infoblox.com'},
);

unless ($rir_org) {
    die("Construct RIR organization object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"RIR organization object created successfully\n";

my $response = $session->add($rir_org);

unless ($response) {
    die("Add RIR organization failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"RIR organization added successfully \n";
```

#Search for RIR organization object

```
my @retrieved_objs = $session->search(
   object => 'Infoblox::Grid::RIR::Organization',
   id     => 'RIR_ORG_ID',
);

$rir_org = $retrieved_objs[0];

unless ($rir_org) {
        die("Search RIR organization object failed: ",
                $session->status_code() . ":" . $session->status_detail());
}
print "Search RIR organization object found at least 1 matching entry\n";
```

#Get and modify RIR organization object

```
@retrieved_objs = $session->get(
   object => 'Infoblox::Grid::RIR::Organization',
   id     => 'RIR_ORG_ID',
);

$rir_org = $retrieved_objs[0];

unless ($rir_org) {
    die("Get RIR organization object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Get RIR organization successful \n";

$rir_org->maintainer("admin");

$session->modify($rir_org)
   or die("Modify RIR organization failed",
           $session->status_code() . ":" . $session->status_detail());
print "RIR organization modified successfully \n";
```

#Remove RIR organization object

```
@retrieved_objs = $session->get(
   object => 'Infoblox::Grid::RIR::Organization',
   id     => 'RIR_ORG_ID',
);

$rir_org = $retrieved_objs[0];

unless ($rir_org) {
    die("Get RIR organization object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Get RIR organization successful \n";

$session->remove( $rir_org )
    or die("Remove RIR organization failed",
```

```
            $session->status_code() . ":" . $session->status_detail());
print"RIR organization removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::RootNameServer - Custom root name server object.

DESCRIPTION

The custom root name server provides host name and IP address information of internal root name server. When the Infoblox appliance receives a recursive query for DNS data that it does not have, it will use the internal root name server specified, instead of using the internet root name server.

CONSTRUCTOR

```
my $rootns = Infoblox::Grid::RootNameServer->new(
             host_name => $fqdn,      #Required
             ipv4addr  => $ipv4addr   #Required if $ipv6addr is not present
             ipv6addr  => $ipv6addr   #Required if $ipv4addr is not present
);
```

MODULE METHODS

The following functions are available to be applied to a custom root name server object.

Infoblox::Grid::DNS->rootNS( )

Use this function to specify custom root name servers at the grid level on Infoblox appliance. See Infoblox::Grid::DNS->rootNS() for parameters and return values.

Example

```
#Construct a custom root name server object
my $rootns1 = Infoblox::Grid::RootNameServer->new(
             host_name => "qe.infoblox.com",
             ipv4addr  => "1.1.1.1"
);

#Construct a custom root name server object
my $rootns2 = Infoblox::Grid::RootNameServer->new(
             host_name => "doc.infoblox.com",
             ipv6addr  => "2006::132"
);

# Configure custom root name server on the grid DNS object
my $response = $Grid_DNS->rootNS([$rootns1, $rootns2]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a custom root name server.

host_name( )

Use this method to set or retrieve the host name of the custom root name server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the host name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A host name can have a maximum of 256 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get host name
my $host_name = $rootns->host_name();
#Modify host name
$rootns->host_name("qa.infoblox.com");
```

ipv4addr( )

Use this method to set or retrieve the IPv4 address of the custom root name server. Required only when ipv6 is not specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192. 168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $rootns->ipv4addr();
#Modify ipv4addr
$rootns->ipv4addr("2.2.2.2");
```

ipv6addr( )

Use this method to set or retrieve the IPv6 address of the custom root name server. Required only when ipv4 is not specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight groups of four hexadecimal digits separated by colons (example: 12ab:0000:0000:0123:4567:89ab:0000:cdef).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting ipv6addr
my $ipv6addr = $rootns->ipv6addr();
# Modifying ipv6addr
$rootns->ipv6addr("12ab::345");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a custom root name server object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a custom root name server object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;
```

```
#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
              master   => "192.168.1.2", #appliance host ip
              username => "admin",       #appliance user login
              password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a custom root name server object

```
my $rootns = Infoblox::Grid::RootNameServer->new(
             host_name => "qe.infoblox.com",
             ipv4addr  => "1.1.1.1"
);
unless($rootns) {
       die("Construct custom root name server object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Root name server object created successfully\n";
```

#Get the Grid DNS object and add custom root name server to it

```
#Get the Grid DNS object
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DNS",
    grid   => "Infoblox"
);
my $object = $retrieved_objs[0];
unless ($object) {
       die("Get Grid DNS object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get Grid DNS object found at least 1 matching entry\n";

#Apply the changes to the Grid DNS object
$object->rootNS([$rootns]);

#Apply the changes
$session->modify($object)
    or die("Modify Grid DNS object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "Grid DNS object with custom root name server updated to Infoblox appliance successfully\n";
```

#Modify custom root name server

```
#Modify existing custom root name server object

#Modifying the host name of the custom root name server object.
$rootns->host_name("eng.infoblox.com");

#Modifying the IPV4 address of the custom root name server object.
$rootns->ipv4addr("3.3.3.3");

#Apply changes to the Grid DNS object.
$object->rootNS([$rootns]);

#Update Grid DNS object through the Infoblox session.
$session->modify($object)
            or die("modify Grid DNS object failed: ",
                $session->status_code() . ":" . $session->status_detail());
       print "Grid DNS object with modified custom root name server updated to Infoblox appliance
successfully\n";
```

#Remove custom root name server

```
#Apply changes to the Grid DNS object to use default internet root name server.
$object->rootNS(undef);

#Update Grid DNS object through the Infoblox session.
$session->modify($object)
            or die("Remove custom root name server from Grid DNS object failed: ",
                $session->status_code() . ":" . $session->status_detail());
       print "Removed custom root name server from Grid DNS object successfully\n";
```

```
####PROGRAM ENDS####

NAME

Infoblox::Grid::RPZ::ThreatDetails - RPZ ThreatDetails object.

DESCRIPTION

Use this object to fetch ThreatStop details via ThreatStop REST API.

SESSION METHODS

The object does not support any session methods. It is retrieved as a response for Infoblox::Session->get_rpz_threat_details().

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

active( )

Use this method to retrieve the rule status whether it is active or not. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get active
my $active = $rpz_threat_details->active();
```

danger_level( )

Use this method to retrieve the value of a danger level. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get danger_level
my $danger_level = $rpz_threat_details->danger_level();
```

description( )

Use this method to retrieve the description. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get description
my $description = $rpz_threat_details->description();
```

first_identified( )

Use this method to retrieve the timestamp when the threat was first identified. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get first_identified
my $first_identified = $rpz_threat_details->first_identified();
```

known( )

Use this method to retrieve the rule status whether it is known or not. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get known
my $known = $rpz_threat_details->known();
```

last_seen( )

Use this method to retrieve the timestamp when the threat was last seen. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get last_seen
my $last_seen = $rpz_threat_details->last_seen();
```

name( )

Use this method to retrieve the threat name. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get name
my $name = $rpz_threat_details->name();
```

public_description( )

Use this method to retrieve the threat public description. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get public_description
my $public_description = $rpz_threat_details->public_description();
```

short_description( )

Use this method to retrieve the threat short description. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get short_description
my $short_description = $rpz_threat_details->short_description();
```

NAME

Infoblox::Grid::ScheduledBackup - Scheduled Backup object.

DESCRIPTION

The Scheduled Backup object is used to schedule system backups.

CONSTRUCTOR

```
 #Constructor for a ScheduledBackup object
 my $backup = Infoblox::Grid::ScheduledBackup->new (
         backup_type => "LOCAL" | "TFTP" | "FTP" | "SCP",    #Optional / Default is "LOCAL"
         keep_local_copy  => "true" | "false",               #Optional / Default is "false"
         backup_frequency => "Weekly" | "Daily" | "Hourly", #Optional / Default is "Daily"
         weekday => "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "Sunday" | "Monday" | "Tuesday" |
"Wednesday" | "Thursday" | "Friday" | "Saturday"  #Optional / Default is "0"
         hour_of_day      => $num,                           #Optional / Default is 3
         minute_of_hour   => $num,                           #Optional / Default is 0
         user             => $string,                        #Optional / Default is undefined
         password         => $string,                        #Optional / Default is undefined
         backup_server    => $string,                        #Optional / Default is undefined
         path             => $string,                        #Optional / Default is undefined
         disabled         => "true" | "false",               #Optional / Default is "false"

         source             => "DB" | "REPORTING"            #Optional / Default is "DB"
         status             => "IDLE" | "TRIGGERED" | "IN_PROGRESS" | "FINISHED" | "FAILED", #Optional /
Default is "IDLE"
         operation_state    => 'TRIGGERED',                  #Optional / Default is undefined
         operation          => "NONE" | "BACKUP" | "RESTORE", #Optional / Default is "NONE"
         restore_type       => "FTP" | "SCP",                #Optional / Default is "FTP"
         restore_host       => $string,                      #Optional / Default is undefined
         restore_username   => $string,                      #Optional / Default is undefined
         restore_password   => $string,                      #Optional / Default is undefined
         restore_directory  => $string,                      #Optional / Default is undefined
         nios_data          => 'true' | 'false',             #Optional / If any of nios_data and
discovery_data is not
                                                             #defined, nios_data is 'true'.
```

```
        discovery_data    => 'true' | 'false',              #Optional / If any of nios_data and
discovery_data is not
                                                            #defined, discovery_data is 'false'.
        splunk_app_data   => 'true' | 'false',              #Optional / Default is 'false'
         );
```

MODULE METHODS

The following functions can be applied to a ScheduledBackup object.

Infoblox::Grid->scheduled_backup( )

Use this function to specify a ScheduledBackup object. See Infoblox::Grid->scheduled_backup() for parameters and return values.

Example

```
# Retrieve the list of ScheduledBackup objects from the Grid object.
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid",
    name   => "Infoblox"
);

my $Grid_obj = $retrieved_objs[0];

# construct a ScheduledBackup object
my $backup = Infoblox::Grid::ScheduledBackup->new (
    backup_type => "LOCAL",
    backup_frequency => "Weekly",
    weekday => "0", # "0" is the same as "Sunday"
    hour_of_day => "4",
    minute_of_hour => "0",
    user  => "username",
    password => "user-password",
    backup_server  => "my-backup-server",
    path => "/tmp/infoblox/database.tar.gz",
    disabled => "false",
);

# Modify the scheduled backup list
$Grid_obj->scheduled_backup($backup);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a ScheduledBackup object.

backup_type( )

Use this method to set or retrieve the destination of the backup files. You can back up system files to a local directory, a TFTP server, an FTP server, or an SSH server that supports SCP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "LOCAL", "TFTP", "FTP" or "SCP". The default value is "LOCAL".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get backup_type
my $backup_type = $backup->backup_type();
#Modify backup_type
$backup->backup_type("FTP");
```

keep_local_copy( )

Use this method to control whether a local backup is created in addition to a remote one. This option works only if you also specify a remote backup type (TFTP, FTP, or SCP). You cannot enable this option using the "LOCAL" backup type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "true" and "false". The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get keep_local_copy
my $keep_local_copy = $backup->keep_local_copy();
#Modify keep_local_copy
$backup->backup_type("true");
```

backup_frequency( )

Use this method to set or retrieve the frequency of backups.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "Weekly", "Daily" or "Hourly". The default value is "Daily".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get backup frequency
my $backup_backup_frequency = $backup->backup_frequency();
#Modify backup frequency
$backup->backup_frequency("Weekly");
```

weekday( )

Use this method to set or retrieve the day of the week when the backup is performed. This is required only when backup_frequency is set to "Weekly".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "0", "1", "2", "3", "4", "5", "6", "7", "Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday" or "Saturday". "0" means "Sunday", "1" - "Monday". etc. The default value is "6" (Saturday).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get weekday
my $weekday = $backup->weekday();
#Modify weekday
$backup->weekday("0");
```

execute( )

Use this method to set the state for Reporting scheduled backup / restore operation. This is a write-only attribute.

Parameter

The valid value is 'TRIGGER'. The default is undefined.

Returns

None

Example

```
#Modify operation_state value
$object->execute('TRIGGER');
```

hour_of_day( )

Use this method to set or retrieve the hour when the backup is performed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number from 0 through 23. The default value is 3 (3:00 A.M.).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get hour_of_day
my $hour_of_day = $backup->hour_of_day();
#Modify hour_of_day
$backup->hour_of_day("4");
```

minute_of_hour( )

Use this method to set or retrieve the minute of the hour when the backup is performed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number from 0 through 59. The default value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get minute_of_hour
my $minute_of_hour = $backup->minute_of_hour();
#Modify minute_of_hour
$backup->minute_of_hour("5");
```

nios_data( )

Use this method to enable or disable the backup and restore of NIOS data.

If any of nios_data and discovery_data is not defined, nios_data is 'true'.

Parameter

Set the parameter to "true" to enable backup/restore of NIOS data. Set the parameter to "false" to disable the object. The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nios_data
my $nios_data = $backup->nios_data();
#Modify nios_data
$backup->nios_data("true");
```

discovery_data( )

Use this method to enable or disable the backup and restore of Network Automation data.

If any of nios_data and discovery_data is not defined, discovery_data is 'false'.

Parameter

Set the parameter to "true" to enable backup/restore of Network Automation data. Set the parameter to "false" to disable the object. The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_data
my $nios_data = $backup->discovery_data();
#Modify discovery_data
$backup->discovery_data("true");
```

splunk_app_data( )

Use this method to enable or disable the backup and restore of Splunk application data.

Parameter

Set the parameter to "true" to enable backup/restore of Splunk application data. Set the parameter to "false" to disable the object. The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get splunk_app_data
my $nios_data = $backup->splunk_app_data();
#Modify splunk_app_data
$backup->splunk_app_data("true");
```

user( )

Use this method to set or retrieve the user name on the backup server. This is required only when backup_type is set to "FTP" or "SCP".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The user name in string format with a maximum of 1024 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get user
my $user = $backup->user();
#Modify user
$backup->user("admin1");
```

password( )

Use this method to set the user password on the backup server. This is required only when backup_type is set to "FTP" or "SCP". This is a write-only attribute.

Parameter

The password in string format with a maximum of 64 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify password
$backup->password("userpassword");
```

backup_server( )

Use this method to set or retrieve the IP address of the backup server. This is required only when backup_type is set to "FTP", "TFTP" or "SCP".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The IP address of the backup server.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get backup_server
my $backup_server = $backup->backup_server();
#Modify backup_server
$backup->backup_server("my-backup-server");
```

path( )

Use this method to set or retrieve the directory path to the backup file stored on the server. This is required only when backup_type is set to "FTP" or "SCP".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired path in string format with a maximum of 1024 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get path
my $path = $backup->path();
#Modify path
$backup->path("/tmp/infoblox/database.tar.gz");
```

disabled( )

Use this method to disable the ScheduledBackup object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to disable the ScheduledBackup object. Set the parameter to "false" to enable the object. The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disabled
my $disabled = $backup->disabled();
#Modify disabled
$backup->disabled("true");
```

source( )

Use thi method to set or retrieve the source of ScheduledBackup object.

Parameter

Can be set to "DB" to operate with Grid ScheduledBackup object or to "REPORTING" to operate with Reporting ScheduledBackup object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get source
my $source = $backup->source();
#Modify source
$backup->source("REPORTING");
```

status( )

Use this method to set or retrieve the status of the Reporting ScheduledBackup object.

Parameter

Either "TRIGGERED" or "IN_PROGRESS" to identify that Reporting backup/restore is running. Status "FINISHED" means Reporting backup/restore succeeded. Status "FAILED" means Reporting backup/restore failed. The default value of this parameter is "IDLE".

Set status to "TRIGGERED" to run a Reporting manual backup. Use this for a Reporting manual backup only.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get status
my $status = $backup->status();
#Modify status
$backup->status("TRIGGERED");
```

operation( )

Use this method to set or retrieve the operation of the Reporting ScheduledBackup object.

Parameter

Specify "BACKUP" to indicate that a Reporting backup must be performed, or specify "RESTORE" to indicate that a Reporting restore must be performed. The default value is "NONE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get operation
my $operation = $backup->operation();
#Modify operation
$backup->operation("RESTORE");
```

restore_type( )

Use this method to set or retrieve the destination of the restore files when the operation is set to "RESTORE". You can back up system files to an FTP server, or an SSH server that supports SCP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "FTP" or "SCP". The default value is "FTP".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get restore_type
my $restore_type = $backup->restore_type();
#Modify restore_type
$backup->restore_type("FTP");
```

restore_host( )

Use this method to set or retrieve the IP address of the restore server when the operation is set to "RESTORE".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The IP address of the restore server.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get backup_server
my $restore_host = $backup->restore_host();
#Modify restore_host
$backup->restore_host("my-restore-server");
```

restore_username( )

Use this method to set or retrieve the user name that is used to log in to the restore server. This is required only when "RESTORE" operation is performed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The user name in string format with a maximum of 1024 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get user
my $restore_username = $backup->restore_username();
#Modify user
$backup->restore_username("admin1");
```

restore_password( )

Use this method to set the user password that is used to log in to the restore server. This is required only when "RESTORE" operation is performed. This is a write-only attribute.

Parameter

The restore_password in string format with a maximum of 64 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify restore_password
$backup->restore_password("userpassword");
```

restore_directory( )

Use this method to set or retrieve the directory path to the restored file on the server. This is required only when "RESTORE" operation is performed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired path in string format with a maximum of 1024 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get restore_directory
my $restore_directory = $backup->restore_directory();
#Modify restore_directory
$backup->restore_directory("/tmp");
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to an object such as create, modify, and remove an object. This sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Add a ScheduledBackup object

```
my @result_array = $session->get( "object" => "Infoblox::Grid", "name" => "Infoblox");
if( scalar( @result_array ) > 0 )
 {
        my $Grid_obj = $result_array[0];
        unless ($Grid_obj) {
                die("Get Grid object failed: ",
        $session->status_code() . ":" . $session->status_detail());
        }
        # construct a ScheduledBackup object
        my $backup = Infoblox::Grid::ScheduledBackup->new (
            backup_type => "LOCAL",
            backup_frequency => "Weekly",
            weekday => "0", # "0" is the same as "Sunday"
            hour_of_day => "4",
            minute_of_hour => "0",
            user  => "username",
            password => "user-password",
            backup_server  => "10.0.3.4",
            path => "/tmp/infoblox/database.tar.gz",
            disabled => "false",
        );

        # Add ScheduledBackup to Grid object.
        $Grid_obj->scheduled_backup($backup);

        $session->modify($Grid_obj)
            or die("Modify Grid failed: ",$session->status_code(). ":" .$session->status_detail());
        print "ScheduledBackup added to Grid object sucessfully\n";
         } else {
             print "No Grid object found.";
         }
```

#Modify an existing ScheduledBackup object

```
@result_array = $session->get( "object" => "Infoblox::Grid", "name" => "Infoblox");
if( scalar( @result_array ) > 0 )
```

```
{
        my $Grid_obj = $result_array[0];
        unless ($Grid_obj) {
                die("Get Grid object failed: ",
        $session->status_code() . ":" . $session->status_detail());
        }

         # get ScheduledBackup from Grid object.
         my $backup= $Grid_obj->scheduled_backup();

         #modify the backup frequency
         $backup->backup_frequency("Daily");

         # Add ScheduledBackup to Grid object.
         $Grid_obj->scheduled_backup($backup);

         $session->modify($Grid_obj)
            or die("Modify Grid failed: ",$session->status_code(). ":" .$session->status_detail());
         print "ScheduledBackup modified on Grid object sucessfully\n";
          } else {
              print "No Grid object found.";
          }
```

#Remove an existing ScheduledBackup object

```
@result_array = $session->get( "object" => "Infoblox::Grid", "name" => "Infoblox");
if( scalar( @result_array ) > 0 )
 {
        my $Grid_obj = $result_array[0];
        unless ($Grid_obj) {
                die("Get Grid object failed: ",
        $session->status_code() . ":" . $session->status_detail());
        }

         # empty ScheduledBackup list on Grid object.
         $Grid_obj->scheduled_backup([]);

         $session->modify($Grid_obj)
            or die("Modify Grid failed: ",$session->status_code(). ":" .$session->status_detail());
         print "ScheduledBackup removed on Grid object sucessfully\n";
          } else {
              print "No Grid object found.";
          }

####PROGRAM ENDS####

NAME

Infoblox::Grid::ScheduledTask - scheduled task object.

DESCRIPTION

A scheduled task object is used to retrieve information about scheduled tasks. Scheduled tasks are commands that are scheduled by the Infoblox::Session methods, Infoblox::Session->add(), Infoblox::Session->modify() and Infoblox::Session->remove(), and are called with the scheduled_at parameter.

CONSTRUCTOR

The Infoblox::Grid::ScheduledTask object is automatically generated after the Infoblox::Session methods, Infoblox::Session->add(), Infoblox::Session->modify() and Infoblox::Session->remove(), are called with the scheduled_at parameter. It does not require manual construction.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a scheduled task object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

Apply the following attributes to get a specific scheduled task object:

member - The Grid member name.

scheduled_time - The time when the task is scheduled to occur.

submit_time - The time when the scheduled task was submitted.

submitter - The name of the user who submitted the task (regular expression).

task_id - The identifier of a scheduled task.

action - The type of action performed. When used, the search returns ScheduledTask objects that have ScheduledTask::ChangedObject objects in the changed_objects list with matching 'action' attributes. Possible values are:

```
Add
Modify
Delete
Network Discovery
Restart Services
```

object_name - The name of the changed object (regular expression). When used, the search returns ScheduledTask objects that have ScheduledTask::ChangedObject objects in the changed_objects list with matching 'object_name' attirbutes.

object_type - The type of the changed object (regular expression). When used, the search returns ScheduledTask objects that have ScheduledTask::ChangedObject objects in the changed_objects list with matching 'object_type' attributes. Possible values are:

```
A Record
AAAA Record
Authoritative Zone
Bulk Host
CNAME Record
Delegated Zone
DHCP Range
DNAME Record
DNS View
Fixed Address
Forward Zone
Host Record
IPv4 Network
IPv4 Network Container
IPv6 Network
IPv6 Network Container
MX Record
NS Record
PTR Record
Reservation
Roaming Host
Shared A Record
Shared AAAA Record
Shared MX Record
Shared Network
Shared Record Group
Shared SRV Record
Shared TXT Record
SRV Record
Stub Zone
TXT Record
```

Example

```
my @retrieved_objs = $session->get(
    object     => "Infoblox::Grid::ScheduledTask",
    task_id    => "34" );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the object.
$task->scheduled_time( "2008-10-21T10:56:33Z" );
# Submit modification
my $response = $session->modify( $task );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, use `get()` or `search()` to retrieve the specific object first, and then submit this object for removal.

Example

```
# Get the ScheduledTask objects
my @retrieved_objs = $session->get(
    object     => "Infoblox::Grid::ScheduledTask",
    submitter  => "admin" );
# find the desired object from the retrieved list.
```

```
my $task = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $task );
```

Infoblox::Session->search( )

Use this method to search for scheduled task objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

The search can be performed on any combination of the following attributes:

member - The Grid member name.

scheduled_time - The time when the task is scheduled to occur. This method supports searching with limit parameters (see below).

submit_time - The time when the scheduled task was submitted. This method supports searching with limit parameters (see below).

submitter - The name of the user who submitted the task (regular expression).

task_id - The identifier of a scheduled task.

action - The type of action performed. When used, the search returns ScheduledTask objects that have ScheduledTask::ChangedObject objects in the changed_objects list with matching 'action' attributes. Possible values are:

```
Add
Modify
Delete
Network Discovery
Restart Services
```

object_name - The name of the changed object (regular expression). When used, the search returns ScheduledTask objects that have ScheduledTask::ChangedObject objects in the changed_objects list with matching 'object_name' attirbutes.

object_type - The type of the changed object (regular expression). When used, the search returns ScheduledTask objects that have ScheduledTask::ChangedObject objects in the changed_objects list with matching 'object_type' attributes. Possible values are:

```
A Record
AAAA Record
Authoritative Zone
Bulk Host
CNAME Record
Delegated Zone
DHCP Range
DNAME Record
DNS View
Fixed Address
Forward Zone
Host Record
IPv4 Network
IPv4 Network Container
IPv6 Network
IPv6 Network Container
MX Record
NS Record
PTR Record
Reservation
Roaming Host
Shared A Record
Shared AAAA Record
Shared MX Record
Shared Network
Shared Record Group
Shared SRV Record
Shared TXT Record
SRV Record
Stub Zone
TXT Record
```

See Infoblox::Session/search with limit parameters for more information on this functionality.

Example

```
# search for all ScheduledTask objects
my @retrieved_objs = $session->search(
    object  => "Infoblox::Grid::ScheduledTask",
    scheduled_time => ">=< 2008-10-21T10:56:33Z,2008-11-21T10:56:33Z");
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a ScheduledTask object.

approval_status( )

Use this method to set or retrieve the approval status if approvals are required for this task.

Parameter

Valid values are 'NONE', 'APPROVED', 'PENDING' and 'REJECTED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get approval_status value
my $approval_status = $task->approval_status();

#Modify approval_status value
$task->approval_status('APPROVED');
```

approver( )

Use this method to retrieve the username of the approver. This is a read-only attribute.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get approver value
my $approver = $task->approver();
```

approver_comment( )

Use this method to set or retrieve the approver comment.

Parameter

The approver comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get approver_comment value
my $approver_comment = $task->approver_comment();

#Modify approver_comment value
$task->approver_comment('ok');
```

changed_objects( )

Use this method to retrieve information about the objects that are scheduled to be changed.

Parameter

none

Returns

The method returns a reference to an array of Infoblox::Grid::ScheduledTask::ChangedObject objects.

Example

```
#Get changed_objects
my $changed_objects = $task->changed_objects();
my $obj = $changed_objects->[0];
```

dependent_tasks( )

Use this method to retrieve an array of of tasks dependent on this one. This is a read-only attribute.

Parameter

None

Returns

The method returns a reference to an array of Infoblox::Grid::ScheduledTask objects.

Example

```
#Get array of ScheduledTask objects
my @dependent_tasks = $task->dependent_tasks();
```

execution_details( )

Use this method to retrieve the list of details generated by the execution. This is a read-only field.

Parameters

None

Returns

The method returns the array of strings that contains details generated by the execution.

Example

```
#Get execution_details value
my $details = $task->execution_details();
```

execution_details_type( )

Use this method to retrieve the type of details generated by the execution after the task has been completed. This is a read-only field.

Parameters

None

Returns

The method returns the attribute value that can be 'NONE' or 'WARNING'.

Example

```
#Get execution_details_type value
my $details = $task->execution_details_type();
```

execution_status( )

Use this method to retrieve the status of the task. This is a read-only attribute.

Parameter

none

Returns

The method returns the attribute value that can be 'COMPLETED', 'FAILED' or 'PENDING'.

Example

```
#Get execution_status
my $execution_status = $task->execution_status();
```

execution_time( )

Use this method to retrieve the execution time. This is a read-only attribute.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get execution_time
my $execution_time = $task->execution_time();
```

member( )

Use this method to retrieve the Grid member that has created this task. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get member
my $member = $task->member();
```

is_network_insight_task( )

Use this method to retrieve the flag that indicates if this task is related to network insight. This is a read-only attribute.

Parameter

none

Returns

This method returns the attribute value.

Example

```
#Get value
$value = $task->is_network_insight_task();
```

re_execute_task( )

Use this method to set failed discovery task to be re-executed.

If this flag is set to 'true' a failed Network Insight discovery task will be re-executed, a new task will be created cloned from this one and restarted.

Parameter

Boolean to set failed netmri task to be re-executed. Only "true" value makes sense.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get value
$value = $task->re_execute_task();

# Set value
$task->re_execute_task('true');
```

scheduled_time( )

Use this method to set or retrieve the date and time the task is scheduled to occur.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Scheduled date and time in ISO 8601 extended format (e.g., 2008-10-21T10:56:33Z or 2008-10-21T10:56:33.001Z).

Use case insensitive value "now" to execute a scheduled task immediately.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get scheduled_time value
my $scheduled_time = $task->scheduled_time();

#Modify scheduled_time value
$task->scheduled_time("2008-10-21T10:56:33Z");
# Submit modification
$session->modify($task);

# Do it now
$task->scheduled_time("Now");
# Submit modification
$session->modify($task);
```

submit_time( )

Use this method to retrieve the time the scheduled task was submitted (when appropriate Session method was called with parameter scheduled_time).

Parameter

none

Returns

The method returns the submitted date and time in ISO 8601 extended format (e.g., 2008-10-21T10:56:00Z or 2008-10-21T10:56:00.001Z).

Example

```
#Get submit_time
my $submit_time = $task->submit_time();
```

submitter_comment( )

Use this method to set or retrieve the submitter comment.

Parameter

The submitter comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get submitter_comment value
my $submitter_comment = $task->submitter_comment();

#Modify submitter_comment value
$task->submitter_comment('ok');
```

submitter( )

Use this method to retrieve the name of the user who submitted the task.

Parameter

none

Returns

The method returns the user name in string format.

Example

```
#Get submitter
my $submitter = $task->submitter();
```

task_id( )

Use this method to retrieve the identifier of a scheduled task.

Parameter

none

Returns

The method returns the identifier in numeric format.

Example

```
#Get task_id
my $task_id = $task->task_id();
```

ticket_number( )

Use this method to set or retrieve the ticket number.

Parameter

The ticket number in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ticket_number value
my $ticket_number = $task->ticket_number();

#Modify ticket_number value
$task->ticket_number('ok');
```

task_type( )

Use this method to retrieve the scheduled task type. This is a read-only attribute.

Parameter

none

Returns

The method returns the attribute value. Valid return value is "OBJECT_CHANGE" and "PORT_CONTROL".

Example

```
#Get task_type value
my $task_type = $task->task_type();
```

time_zone( )

Use this method to set or retrieve the time zone.

Parameter

The UTC string that represents the time zone. For example "(UTC - 6:00) Central Time (US and Canada)". The default value is "(UTC) Coordinated Universal Time".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->time_zone();

#Modify attribute value
$schedule_setting->time_zone("(UTC - 6:00) Central Time (US and Canada)");
```

predecessor_task( )

Use this method to retrieve the predecessor task. This is a read-only attribute.

Parameter

none

Returns

The method returns an Infoblox::Grid::ScheduledTask object.

Example

```
#Get predecessor_task value
my $predecessor_task = $task->predecessor_task();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a ScheduledTask object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
               );

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

# Add a network
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/24",
);
unless ($network) {
    die("Construct Network failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network created successfully\n";

$session->add($network)
    or die("Add Network object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "Network object added to server successfully\n";
```

#Create a ScheduledTask object

```
# Create a fixed address
my $fixed_addr = Infoblox::DHCP::FixedAddr->new(
    ipv4addr    => '10.0.0.3',
    mac         => '11:22:33:44:55:66'
);
unless ($fixed_addr) {
    die("Construct FixedAddr failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "FixedAddr created successfully\n";

# Schedule the addition of a fixed address
$session->add($fixed_addr, scheduled_at => "2020-01-01T14:52:00Z")
    or die("Schedule fixed address add failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "Fixed address add scheduled successfully\n";
```

#Search for a ScheduledTask object

```
my @retrieved_objs = $session->search(
    object    => "Infoblox::Grid::ScheduledTask",
    submitter => "admin"
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Search for a ScheduledTask object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search for a ScheduledTask object found at least 1 matching entry\n";
```

#Get and modify a ScheduledTask object

```
#Get the ScheduledTask object from Infoblox appliance through a session
my @retrieved_objs = $session->get(
    object         => "Infoblox::Grid::ScheduledTask",
    scheduled_time => "2020-01-01T14:52:33Z"
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Get ScheduledTask object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get ScheduledTask object found at least 1 matching entry\n";

#Modify the ScheduledTask object
$object->scheduled_time("2020-02-01T14:52:33Z");

#Apply the changes.
$session->modify($object)
    or die("Modify ScheduledTask object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "ScheduledTask object modified successfully \n";
```

#Remove a ScheduledTask object

```
#Get the ScheduledTask object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::ScheduledTask",
    action => "Add"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get ScheduledTask object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get ScheduledTask object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove ScheduledTask object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "ScheduledTask object removed successfully \n";
```

#Cleanup

```
#Get the Network object through the session
my @retrieved_objs = $session->get(
    object  => "Infoblox::DHCP::Network",
    network => "10.0.0.0/24"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get Network object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Network object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove Network object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "Network object removed successfully \n";
```

```
####PROGRAM ENDS####
```

SCHEDULED DATE AND TIME FORMAT

Scheduled date and time are represented in ISO 8601 extended format (e.g., 2008-10-21T10:56:00Z or 2008-10-21T10:56:00.001Z) with some restrictions:

- Maximal value for year field is 2037.

When the scheduling parameter is used, changes to objects do not occur immediately. Instead, the Infoblox::Grid::ScheduledTask object is created, and then executed at the time specified in this parameter.

NAME

Infoblox::Grid::ScheduledTask::ChangedObject - Scheduled Task Changed Object.

DESCRIPTION

A Scheduled Task Changed Object is used to retrieve information about objects with changes that were scheduled in Infoblox::Grid::ScheduledTask.

CONSTRUCTOR

The Infoblox::Grid::ScheduledTask::ChangedObject is a read-only object and does not require manual construction.

MODULE METHODS

The following functions can be applied to a ChangedObject object.

Infoblox::Grid::ScheduledTask->changed_objects( )

Use this function to retrieve the changed objects list. See Infoblox::Grid::ScheduledTask->changed_objects() for parameters and return values.

Example

```
# Retrieve the list of ScheduledTask objects
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::ScheduledTask",
    submitter => "admin" );

my $task = $retrieved_objs[0];

# get ChangedObject
my $changed_objects = $task->changed_objects();
my $obj = $changed_objects->[0];
```

METHODS

This section describes all the methods that you can use to retrieve the attribute values of a ChangedObject object.

action( )

Use this method to retrieve the operation performed on the objects.

Parameter

none

Returns

The method returns the operation in string format. Possible values are:

"Network Discovery" for network_discovery_control( ) service,

"Restart Services" for restart( ) services,

"Add", "Modify", "Delete" for all other objects.

Example

```
#Get action
my $action = $changed_object->action();
```

changed_properties( )

Use this method to retrieve the list of changed properties in the object.

Parameter

none

Returns

The method returns a reference to an array of strings. Each string in the array describes the changes. The descriptions are similiar to the entries in the Change Audit Log column in the GUI.

Example

```
#Get changed_properties value
my $changed_properties = $changed_object->changed_properties();
for (@$changed_properties) {
    print $_,"\n";
}
```

object_name( )

Use this method to retrieve the name of the changed object.

Parameter

none

Returns

The method returns the object name in string format.

Example

```
#Get object_name
my $object_name = $changed_object->object_name();
```

object_type( )

Use this method to retrieve the type of the changed object.

Parameter

none

Returns

The method returns an object type in string format, such as "A Record" or "Shared TXT Record".

Example

```
#Get object_type
my $object_type = $changed_object->object_type();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a ScheduledTask object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
```

```
my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
               );

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/24",
);
unless ($network) {
    die("Construct Network failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network created successfully\n";

$session->add($network)
    or die("Add Network object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "Network object added to server successfully\n";
```

#Create a ScheduledTask object

```
# Create a fixed address
my $fixed_addr = Infoblox::DHCP::FixedAddr->new(
    ipv4addr    => '10.0.0.3',
    mac         => '11:22:33:44:55:66'
);
unless ($fixed_addr) {
    die("Construct FixedAddr failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "FixedAddr created successfully\n";

# Schedule the addition of a fixed address
$session->add($fixed_addr, scheduled_at => "2020-01-01T14:52:00Z")
    or die("Schedule fixed address add failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "Fixed address add scheduled successfully\n";
```

#Search for a ScheduledTask

```
my @retrieved_objs = $session->search(
    object    => "Infoblox::Grid::ScheduledTask",
    submitter => "admin"
);

NAME

Infoblox::Grid::ScheduleSetting - a schedule setting object.

DESCRIPTION

An object that provides the ability to set the schedule for a discovery task.

CONSTRUCTOR

```
my $schedule_setting = Infoblox::Grid::ScheduleSetting->new(
   frequency           => "DAILY" | "HOURLY" | "MONTHLY" | "WEEKLY",      # optional
   day_of_month        => $uint,                                          # optional
   every               => $uint,                                          # optional
   weekdays            => ["MONDAY", "THURSDAY", .... ],                  # optional
   hour_of_day         => $uint,                                          # optional
   minutes_past_hour   => $uint,                                          # optional
   month               => $uint,                                          # optional
   year                => $uint,                                          # optional
   repeat              => "ONCE" | "RECUR",                               # optional
   disable             => "true" | "false",                               # optional
   time_zone           => $time_zone,                                     # optional
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to configure and retrieve attribute values of the scheduling object.

day_of_month( )

Use this method to set or retrieve the scheduled day of month when the discovery is triggered.

Parameter

Valid value is an unsigned integer between 1-31.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->day_of_month();
#Modify attribute value
$schedule_setting->day_of_month(10);
```

disable( )

Use this method to enable or disable scheduling of a discovery task.

Parameter

Specify "true" to disable scheduling or "false" to enable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->disable();
#Modify attribute value
$schedule_setting->disable("true");
```

every( )

Use this method to set or retrieve the recurrence pattern of a recurring discovery.

Parameter

Valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->every();
#Modify attribute value
$schedule_setting->every(2);
```

frequency( )

Use this method ot set or retrieve the recurrence pattern of a recurring discovery.

Parameter

Valid value is "DAILY", "HOURLY", "MONTHLY" or "WEEKLY".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->frequency();
#Modify attribute value
$schedule_setting->frequency("MONTHLY");
```

hour_of_day( )

Use this method to set or retrieve the hour, based on the 24-hour clock notation, when the discovery should start. For example, use 18 for 18:00.

Parameter

Valid value is an unsigned integer between 0-23.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->hour_of_day();
#Modify attribute value
$schedule_setting->hour_of_day(5);
```

month( )

Use this method to set or retrieve the month of the year when the discovery should start. For example, use 1 for January, 2 for February, and so on.

Parameter

Valid value is an unsigned integer between 1 and 12.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->month();
#Modify attribute value
$schedule_setting->month(10);
```

year( )

Use this method to set or retrieve the year when the discovery should start.

Parameter

Valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->year();
#Modify attribute value
$schedule_setting->year(2015);
```

minutes_past_hour( )

Use this method to set or retrieve the minute, based on the 24-hour clock notation, when the discovery should start. For example, use 59 for 00:59.

Parameter

Valid value is an unsigned integer between 0-59.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->minutes_past_hour();
#Modify attribute value
$schedule_setting->minutes_past_hour(10);
```

repeat( )

Use this method to set or retrieve the flag that indicates if the discovery is scheduled for once or recurring.

Parameter

Valid value is "ONCE" or "RECUR".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->repeat();
#Modify attribute value
$schedule_setting->repeat("RECUR");
```

time_zone( )

Use this method to set or retrieve the time zone.

Parameter

The UTC string that represents the time zone. For example "(UTC - 6:00) Central Time (US and Canada)". The default value is "(UTC) Coordinated Universal Time".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->time_zone();
#Modify attribute value
$schedule_setting->time_zone("(UTC - 6:00) Central Time (US and Canada)");
```

weekdays( )

Use this method to set or retrieve the days of the week when the discovery is triggered.

Parameter

Valid value is a reference to an array that can contain the following values: 'SUNDAY', 'MONDAY', 'TUESDAY', 'WEDNESDAY', 'THURSDAY', 'FRIDAY' and 'SATURDAY'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $schedule_setting->weekdays();
#Modify attribute value
$schedule_setting->weekdays(["MONDAY", "FRIDAY"]);
```

NAME

Infoblox::Grid::ServiceRestart - a Grid Service Restart setting object.

DESCRIPTION

The Grid Service Restart setting object provides information about service restart configurations.

CONSTRUCTOR

```
my $service_restart = Infoblox::Grid::ServiceRestart->new(
   delay           => $uint,              # Optional / Default is 10
   restart_offline => 'true' | 'false', # Optional / Default is 'true'
   timeout         => $int,               # Optional / Default is 60
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions are available to apply to a Grid Service Restart object.

Infoblox::Grid::DNS->restart_setting( )

Use this method to set or retrive Grid DNS service restart settings. See Infoblox::Grid::DNS->restart_setting() for parameters and return values.

Example

```
#Get restart_setting
my $restart_setting = $grid_dns->restart_setting();
#Modify the retry time
$grid_dns->restart_setting($restart_setting);
```

Infoblox::Grid::DHCP->restart_setting( )

Use this method to set or retrive Grid DHCP service restart settings. See Infoblox::Grid::DHCP->restart_setting() for parameters and return values.

Example

```
#Get restart_setting
my $restart_setting = $grid_dns->restart_setting();
#Modify the retry time
$grid_dns->restart_setting($restart_setting);
```

METHODS

delay( )

Use this method to set or retrieve restart delay in seconds between Grid Service Groups.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer. The default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get delay
my $delay = $svcrst->delay();
#Modify delay
$svcrsts->delay(50);
```

restart_offline( )

Use this method to enable or disable the restart of offline Grid Members.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the restart of offline Grid Services or 'false' to disable it. The default value is 'true'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get restart_offline
my $restart_offline = $svcrst->restart_offline();
#Modify restart_offline
$svcrsts->restart_offline('false');
```

timeout( )

Use this method to set or retrieve timeout interval in seconds for Grid Service Groups restart.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an integer greater or equal to -1 (where -1 means infinite). The default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get timeout
my $timeout = $svcrst->timeout();
#Modify timeout
$svcrst->timeout(50);
```

NAME

Infoblox::Grid::ServiceRestart::Group - a Grid Service Restart Group object.

DESCRIPTION

The Grid Service Restart Group object provides information about restart of particular services and members, their order and periodicity.

CONSTRUCTOR

```
 my $svcrst_group = Infoblox::Grid::ServiceRestart::Group->new(
    name                  => $string,                                                  #
Required
    service               => 'DHCP' | 'DNS',                                           #
Required
    comment               => $string,                                                  #
Optional / Default is undefined
    mode                  => 'SIMULTANEOUS' | 'SEQUENTIAL',                            #
Optional / Default is
                                                                                       #
'SEQUENTIAL' for default restart groups /                                              #
'SIMULTANEOUS' for non-default restart groups
    members               => $string_array,                                            #
Optional / Default is undefined
    recurring_schedule    => $svcrst_schedule,                                         #
Optional / Default is undefined
    extattrs              => { $string => $extattr, ... },                             #
Optional / Default is undefined
    extensible_attributes => { $string => $string | $num, $string => [ $string | $num, ... ], ... } #
Optional / Default is undefined
 );
```

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a Grid Service Restart Group object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $svcrst_group = Infoblox::Grid::ServiceRestart::Group->new(
   name    => 'test_group',
   service => 'DHCP',
);

#Submit for addition
my $response = $session->add($svcrst_group);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

  comment               - Optional. A Grid Service Restart Group comment.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference that contains extensible attributes.
  is_default            - Optional. Flag which indicates whether the Grid Service Restart Group is a
default restart group or not.
  name                  - Optional. A Grid Service Restart Group name.
  position              - Optional. A Grid Service Restart Group position in Restart Service Order
object.
  service               - Optional. A Grid Service Restart Group service name.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::ServiceRestart::Group',
    name   => 'test_group',
);

my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::ServiceRestart::Group',
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the comment.
$svcrst_group->comment('this is a modified comment');
#Submit modification
my $response = $session->modify($svcrst_group);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::ServiceRestart::Group',
    name   => 'svcrst_group1',
);
#Find the desired object from the retrieved list.
my $desired_svcrst_group = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove($desired_svcrst_group);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

  comment               - Optional. A Grid Service Restart Group comment.
  extattrs              - Optional. A hash reference containing extensible attributes.
```

```
  extensible_attributes - Optional. A hash reference that contains extensible attributes.
  is_default            - Optional. Flag which indicates whether the Grid Service Restart Group is a
default restart group or not.
  name                  - Optional. A Grid Service Restart Group name.
  position              - Optional. A Grid Service Restart Group position in Restart Service Order
object.
  service               - Optional. A Grid Service Restart Group service name.
```

Example

```
my @retrieved_objs = $session->search(
    object => 'Infoblox::Grid::ServiceRestart::Group',
    name   => 'svcrst.*',
);

my @retrieved_objs = $session->search(
    object => 'Infoblox::Grid::ServiceRestart::Group',
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

comment( )

Use this method to set or retrieve Grid Service Restart Group object comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $svcrst_group->comment();
#Modify comment
$svcrst_group->comment(50);
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Grid Service Restart Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get extattrs value
my $ref_extattrs = $svcrst_group->extattrs();

#Modify extattrs
$svcrst_group->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a Grid Service Restart Group object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $svcrst_group->extensible_attributes();

#Modify extensible attributes
$svcrst_group->extensible_attributes({'Site' => 'Santa Clara', 'Administrator' => ['Peter',
'Tom']});
```

is_default( )

Use this method to retrieve the flag which indicates whether the Grid Service Restart Group is a default group or not. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get is_default
my $is_default = $svcrst_group->is_default();
```

last_updated_time( )

Use this method to retrieve time of the last restart of the Grid Service Restart Group. This is the read-only attribute.

Omit the parameter tor retrieve the attribute value.

Parameter

None

Returns

The method returns the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_updated_time
my $last_updated_time = $svcrst_group->last_updated_time()
```

members( )

Use this method to set or retrieve Grid Members associated with the Grid Service Restart Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference of desired Grid Members names.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get members
my $members = $svcrst_group->members();
#Modify members
$svcrst_group->members(['foo.com', 'bar.com']);
```

mode( )

Use this method to set or retrieve the restart mode of Grid Members in the Grid Service Restart Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that if the Service Restart Group is a default one, the default value is 'SEQUENTIAL', 'SIMULTANEOUS' otherwise.

Parameter

The valid values are 'SEQUENTIAL' and 'SIMULTANEOUS'.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mode
my $mode = $svcrst_group->mode();
#Modify mode
$svcrst_group->mode('SEQUENTIAL');
```

name( )

Use this method to set or retrieve the Grid Service Restart Group name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in a string format.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $svcrst_group->name();
#Modify name
$svcrst_group->name('new_name');
```

position( )

Use this method to retrieve the restart position of the Grid Service Restart Group. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get position
my $position = $svcrst_group->position();
```

recurring_schedule( )

Use this method to set or retrieve the recurring schedule of the Grid Service Restart Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ServiceRestart::Group::Schedule object.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recurring_schedule
my $recurring_schedule = $svcrst_group->recurring_schedule();
#Modify recurring_schedule
$svcrst_group->recurring_schedule($svcrst_sched);
```

requests( )

Use this method to retrieve the array of Grid Service Restart Requests. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an array of Infoblox::Grid::ServiceRestart::Request objects.

Example

```
#Get requests
my $requests = $svcrst_group->requests();
```

service( )

Use this method to set or retrieve the service name for the Grid Service Restart Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is 'DHCP' or 'DNS'.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get service
my $service = $svcrst_group->service();
#Modify service
$svcrst_group->service('DHCP');
```

status( )

Use this method to retrieve the Grid Service Restart Group restart status. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::ServiceRestart::Status object.

Example

```
#Get status
my $status = $svcrst_group->status();
```

NAME

Infoblox::Grid::ServiceRestart::Group::Order - A Grid Service Restart Group Order object.

DESCRIPTION

The Grid Service Restart Group Order object controls the restart order of the Service Restart Group for a particular service ('DHCP' or 'DNS'). To specify a restart order, gather all the groups you want to restart for a particular service and then place the Restart Service Groups in the desired order.

Note that the default groups should be placed at the end of the list.

CONSTRUCTOR

```
my $group_order = Infoblox::Grid::ServiceRestart::Group::Order->new(
    groups => [$group1, $group2, ..., $default_group], #Required
);
```

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a Grid Service Restart Group object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $svcrst_group_order = Infoblox::Grid::ServiceRestart::Group::Order->new(
   groups => [$group1, $group2, $default_group],
);

#Submit for addition
my $response = $session->add($svcrst_group_order);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

groups( )

Use this method to set or retrieve the ordered list for Grid Service Restart Groups.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::ServiceRestart::Group objects.

Note that all groups for the specified service ('DHCP' or 'DNS') are required. Default groups should be placed at the end of the list.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get groups
my $groups = $svcrst_gr_order->groups();
#Modify groups
$svcrst_gr_order->groups([$group1, $group2, $group3]);
```

NAME

Infoblox::Grid::ServiceRestart::Group::Schedule - A Grid Service Restart Group Schedule object.

DESCRIPTION

The Grid Service Restart Group Schedule object provides information about restart service schedule settings for Service Restart Group.

CONSTRUCTOR

```
my $svcrst_schedule = Infoblox::Grid::ServiceRestart::Group::Schedule->new(
   schedule => $schedule,                                  # Required
   services => $array_of_services,                         # Optional / Default is ['ALL']
   mode     => 'GROUPED' | 'SEQUENTIAL' | 'SIMULTANEOUS', # Optional / Default is 'GROUPED'
   force    => 'true' | 'false',                           # Optional / Default is 'false'
);
```

MODULE METHODS

Infoblox::Grid::ServiceRestart::Group->recurring_schedule( )

Use this method to set or retrieve the Grid Service Restart Group Schedule. See Infoblox::Grid::ServiceRestart::Group->recurring_schedule() for parameters and return values.

Example

```
#Get recurring_schedule
my $recurring_schedule = $svcrst_group->recurring_schedule();
#Modify recurring_schedule
$svcrst_group->recurring_schedule($sched);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

services( )

Use this method to set or retrieve the list of services for a scheduled restart for a particular Grid Service Restart Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array which contains following values: 'ALL', 'DNS', 'DHCP', 'DHCPV4', 'DHCPV6'.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get services
my $services = $svcrst_schedule->services();
#Modify services
$svcrst_schedule->services('DHCP');
```

mode( )

Use this method to set or retrieve the service restart mode for a scheduled restart for a particular Grid Service Restart Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'GROUPED', 'SEQUENTIAL' and 'SIMULTANEOUS'.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mode
my $mode = $svcrst_schedule->mode();
#Modify mode
$svcrst_schedule->mode('SEQUENTIAL');
```

force( )

Use this method to set or retrieve the flag that indicates whether a forced scheduled restart will be performed for a particular Grid Service Restart Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to set the flag, and 'false' to unset/deactivate it. The default value is 'false'.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get force
my $force = $svcrst_schedule->force();
#Modify force
$svcrst_schedule->force('true');
```

schedule( )

Use this method to set or retrieve the schedule settings for a particular Grid Service Restart Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ScheduleSetting object.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get schedule
my $schedule = $svcrst_schedule->schedule();
#Modify schedule
$svcrst_schedule->schedule($sched);
```

NAME

Infoblox::Grid::ServiceRestart::Request - A Grid Service Restart Request object.

DESCRIPTION

The Grid Service Restart Request object provides information and statistics about restart service routine of the Restart Service Group.

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a Grid Service Restart Request object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

group  - Optional. A Grid Service Restart Group object.
member - Optional. A Grid Member name or object.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::ServiceRestart::Request',
    group  => $group,
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to search for a specific object:

group  - A Grid Service Restart Group object.
member - A Grid Member name or object.
```

Example

```
my @retrieved_objs = $session->search(
    object => 'Infoblox::Grid::ServiceRestart::Request',
    group  => $group,
```

```
);
```

MODULE METHODS

The following functions are available to apply to a Grid Service Restart Request object.

Infoblox::Grid::ServiceRestart::Group->requests( )

Use this method to retrieve restart requests for the Grid Service Restart Group. This is a read-only attribute. See Infoblox::Grid::ServiceRestart::Group->requests() for parameters and return values.

Example

```
#Get requests
my $requests = $svcrst_group->requests();
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

error( )

Use this method to retrieve error messages for failed restart requests. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get error
my $error = $svcrst_request->error();
```

forced( )

Use this method to retrieve the flag that indicates whether this is force restart request or not. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value

Example

```
#Get forced
my $forced = $svcrst_request->forced();
```

group( )

Use this method to retrieve the Grid Service Restart Group object that is associated with the request. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::ServiceRestart::Group object.

Example

```
#Get group
my $group = $svcrst_request->group();
```

last_updated_time( )

Use this method to retrieve the time when the request status has changed. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_updated_time
my $last_updated_time = $svcrst_request->last_updated_time();
```

member( )

Use this method to retrieve the Grid Member name for the restart. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get member
my $member = $svcrst_request->member();
```

needed( )

Use this method to retrieve the value that indicates whether a restart is required or not. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'UNKNOWN', 'CHECKING', 'YES', 'NO' and 'FAILURE'.

Example

```
#Get needed
my $needed = $svcrst_request->needed();
```

order( )

Use this method to retrieve the restart order for the Grid Service Restart Request. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get order
my $order = $svcrst_request->order();
```

result( )

Use this method to retrieve the result of a service restart for a particular Grid Service Restart Request. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'SUCCESS', 'TIMEOUT', 'FAILURE' and 'NORESTART'.

Example

```
#Get result
my $result = $svcrst_request->result();
```

service( )

Use this method to retrieve the service to restart for a particular Grid Service Restart Request. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'DNS', 'DHCP', 'DHCPV4' and 'DHCPV6'.

Example

```
#Get service
my $service = $svcrst_request->service();
```

state( )

Use this method to retrieve the state of a particular Grid Service Restart Request. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'NEW', 'QUEUED', 'PROCESSING' and 'FINISHED'.

Example

```
#Get state
my $state = $svcrst_request->state();
```

NAME

Infoblox::Grid::ServiceRestart::Request::ChangedObject - A Grid service restart request changed object.

DESCRIPTION

The Grid service restart request changed object provides information about changes that are waiting for the restart.

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a Grid service restart request changed object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

 source  - Infoblox::Grid::ServiceRestartGroup or Infoblox::Grid::Member object.
 service - string that contains service that is waiting for restart. The default value is 'ALL'.
```

Example

```
my @retrieved_objs = $session->get(
    object  => 'Infoblox::Grid::ServiceRestart::Request::ChangedObject',
    service => 'DHCPV6',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to search for a specific object:

 source  - Infoblox::Grid::ServiceRestartGroup or Infoblox::Grid::Member object.
 service - string that contains service that is waiting for changes. The default value is 'ALL'.
```

Example

```
my @retrieved_objs = $session->search(
    object  => 'Infoblox::Grid::ServiceRestart::Request::ChangedObject',
    service => 'DHCPV6',
);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

action( )

Use this method to retrieve the operation on the changed object. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get action value
my $value = $object->action();
```

changed_time( )

Use this method to retrieve the timestamp of the change. This is a read-only attribute.

Parameter

None

Returns

The method returns the number of seconds elapsed since January 1, 1970, in UTC format.

Example

```
#Get changed_time value
my $changed_time = $object->changed_time();
```

changed_properties( )

Use this method to retrieve the list of properties changed in the object. This is a read-only attribute.

Parameter

None

Returns

The method returns a reference to an array of strings. Each string in the array describes the changes. The descriptions are similiar to the entries in the Change Audit Log column in the GUI.

Example

```
#Get changed_properties value
my $changed_properties = $object->changed_properties();
```

object_name( )

Use this method to retrieve the name of the changed object. This is a read-only attribute.

Parameter

none

Returns

The method returns the object name in string format.

Example

```
#Get object_name value
my $value = $object->object_name();
```

object_type( )

Use this method to retrieve the type of the changed object. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get object_type value
my $value = $object->object_type();
```

user_name( )

Use this method to retrieve the user name who have changed the object properties. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get user_name value
my $value = $object->user_name();
```

NAME

Infoblox::Grid::ServiceRestart::Status - A Grid Service Restart Status object.

DESCRIPTION

The Grid Service Restart Status object provides information and statistics about restart service routine of the Grid or Restart Service Group.

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a Grid Service Restart Status object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

parent  - Optional. A Grid Service Restart Group or Grid object.
grouped - Optional. A grouping type of the status which can be either 'GRID' or 'GROUP'.
```

Example

```
my @retrieved_objs = $session->get(
    object  => 'Infoblox::Grid::ServiceRestart::Status',
    parent  => $test_group,
    grouped => 'GROUP',

);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to search for a specific object:

parent  - Optional. A Grid Service Restart Group or Grid object.
grouped - Optional. A grouping type of the status which can be either 'GRID' or 'GROUP'.
```

Example

```
my @retrieved_objs = $session->get(
    object  => 'Infoblox::Grid::ServiceRestart::Status',
    parent  => $test_group,
    grouped => 'GROUP',

);
```

MODULE METHODS

The following functions are available to apply to a Grid Service Restart Status object.

Infoblox::Grid::ServiceRestart::Group->status( )

Use this method to retrieve the Grid Service Restart restart status. This is a read-only attribute. See Infoblox::Grid::ServiceRestart::Group->status() for parameters and return values.

Example

```
#Get status
my $status = $svcrst_group->status();
```

Infoblox::Grid->restart_status( )

Use this method to retrieve the Grid restart status. This is a read-only attribute. See Infoblox::Grid->restart_status() for parameters and return values.

Example

```
#Get status
my $status = $grid->restart_status();
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

failures( )

Use this method to retrieve the number of failed service restart requests. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get failures
my $failures = $svcrst_status->failures();
```

finished( )

Use this method to retrieve the number of completed service restart requests. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get finished
my $finished = $svcrst_status->finished();
```

parent( )

Use this method to retrieve the Grid or Grid Service Restart Group objects. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value can be either Infoblox::Grid or Infoblox::Grid::ServiceRestart::Group object.

Example

```
#Get group
my $group = $svcrst_status->group();
```

grouped( )

Use this method to retrieve the grouping type of the status which can be either 'GRID' or 'GROUP'. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get failures
my $failures = $svcrst_status->failures();
```

needed_restart( )

Use this method to retrieve the number of created but unprocessed restart requests. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get no_restart
my $needed_restart = $svcrst_status->needed_restart();
```

no_restart( )

Use this method to retrieve the number of service restarts that are not required. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get no_restart
my $no_restart = $svcrst_status->no_restart();
```

pending( )

Use this method to retrieve the number of pending service restart requests. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get pending
my $pending = $svcrst_status->pending();
```

pending_restart( )

Use this method to retrieve the number of required force restart requests that are still pending. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get pending_restart
my $pending_restart = $svcrst_status->pending_restart();
```

processing( )

Use this method to retrieve the number of pending restart requests that are not required and not forced. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get processing
my $processing = $svcrst_status->processing();
```

restarting( )

Use this method to retrieve the number of restarting services. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get restarting
my $restarting = $svcrst_status->restarting();
```

success( )

Use this method to retrieve the number of successful service restart requests. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get success
my $success = $svcrst_status->success();
```

timeouts( )

Use this method to retrieve the number of timeouts for service restart requests. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get timeouts
my $timeouts = $svcrst_status->timeouts();
```

Infoblox::Grid::SmartFolder::GroupBy - Smart Folder Group By object

---

DESCRIPTION

Defines grouping information in a global or personal smart folder.

CONSTRUCTOR

```
my $group_by = Infoblox::Grid::SmartFolder::GroupBy->new(
    value                => $string,            #Required
    enable_grouping      => "true" | "false",   #Required
    value_type           => "EXTATTR" | "NORMAL", #Optional / Default is "EXTATTR"
);
```

MODULE METHODS

The following functions can be applied to a GroupBy object.

Infoblox::Grid::GlobalSmartFolder->group_bys( )

Use this function to specify a list of "group by" items to store in a global smart folder.

Example

```
#Construct an object
my $group_by_state = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                    enable_grouping => 'true',
                                                    value => "State",
                                                    value_type => "EXTATTR",
                                                   );

my $group_by_vcluster = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                  enable_grouping => 'true',
                                                  value => "v_cluster",
                                                  value_type => "NORMAL",
                                                 );
# Configure group_by items
my $response = $GlobalSmartFolder->group_bys([$group_by_state,$group_by_vcluster]);
```

Infoblox::Grid::PersonalSmartFolder->group_bys( )

Use this function to specify a list of "group by" items to store in a personal smart folder.

Example

```
#Construct an object
my $group_by_state = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                    enable_grouping => 'true',
                                                    value => "State",
                                                    value_type => "EXTATTR",
                                                   );
```

```
my $group_by_vcluster = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                        enable_grouping => 'true',
                                                        value => "v_cluster",
                                                        value_type => "NORMAL",
                                                       );
# Configure group_by items
my $response = $PersonalSmartFolder->group_bys([$group_by_state,$group_by_vcluster]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a SmartFolder::GroupBy object.

value( )

Use this method to specify the name of the attribute (when value_type is "EXTATTR" or "NORMAL"). The possible values for the value attribute are v_datacenter, v_cluster, v_host, v_entity_type, port_vlan_name, network_component_name, network_component_port_name, and any valid extensible attribute in the appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are strings corresponding to extensible attributes, object types, or object names.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting value
my $value = $group_by->value();
# Modifying value
$group_by->value("Country");
```

value_type( )

Use this method to set or retrieve the value type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

"EXTATTR" and "NORMAL" are supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting value_type
my $value_type = $group_by->value_type();
# Modifying value_type
$group_by->value_type("EXTATTR");
```

enable_grouping( )

Use this method to set or retrieve the enable grouping attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_grouping flag or "false" to deactivate/unset it. "group by" rules where enable_grouping is set to "false" will be ignored when retrieving the corresponding smart folder.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting enable_grouping
my $enable_grouping = $group_by->enable_grouping();
# Modifying enable_grouping
$group_by->enable_grouping("true");
```

SAMPLE CODE

##Preparation prior to a smart folder group by object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a smart folder query item object

```
my $group_by_state = Infoblox::Grid::SmartFolder::GroupBy->new(
                                                        enable_grouping => 'true',
                                                        value => "State",
                                                        value_type => "EXTATTR",
                                                       );
unless ($group_by_state){
     die("Construct smart folder group_by item failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "SmartFolder::GroupBy object created successfully\n";
```

#Create a personal smart folder and use $group_by

```
 #create a personal smart folder and use $query_item
 my $smart_folder = Infoblox::Grid::PersonalSmartFolder->new(
    name         => "my_personal_folder",
    group_bys    => [$group_by_state],
  );

#put smart folder into session
$session->add($smart_folder)
  or die("Smart folder creation failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());

print "Smart folder creation successful\n";
```

#Clean up

```
my @result = $session->get(
    object => "Infoblox::Grid::PersonalSmartFolder",
    name   => "my_personal_folder"
);

unless (scalar(@result) == 0) {
    $session->remove($result[0]);
}

####PROGRAM ENDS####
```

NAME

Infoblox::Grid::SmartFolder::GroupByValue - Smart Folder Group By Value object

DESCRIPTION

Defines a group value as part of an Infoblox::Grid::SmartFolderChildren query.

CONSTRUCTOR

```
my $group_by_value = Infoblox::Grid::SmartFolder::GroupByValue->new(
    name                    => $string,             #Required
    value                   => $string,             #Required
);
```

MODULE METHODS

METHODS

This section describes all the methods that you can use to configure a SmartFolder::GroupByValue object.

name( )

Use this method to specify the extensible attribute, object type, or object name that is used to group objects.

Parameter

Valid values are strings corresponding to the names.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

value( )

Use this method to specify the value of the extensible attribute, object type, or object name.

Parameter

Valid values are strings corresponding to the required extensible or normal attribute values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

NAME

Infoblox::Grid::SmartFolder::QueryItem - Smart Folder Query Item object

---

DESCRIPTION

Manipulates a Smart Folder Query Item object that contains information about a query to be stored in a global or personal smart folder.

CONSTRUCTOR

```
 my $query_item = Infoblox::Grid::SmartFolder::QueryItem->new(
     name                   => $string,    #Required
     is_extensible_attribute => $string,    #Optional / Default is "true"
     operator               => "eq" | "ne" | "lt" | "gt" | "leq" | "geq" | "begins with" | "does not begin
with" | "ends with" | "does not end with" | "has value" | "does not have value" | "within" | "on" | "today"
| "yesterday" | "this week" | "this month",    #Required
     value                  => $string | $num | $boolean | type of extensible attribute definition,
#Optional / Default is undefined
 );
```

MODULE METHODS

The following functions can be applied to a query item object.

Infoblox::Grid::GlobalSmartFolder->query_items( )

Use this function to specify a list of query items to store in a global smart folder.

Example

```
#Construct an object
  my $query_item1 = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                   => "Building",
    is_extensible_attibute => "true",
    operator               => "eq",
    value                  => "office1"
);

#Construct an object
  my $query_item2 = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                   => "address",
    is_extensible_attibute => "false",
    operator               => "ne",
    value                  => "10.0.0.1"
);

# Configure query items
my $response = $GlobalSmartFolder->query_items([$query_item1,$query_item2]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a SmartFolder::QueryItem object.

is_extensible_attribute( )

Use this method to indicate whether this smart folder query item is an extensible or not. When the attribute is_extensible_attribute is "true", the query item is an extensible attribute. When it is "false", it is a normal attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "true" or "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting is_extensible_attribute
my $is_extensible_attribute = $query_item->is_extensible_attribute();
# Modifying is_extensible_attribute
$query_item->is_extensible_attribute("true");
```

name( )

Use this method to set or retrieve the name of the smart folder query item. The possible values for the name attribute are

```
address
circuit_id
comment
disabled
duid
is_leaf_network
last_discovered_timestamp
locked
mac_address
name
network_component_name
network_component_port_name
network_view
port_vlan_name
record_type
remote_id
server_association_type
service
service_status
type
unmanaged
v_cluster
v_datacenter
v_entity_type
v_host
was_conflict
zone_func
zone_type
```

or any valid extensible attribute definition name present in the system.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name for the smart folder query item.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting name
my $name = $query_item->name();
# Modifying name
$query_item->name("Region");
```

operator( )

Use this method to set or retrieve the operator used in the query.

Parameter

Valid values are any of the following strings: "eq", "ne", "lt", "gt", "geq", "leq", "begins with", "does not begin with", "ends with", "does not end with", "has value", "does not have value", "within", "on", "today", "yesterday", "this week", "this month" and "inheritance state equals".

"has_value" and "does not have value" apply to extensible attribute values only.

For valid values for 'value' parameter for the "within" operator, please see the description of the 'value' method.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting operator
my $operator = $query_item->operator();
# Modifying operator
$query_item->operator("today");
```

value( )

Use this method to set or retrieve the value used in the query.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired value in string format.

For the "within" operator, the following format is supported: n [d/w/m], where n is the number of days/weeks/months depending on the unit following it. The unit is required. For example, 4d (4 days), 1w (1 week), or 7m (7 months)

For the following query items, a boolean value 'true' or 'false' will be expected: "disabled", "is_leaf_network", "locked".

For a "type" query item, a valid value is one of:

```
'All'
'AllNetwork'
'AllTemplate'
'DhcpFailoverAssoc'
'DhcpFilter'
'DHCPObjects'
'DhcpRange'
'DhcpRangeTemplate'
'DNSObjects'
'FixedAddress'
'FixedAddressTemplate'
'Host'
'IPAMObjects'
'IPv4DHCPObjects'
'IPv6DhcpFilter'
'IPv6DHCPObjects'
'IPv6DhcpRange'
'IPv6DhcpRangeTemplate'
'IPv6FixedAddress'
'IPv6FixedAddressTemplate'
'IPv6Lease'
'IPv6Network'
'IPv6NetworkTemplate'
'IPv6OptionSpace'
'IPv6SharedNetwork'
'MacFilterAddress'
'Member'
'Network'
'NetworkTemplate'
'Network/Zone/Range/Member'
'NsGroup'
'OptionFilterMatchRule'
'OptionSpace'
'Reservation'
'ResourceRecord'
'RoamingHost'
'SharedNetwork'
'SharedRecordGroup'
'View'
'Zone'
```

For a "record_type" query item a valid value is one of:

```
'A'
'AAAA'
'All types'
'CNAME'
'DNAME'
'MX'
```

```
'PTR'
'SRV'
'TXT'
```

For a "service_status" query item a valid value is one of:

```
'FAILED'
'INACTIVE'
'OFFLINE'
'WARNING'
'WORKING'
```

For a "zone_func" query item a valid value is one of:

```
'Forward-mapping Zone'
'IPv4 Reverse-mapping Zone'
'IPv6 Reverse-mapping Zone'
```

For a "zone_type" query item a valid value is one of:

```
'Authoritative'
'Delegation'.
'Forward'
'Stub'
```

For a "v_type" query item a valid value is one of:

```
'HostSystem'
'VirtualCenter'
'VirtualMachine'
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting value
my $value = $query_item->value();
# Modifying value
$query_item->value("Santa Clara");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, modify. This sample also includes error handling for the operations.

##Preparation prior to a smart folder query item object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a smart folder query item object

```
my $query_item = Infoblox::Grid::SmartFolder::QueryItem->new(
    name                      => "Country",
    is_extensible_attribute   => "true",
    operator                  => "eq",
    value                     => "Canada",
);
unless ($query_item){
     die("Construct smart folder query item failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
```

```
print "SmartFolder::QueryItem object created successfully\n";
```

#Create a personal smart folder and use $query_item

```
#create a personal smart folder and use $query_item
my $smart_folder = Infoblox::Grid::PersonalSmartFolder->new(
   name         => "my_personal_folder",
   query_items  => [$query_item],
 );

#put smart folder into session
$session->add($smart_folder)
  or die("Smart folder creation failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());

print "Smart folder creation successful\n";
```

#Get and modify the query items

```
#get the personal smart folder object from session
my @result = $session->get(
    object => "Infoblox::Grid::PersonalSmartFolder",
    name   => "my_personal_folder"
);

unless (scalar(@result) == 0) {
    my $smart_folder = $result[0];

    if ($smart_folder) {

      #modify query_items
      $query_item->value("France");
      $smart_folder->query_items([$query_item]);

      #update session
      $session->modify($smart_folder)
        or die("modify smart_folder my_personal_folder failed: ",
            $session->status_code(), $session->status_detail());
          }
       } else {
         print "No smart folder found.";
       }
```

#Clean up

```
@result = $session->get(
    object => "Infoblox::Grid::PersonalSmartFolder",
    name   => "my_personal_folder"
);

unless (scalar(@result) == 0) {
    $session->remove($result[0]);
}

####PROGRAM ENDS####
```

NAME

Infoblox::Grid::SmartFolderChildren - Smart Folder retrieval item.

DESCRIPTION

This module helps read the objects that are associated with either a smart folder (global or personal) or a set of queries that users can make without saving a smart folder object on the appliance.

This interface can be used for both "filtering" and "grouping" the results of smart folder associated objects.

CONSTRUCTOR

The object cannot be constructed. It can only be returned as part of a search.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a personal smart folder object.

Infoblox::Session->search( )

Use this method to search for SmartFolderChildren objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
 Apply the following attributes to search for a specific SmartFolderChildren object:

  query_items                  - Required. A list of Infoblox::Grid::SmartFolder::QueryItem objects.
  smart_folder_name            - Required. PersonalSmartFolder/GlobalSmartFolder name in string
format.
  smart_folder_type            - Optional. "Global" / "Personal", "Global" if not specified.
  smart_folder_group_bys       - Optional. A list of Infoblox::Grid::SmartFolder::GroupBy objects.
  smart_folder_group_by_values - Optional. A list of Infoblox::Grid::SmartFolder::GroupByValue
objects.

 Both "smart_folder_name" and "query_items" are marked "Required" but they cannot be specified
together. Note the following guidelines:

 - "query_items" cannot be specified when "smart_folder_name" is specified because if
"smart_folder_name" is specified, all the properties of a query can be derived from that smart
folder.

 - "query_items" can be specified with "smart_folder_group_bys". In this case, the results are
grouped by specified group_bys attribute and a list of intermediate objects are returned.

 - When only "smart_folder_name" is specified, it runs like a query using all properties from this
folder and returning the results accordingly.

 - When "smart_folder_group_bys" is specified with "smart_folder_name", the query is used from the
specified smart folder; however, the results are shown from the level listed in
"smart_folder_group_bys".

 - "smart_folder_group_bys" by itself cannot be an argument since it does not provide sufficient
input.
```

```
 - "smart_folder_group_by_values" by itself cannot be an argument since it does not provide
sufficient input.

 - For the non-saved smart folder query, the "smart_folder_group_by_values" can be used to specify
the level of results to return. "smart_folder_group_bys" must also be specified in this case.
```

Example

```
  Please see the 'SAMPLE CODE' section below.
```

METHODS

This section describes all the methods that you can use to retrieve the attribute values of a SmartFolderChildren object.

is_matching_object( )

Use this method to retrieve the is_matching_object flag.

Parameter

The flag will be "true" if a matching object is returned inside the value(); if not, the attribute `value()` will contain the name of the intermediate object.

value( )

Use this method to retrieve the value of the object.

Parameter

This attribute will contain either an actual object matching the query (if is_matching_object is "true") or a string describing the name of the intermediate object.

Intermediate objects are the extensible attribute value objects for which the grouping was requested. Matching objects are the DB objects that matched the query specified.

value_type( )

Use this method to retrieve the type of the returned value.

Parameter

If is_matching_object is "false", this will contain one of: "STRING" / "INTEGER" / "DATE" / "BOOLEAN".

comment( )

Use this method to retrieve the comment.

Parameter

This attribute will return the value of the `comment()` attribute of the associated object, if `is_matching_object()` is "true". It will return undef if is_matching_object is "false".

extattrs( )

Use this method to retrieve the extensible attributes. This attribute is read-only and cannot be set.

Parameter

This attribute will return the value of the `extattrs()` attribute of the associated object (if `is_matching_object()` is "true"). It will return undef if is_matching_object is "true"). It will return undef if is_matching_object is "false".

extensible_attributes( )

Use this method to retrieve the extensible attributes.

Parameter

This attribute will return the value of the `extensible_attributes()` attribute of the associated object (if `is_matching_object()` is "true"). It will return undef if is_matching_object is "false".

SAMPLE CODE

```
USE-CASES & EXAMPLES:

#########################################################################
```

```
# Case 1 : Fetching objects based on the query defined for an existing folder
##############################################################################

my @retrieved_objs = $session->search(
            object =>"Infoblox::Grid::SmartFolderChildren" ,
            smart_folder_name => "global_smart_folder_1"
          );

my $object = $retrieved_objs[0];

if ($object->is_matching_object())
{
   print $object->comment();
   # $object->extensible_attributes() will contain the object's
   # extensible attributes
   #
   # This will be the actual matching object
   # $object->value();
}
else
{
   # Name of the intermediate group, use this to fetch another level if needed
   # This will be "USA", "Canada" etc
   # if the grouping was on "Country" for example
   print $object->value();
   print $object->value_type();
}

##############################################################################
# Case 2 : Fetching objects based on the smart folder and a given group_by values
##############################################################################

my $groupbyvalue1 = Infoblox::Grid::SmartFolder::GroupByValue->new(
          name => "Country",
          value => "USA",
);
my $groupbyvalue2 = Infoblox::Grid::SmartFolder::GroupByValue->new(
          name => "State",
          value => "CA",
);

my  @retrieved_objs = $session->search(
      object =>"Infoblox::Grid::SmartFolderChildren" ,
      smart_folder_name => "global_smart_folder_1",
      smart_folder_group_by_values => [$groupbyvalue1, $groupbyvalue2],
         );

my $object = $retrieved_objs[0];
if ($object->is_matching_object())
{
   print $object->comment();
   # $object->extensible_attributes() will contain the object's
   # extensible attributes
   #
   # This will be the actual matching object
   # $object->value();
}
else
{
   # Name of the intermediate group, use this to fetch another level if needed
   print $object->value();
   print $object->value_type();
}

##############################################################################
# Case 3 : Fetching objects based on the not-saved smart folder query, no grouping
##############################################################################

my  @retrieved_objs = $session->search(
      object =>"Infoblox::Grid::SmartFolderChildren" ,
      #This query will only return intermediate objects
      query_items => [queryitem1, queryitem2],
         );

my $object = $retrieved_objs[0];
if ($object->is_matching_object())
{
   print $object->comment();
   # $object->extensible_attributes() will contain the object's
   # extensible attributes
   #
   # This will be the actual matching object
```

```
    # $object->value();

}
else
{
    # This shall never happen
}

#########################################################################
# Case 4 : Fetching objects based on the not-saved smart folder query & with top level grouping
#########################################################################

my  @retrieved_objs = $session->search(
      object =>"Infoblox::Grid::SmartFolderChildren" ,
      query_items => [queryitem1, queryitem2],
      smart_folder_group_bys => [$groupby1, $groupby2],
         );

my $object = $retrieved_objs[0];

NAME

Infoblox::Grid::SNMP::Admin - Manages a SNMP Admin object.

DESCRIPTION

SNMP (Simple Network Management Protocol) is a protocol that administrators use to manage network devices and monitor their processes. An SNMP-managed appliance, such as an Infoblox appliance, has an SNMP agent that collects data and stores them as objects in MIBs (Management Information Bases). You can configure an Infoblox appliance as an SNMP-managed appliance. Infoblox appliances support SNMP versions 1, 2, and 3. You can enter values for sysContact, sysLocation, sysName, sysDescr managed objects in MIB-II, the standard MIB defined in RFC 1213. Once these values are set on the appliance, the administrators can send queries for these values from management systems that are allowed to send queries to the appliance.

CONSTRUCTOR

For SNMP Admin objects used as part of an HA pair

```
my $snmp = Infoblox::Grid::SNMP::Admin->new(
    sysContact_node1  => $string,      #Optional / Default is empty
    sysDescr_node1    => $string,      #Optional / Default is empty
    sysLocation_node1 => $string,  #Optional / Default is empty
    sysName_node1     => $string,  #Optional / Default is hostname of appliance
    sysContact_node2  => $string,      #Optional / Default is empty
    sysDescr_node2    => $string,      #Optional / Default is empty
    sysLocation_node2 => $string,  #Optional / Default is empty
    sysName_node2     => $string,  #Optional / Default is hostname of appliance
 );
```

otherwise

```
my $snmp = Infoblox::Grid::SNMP::Admin->new(
    sysContact  => $string,  #Optional / Default is empty
    sysDescr    => $string,  #Optional / Default is empty
    sysLocation => $string,  #Optional / Default is empty
    sysName     => $string,  #Optional / Default is hostname of appliance
 );
```

When the SNMP Admin object is not used as part of an HA pair, sysContact/sysContact_node1, sysDescr/sysDescr_node1, ... are equivalent. The _node2 fields will be empty.

MODULE METHODS

The following functions are available to apply to an SNMP admin object.

Infoblox::Grid->snmp_admin( )

Use this function to specify an SNMP admin at the grid level. See Infoblox::Grid->snmp_admin() for parameters and return values.

Example

```
#Construct an object
 my $snmp = Infoblox::Grid::SNMP::Admin->new(
   sysContact  => "Somebody",
   sysDescr    => "SunOS noc1 5.6 Generic_105181-03 sun4u",
   sysLocation => "Infoblox Headquarter",
   sysName     => "noc1"
);

#Configure snmp at grid level
my $response = $grid->snmp_admin($snmp);
```

Infoblox::Grid::Member->snmp_admin( )

Use this function to specify an SNMP admin at the member level. See Infoblox::Grid::Member->snmp_admin() for parameters and return values.

Example

```
#Construct an object
  my $snmp = Infoblox::Grid::SNMP::Admin->new(
    sysContact_node1  => "Somebody",
    sysDescr_node1    => "SunOS noc1 5.6 Generic_105181-03 sun4u",
    sysLocation_node1 => "Infoblox Headquarter",
    sysName_node1     => "noc1"
);

# Configure snmp at member level
$member->snmp_admin($snmp);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an SNMP admin object.

sysContact( )

Use this method to set or retrieve the name of the contact person for the Simple Network Management Protocol (SNMP) agent host.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the contact person in string format. The maximum length of the name is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysContact
my $sysContact = $snmp->sysContact();
#Modify sysContact
$snmp->sysContact("Infoblox");
```

sysContact_node1( )

Use this method to set or retrieve the name of the contact person for the Simple Network Management Protocol (SNMP) agent host on node 1 of an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the contact person in string format. The maximum length of the name is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysContact_node1
my $sysContact_node1 = $snmp->sysContact_node1();
#Modify sysContact_node1
$snmp->sysContact_node1("Infoblox");
```

sysContact_node2( )

Use this method to set or retrieve the name of the contact person for the Simple Network Management Protocol (SNMP) agent host on node 2 of an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the contact person in string format. The maximum length of the name is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysContact_node2
my $sysContact_node2 = $snmp->sysContact_node2();
#Modify sysContact_node2
$snmp->sysContact_node2("Infoblox");
```

sysDescr( )

Use this method to set or retrieve the name and version ID of the system's hardware type, the software Operational System (OS), and networking software that the appliance is running.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Useful information about the hardware and software described in string format. The maximum length of the sysDescr is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysDescr
my $sysDescr = $snmp->sysDescr();
#Modify sysDescr
$snmp->sysDescr("SunOS noc2 5.6 Generic_105181-03 sun5u");
```

sysDescr_node1( )

Use this method to set or retrieve the name and version ID of the system's hardware type, the software Operational System (OS), and networking software that the appliance is running on node 1 of an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Useful information about the hardware and software described in string format. The maximum length of the sysDescr_node1 is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysDescr_node1
my $sysDescr_node1 = $snmp->sysDescr_node1();
#Modify sysDescr_node1
$snmp->sysDescr_node1("SunOS noc2 5.6 Generic_105181-03 sun5u");
```

sysDescr_node2( )

Use this method to set or retrieve the name and version ID of the system's hardware type, the software Operational System (OS), and networking software that the appliance is running on node 2 of an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Useful information about the hardware and software described in string format. The maximum length of the sysDescr_node2 is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysDescr_node2
my $sysDescr_node2 = $snmp->sysDescr_node2();
#Modify sysDescr_node2
$snmp->sysDescr_node2("SunOS noc2 5.6 Generic_105181-03 sun5u");
```

sysLocation( )

Use this method to set or retrieve the physical location of the appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The physical location of the appliance in string format. The maximum length of the sysLocation is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysLocation
my $sysLocation = $snmp->sysLocation();
#Modify sysLocation
$snmp->sysLocation("Infoblox Headquarter5");
```

sysLocation_node1( )

Use this method to set or retrieve the physical location of the appliance on node 1 of an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The physical location of the appliance in string format. The maximum length of the sysLocation_node1 is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysLocation_node1
my $sysLocation_node1 = $snmp->sysLocation_node1();
#Modify sysLocation_node1
$snmp->sysLocation_node1("Infoblox Headquarter5");
```

sysLocation_node2( )

Use this method to set or retrieve the physical location of the appliance on node 2 of an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The physical location of the appliance in string format. The maximum length of the sysLocation_node2 is 50 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysLocation_node2
my $sysLocation_node2 = $snmp->sysLocation_node2();
#Modify sysLocation_node2
$snmp->sysLocation_node2("Infoblox Headquarter5");
```

sysName( )

Use this method to set or retrieve the fully qualified domain name (FQDN) of the appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The fully qualified domain name (FQDN) of the appliance in string format. The maximum length of the sysName is 50 characters. The default value of sysName is the hostname of the Infoblox appliance.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysName
my $sysName = $snmp->sysName();
#Modify sysName
$snmp->sysName("Infobloxnoc2");
```

sysName_node1( )

Use this method to set or retrieve the fully qualified domain name (FQDN) of the appliance on node 1 of an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The fully qualified domain name (FQDN) of the appliance in string format. The maximum length of the sysName_node1 is 50 characters. The default value of sysName_node1 is the hostname of the Infoblox appliance.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysName_node1
my $sysName_node1 = $snmp->sysName_node1();
#Modify sysName_node1
$snmp->sysName_node1("Infobloxnoc2");
```

sysName_node2( )

Use this method to set or retrieve the fully qualified domain name (FQDN) of the appliance on node 2 of an HA pair.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The fully qualified domain name (FQDN) of the appliance in string format. The maximum length of the sysName_node2 is 50 characters. The default value of sysName_node2 is the hostname of the Infoblox appliance.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get sysName_node2
my $sysName_node2 = $snmp->sysName_node2();
#Modify sysName_node2
$snmp->sysName_node2("Infobloxnoc2");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, modify and remove. This sample also includes error handling for the operations.

#Preparation prior to an SNMP admin object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Creating an SNMP admin object

```
my $snmp = Infoblox::Grid::SNMP::Admin->new(
    sysContact  => "Somebody",
    sysDescr    => "SunOS noc1 5.6 Generic_105181-03 sun4u",
    sysLocation => "Infoblox Headquarter",
    sysName     => "noc1"
    );
unless($snmp) {
     die("Construct a SNMP Admin failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "SNMP Admin object created successfully\n";
```

#Getting the grid object from the appliance through session

```
 my @result = $session->get(
    object => "Infoblox::Grid",
    name   => "Infoblox"
    );

my $grid = $result[0];
unless ($grid) {
       die("Get Grid object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get Grid object found at least 1 matching entry\n";

      #Modifying the value of the specified object.
        $grid->snmp_admin($snmp);  #Applying the changes.
        $session->modify($grid);
        print "SNMP Admin modified successfully\n";
```

#Modify SNMP admin attribute sysName

```
 #Modify existing attribute sysName
$snmp->sysName("noc2.infoblox.com");

 #Apply changes to the Grid object.
$grid->snmp_admin($snmp);

 #Update Grid object through the Infoblox session.
$session->modify($grid)
```

```
            or die("modify Grid object failed: ",
                $session->status_code() . ":" . $session->status_detail());
        print "Modified SNMP Admin sysName of Grid object successful\n";
```

#Remove SNMP admin attribute from Grid object

```
  #Apply changes to the Grid object to Un-def SNMP Admin object.
  $grid->snmp_admin(undef);

  #Update Grid object through the Infoblox session.
  $session->modify($grid)
            or die("Remove SNMP Admin from Grid object failed: ",
                $session->status_code() . ":" . $session->status_detail());
        print "Removed SNMP Admin from Grid object successful\n";

 ####PROGRAM ENDS####

NAME

Infoblox::Grid::SNMP::IPAMThreshold - IPAM Utilization SNMP Threshold object.

DESCRIPTION

The object provides information about the IPAM utilization SNMP threshold.

CONSTRUCTOR

```
my $obj = Infoblox::Grid::SNMP::IPAMThreshold->new(
    'reset_value'   => $uint,     # optional
    'trigger_value' => $uint,     # optional
);
```

METHODS

This section describes all the methods that can be used to retrieve the attribute values of an object.

reset_value( )

Use this method to set or retrieve a reset threshold value for the trap.

Returns

Valid value is unsigned integer between 0 and 100 inclusive.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value = $obj->reset_value();
#Set attribute value
$obj->reset_value(55);
```

trigger_value( )

Use this method to set or retrieve a trigger threshold value for the trap.

Returns

Valid value is unsigned integer between 0 and 100 inclusive.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value = $obj->trigger_value();
#Set attribute value
$obj->trigger_value(55);
```

NAME

Infoblox::Grid::SNMP::IPAMTrap - IPAM Utilization SNMP Trap object.

DESCRIPTION

The object provides information about the IPAM utilization SNMP trap.

CONSTRUCTOR

```
my $obj = Infoblox::Grid::SNMP::IPAMTrap->new(
    'enable_email_warnings' => 'true' | 'false',      # optional
    'enable_snmp_warnings'  => 'true' | 'false',      # optional
);
```

METHODS

This section describes all the methods that can be used to retrieve the attribute values of an object.

enable_email_warnings( )

Use this method to enable or disable email notifications.

Returns

Specify 'true' to enable email notifications or 'false' to disable it. The default value is 'true'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value = $obj->enable_email_warnings();
#Set attribute value
$obj->enable_email_warnings('true');
```

enable_snmp_warnings( )

Use this method to enable or disable SNMP notifications.

Returns

Specify 'true' to enable SNMP notifications or 'false' to disable it. The default value is 'true'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value = $obj->enable_snmp_warnings();
#Set attribute value
$obj->enable_snmp_warnings('true');
```

NAME

Infoblox::Grid::SNMP::QueriesUser - Grid SNMP QueriesUser object.

DESCRIPTION

The Grid SNMP Queriesuser object is used to set or retrieve the user name of an SNMPv3 user.

CONSTRUCTOR

```
my $query_user1 = Infoblox::Grid::SNMP::QueriesUser->new(
          user => $snmp_user1,
          comment => "query comment 1"
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an SNMPv3 QueriesUser object.

user()

Use this method to set or retrieve the user name of an SNMPv3 user.

Parameter

A reference to the Infoblox::Grid::SNMP::User object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get query user
my $query_user=$grid->snmpv3_query_users();
#Set query user
$grid->snmpv3_query_users([$query_user1,$query_user2];
```

NAME

Infoblox::Grid::SNMP::ThresholdTrap - Threshold Trap object.

DESCRIPTION

The Grid SNMP ThresholdTrap object is used to set the values of the thresholds of the SNMP traps.

CONSTRUCTOR

Use the following attributes to construct an Infoblox::Grid::SNMP::ThresholdTrap object.

```
my $threshold_trap = Infoblox::Grid::SNMP::ThresholdTrap->new(
    trap_type       =>   $string,      #Required
    trap_reset      =>   $uint,        #Optional
    trap_trigger    =>   $uint,        #Optional
);
```

MODULE METHODS

This section describes all the methods in the other modules that can be applied to a Threshold Trap object.

Infoblox::Grid->threshold_traps( )

Use this function to specify threshold traps at the grid level. See Infoblox::Grid->threshold_traps() for parameters and return values.

Example

```
#Get threshold traps
my $threshold_traps = $grid->threshold_traps();
#Modify threshold traps
my $threshold_traps = $grid->threshold_traps();
foreach(@$threshold_traps){if $_->trap_name() eq 'Rootfs'; $_->trap_reset=60;} #Change value for
'Rootfs' trap
$grid->threshold_traps($threshold_traps);
$session->modify($grid);
```

Infoblox::Grid::Member->threshold_traps( )

Use this function to specify threshold traps at the member level. See Infoblox::Grid::Member->threshold_traps() for parameters and return values.

Example

```
#Get threshold traps
my $threshold_traps = $member->threshold_traps();
#Modify threshold traps
my $threshold_traps = $member->threshold_traps();
foreach(@$threshold_traps){if $_->trap_name() eq 'Rootfs'; $_->trap_reset=60;} #Change value for
'Rootfs' trap
$grid->threshold_traps($threshold_traps);
$session->modify($member);
```

METHODS

This section describes all the methods that can be used to retrieve the attribute values of a Threshold Trap object.

trap_reset( )

Use this method to specify the threshold value to reset the trap.

Parameter

The trap_reset parameter is a positive integer. The default value depends on the trap_type.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the trap reset value
my $trap_reset = $threshold_trap->trap_reset();
#Set the trap reset value
$threshold_trap->trap_reset();
```

trap_trigger( )

Use this method to specify the threshold value to trigger the trap. The default value depends on the trap_type.

Parameter

The trap_trigger parameter is a positive integer. The default value depends on the trap_type.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the trap trigger
my $trap_trigger = $threshold_trap->trap_trigger();
#Set the trap trigger
$threshold_trap->trap_trigger();
```

trap_type( )

Use this method to get the type of a given trap.

Parameter

String that contains the trap type.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the trap type
my $trap_type = $threshold_trap->trap_type();
#Set the trap type
$threshold_trap->trap_type();
```

SAMPLE CODE

The following sample code demonstrates the session methods of a Threshold Trap object.

#Preparation prior to getting and modifying a grid member object

```
use strict;
use Infoblox;

my $session = Infoblox::Session->new(
```

```
            master   => "192.168.2.1",
            username => "admin",
            password => "infoblox"
  );

  unless ($session) {
     die("Session construction failed: ",
         Infoblox::status_code() . ":" . Infoblox::status_detail());
  }
  print "Session created successfully\n";
```

#Getting the grid level trap list from appliance through session

```
  #Getting the Grid object
  my @result = $session->get(
     object => "Infoblox::Grid",
     name   => "Infoblox"
     ); my $grid = $result[0];
  unless ($grid) {
        die("Get Grid object failed: ",
            $session->status_code() . ":" . $session->status_detail());
  }
  print "Get Grid object found at least 1 matching entry\n";

  #Extracting threshold traps
  my $ref_threshold_traps = $grid->threshold_traps();
  unless($ref_threshold_traps && ref($ref_threshold_traps) eq 'ARRAY' ){
      die("Get threshold traps list failed: ",
          $session->status_code() . ":" . $session->status_detail());
  }
  my @current_threshold_traps = @$ref_threshold_traps;
```

#Modify threshold traps list

```
  #Delete some traps from the list
  my @new_list = grep {$_->trap_type() ne "NetworkCapacity" && $_->trap_type() ne "Rootfs" }
@current_threshold_traps;
  #Create new "Rootfs" threshold trap
  my $new_rootfs_trap = Infoblox::Grid::SNMP::ThresholdTrap->new(
       trap_type => "Rootfs",
       trap_trigger => 95,
       trap_reset => 80,
   );
  unless($new_rootfs_trap){
      die("Creating new threshold trap failed: ",
          Infoblox::status_code() . ":" . Infoblox::status_detail());
  }
  push @new_list, $new_rootfs_trap;
  #Modify grid object
  unless($grid->threshold_traps(\@new_list)){
      die("Modifying threshold traps failed: ",
          Infoblox::status_code() . ":" . Infoblox::status_detail());
  }
  B<#Update Grid object through the Infoblox session.>
  $session->modify($grid)
             or die("modify Grid object failed: ",
                 $session->status_code() . ":" . $session->status_detail());
        print "Modified threshold traps of Grid object successful\n";
```

#Restore the old threshold traps

```
  #Apply changes to the Grid object to Un-def SNMP Admin object.
  $grid->threshold_traps(\@current_threshold_traps);  #Update Grid object through the Infoblox session.
  $session->modify($grid)
             or die("Restore threshold traps for Grid object failed: ",
                 $session->status_code() . ":" . $session->status_detail());

        print "Restored Grid object successful\n";

        ####PROGRAM ENDS####
```

NAME

Infoblox::Grid::SNMP::TrapNotification - Trap Notification object.

DESCRIPTION

This object represents the trap notification settings of the Infoblox::Grid and Infoblox::Grid::Member object. The object allows you to control which trap categories are enabled, and for which trap categories mail notification will be sent.

CONSTRUCTOR

Use the following parameters to construct the Infoblox::Grid::SNMP::TrapNotification object

```
my $trap_notification = Infoblox::Grid::SNMP::TrapNotification->new(
   trap_type       =>  $string,              #Required
   enable_email    =>  "true" | "false",     #Optional / Default is  "false"
   enable_trap     =>  "true" | "false",     #Optional / Default is  "true"
);
```

MODULE METHODS

The following functions are available to apply to an SNMP Trap Notification object.

Infoblox::Grid->trap_notifications( )

Use this function to specify trap notification settings at the grid level. See Infoblox::Grid->trap_notifications() for parameters and return values.

Example

```
#Get a reference to a trap notifications array
my $trap_notifications = $grid->trap_notifications();
#Modify trap notifications
my $notifications = $grid->trap_notifications();
foreach(@$notifications){if $_->trap_type() eq 'CPU'; $_->enable_email="true";} #Change value for
'CPU' trap
$grid->trap_notifications($notifications);
$session->modify($grid);
```

Infoblox::Grid::Member->trap_notifications( )

Use this function to specify a trap notifications at the member level. See Infoblox::Grid::Member->trap_notifications() for parameters and return values.

Example

```
#Get a reference to a trap notifications array
my $trap_notifications = $member->trap_notifications();
#Modify trap notifications
my $notifications = $member->trap_notifications();
foreach(@$notifications){if $_->trap_type() eq 'CPU'; $_->enable_email="true";} #Change value for
'CPU' trap
$member->trap_notifications($notifications);
$session->modify($member);
```

METHODS

This section describes all the methods that can be used to retrieve the attribute values of a Trap Notification object.

enable_email( )

Use this method to retrieve the enable_email flag of a Trap Notification object.

Parameter

none

Returns

The method returns the enable_email flag value.

Example

```
#Get  enable_email flag
my $enable_email = $trap_notification->enable_email();
#Set  enable_email flag
$trap_notification->enable_email();
```

enable_trap( )

Use this method to retrieve the enable_trap flag of a Trap Notification object.

Parameter

none

Returns

The method returns the enable_trap flag attribute value.

Example

```
#Get  enable_trap flag
my $enable_trap = $trap_notification->enable_trap();
#Set  enable_trap flag
$trap_notification->enable_trap();
```

trap_type( )

Use this method to retrieve the category of a trap in the Trap Notification object.

Parameter

none

Returns

The method returns the category of the trap attribute value.

Example

```
#Get category of trap
my $trap_type = $trap_notification->trap_type();
#Set category of trap
$trap_notification->trap_type();
```

NAME

Infoblox::Grid::SNMP::TrapReceiver - Grid SNMP TrapReceiver object.

DESCRIPTION

The Grid SNMP TrapReceiver object is used to set or retrieve the IP address and user name of a trap receiver.

CONSTRUCTOR

```
my $Infoblox::Grid::SNMP::TrapReceiver->new(
    address => $ip_address,   #Required
    user => $snmpv3user       #Required
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an SNMPv3 TrapReceiver object.

address()

Use this method to set or retrieve the IP address of the trap receiver.

Parameter

IPv4 address of the trap receiver

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get trap receiver address
my $ip=$trap_receiver->address();
#Set trap receiver address
$trap_receiver->address("192.168.1.2");
```

user()

Use this method to set or retrieve the user name for the trap receiver.

Parameter

A reference to the Infoblox::Grid::SNMP::User object or the user name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get trap receiver user
my $user=$trap_receiver->user();
#Set trap receiver user
$trap_receiver->user($user);
```

NAME

Infoblox::Grid::SNMP::User - Grid SNMP User object

DESCRIPTION

The Grid SNMP User object is used to set, get, search, modify, or remove an SNMPv3 user. An SNMPv3 user is a managment system that sends queries and receives traps from the appliance.

CONSTRUCTOR

```
#Constructor for a Grid SNMP User object
my $snmp_user = Infoblox::Grid::SNMP::User->new(
        name                => $string,                 #Required
        auth_protocol       => "none"| "md5" | "sha",   #Required
        privacy_protocol    => "none"| "des" | "aes",   #Required
        auth_password       => $string,                 #Optional. Required for MD5/SHA authentication
        comment             => $string,                 #Optional / Default is undefined
        disable             => "true" | "false",        #Optional / Default is "false"
        privacy_password    => $string,                 #Optional. Required for MD5/SHA authentication
        extattrs            => { $string => $extattr, ... },      #Optional / Default is undefined
 );
```

SESSION METHODS

This section describes all the methods in Infoblox::Session that you can apply to a Grid SNMP User object.

Infoblox::Session->get( )

Use this method to retrieve existing objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attributes to get a Grid SNMP User object:

name     -  user name in string format
comment  -  comment string
extattrs - Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->get(
        object      => "Infoblox::Grid::SNMP::User",
        name        => "testuser" );
```

Infoblox::Session->modify( )

Use this method to modify objects in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment
$snmp_user->comment("This is a modified comment");
# Submit modification
my $response = $session->modify( $snmp_user );
```

Infoblox::Session->search( )

Use this method to search for Grid SNMP User objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a Grid SNMP User object:

 name -  user name (regular expression)
 comment - comment string (regular expression)
 extattrs - Optional. A hash reference containing extensible attributes.
```

Example

```
# Search for all Grid SNMP User objects that start with "test"
my @retrieved_objs = $session->search(
    object      => "Infoblox::Grid::SNMP::User",
    name        => "test.*",
);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the object, and then submit it for removal.

Example

```
# Get Grid SNMP User objects with the same starting name
my @retrieved_objs = $session->get(
    object      => "Infoblox::Grid::SNMP::User",
    name        => "testuser" );
# find the desired object from the retrieved list.
my $desired_user = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_user );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an SNMPv3 user.

auth_password( )

Use this method to provide an authentication password for the user. This is a write-only attribute.

Parameter

Authentication password of the user in string format.

Returns

If a parameter is specified, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set the password
$snmp_user->auth_password("mysecret");
```

auth_protocol( )

Use this method to specify the authentication protocol of the user.

Parameter

Possible values for the authentication protocol are:

```
none
```

```
md5
sha
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get auth_protocol
my $proto = $snmp_user->auth_protocol();
#Set the protocol
$snmp_user->auth_protocol("md5");
```

comment( )

Use this method to provide a comment for the SNMPv3 User object.

Parameter

Comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $snmp_user->comment();
#Set the comment
$snmp_user->comment("This is a sample comment");
```

disable( )

Use this method to configure or retrieve the "disable" flag.

The default value is false; that is, the user is enabled.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable flag
my $disabled = $snmp_user->disable();
#Set the disable flag
$snmp_user->disable("true");
```

engine_id( )

Use this method to retrieve the SNMP engine ID.

This field is read-only.

Parameter

None

Returns

When called without parameters, the method returns the attribute value. Calling this method with a parameter results in an error.

Example

```
#Get engine_id
my $engine_id = $snmp_user->engine_id();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a SNMP user object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $snmp_user->extattrs();
#Modify extattrs
$snmp_user->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

name( )

Use this method to set or retrieve the name of an SNMPv3 user.

Parameter

Text with the name of the user.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $snmp_user->name();
#Modify name
$snmp_user->name("test_user");
```

privacy_password( )

Use this method to provide a password for the privacy protocol. This is a write-only attribute.

Parameter

Password in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set the password
$snmp_user->privacy_password("mysecret");
```

privacy_protocol( )

Use this method to specify encryption protocol for the SNMP packets.

Parameter

Possible values for the encryption protocol are:

```
none
des
aes
```

The values are case insensitive.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get privacy_protocol
my $proto = $snmp_user->privacy_protocol();
#Set the protocol
$snmp_user->privacy_protocol("aes");
```

    port           => $uint,                 # Optional
    protocol       => 'SCP' | 'FTP',         # Optional
    username       => $string,               # Optional
);
```

MODULE METHODS

The following functions are available to be applied to a syslog backup server object.

Infoblox::Grid->syslog_backup_servers( )

Use this method to set or retrieve an array that contains Grid-level syslog backup server settings. See Infoblox::Grid->syslog_backup_servers() for parameters and return values.

Example

```
#get syslog_backup_servers value
my $servers = $grid->syslog_backup_servers();

#modify syslog_backup_servers value
$grid->syslog_backup_servers([$server1, $server2]);
```

Infoblox::Grid::Member->syslog_backup_servers( )

Use this method to set or retrieve an array that contains syslog backup server settings for a Grid member. See Infoblox::Grid::Member->syslog_backup_servers() for parameters and return values.

Example

```
#get syslog_backup_servers value
my $servers = $grid_member->syslog_backup_servers();

#modify syslog_backup_servers value
$grid_member->syslog_backup_servers([$server1, $server2]);
```

METHODS

address( )

Use this method to set or retrieve the IPv4 or IPv6 address of a syslog backup server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), with each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get address value
my $address = $server->address();

#modify address value
$server->address('192.168.1.5');
```

directory_path( )

Use this method to set or retrieve the path for rotated syslog file replication.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired path in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get directory_path value
my $directory_path = $server->directory_path();

#modify directory_path value
$server->directory_path('/path/to/directory');
```

enable( )

Use this method to enable or disable the syslog backup server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable syslog backup server or 'false' to disable it. The default value is 'true'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get enable value
my $enable = $server->enable();

#modify enable value
```

```
$server->enable('true');
```

password( )

Use this method to set the syslog backup server password. This is a write-only attribute.

Include the specified parameter to set the attribute value.

Parameter

The valid value is a desired password in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#modify password value
$server->password('infoblox');
```

port( )

Use this method to set or retrieve the transport layer port for connection to the syslog backup server.

Include the specified parameter to set the attribute value.

Parameter

The valid value is an unsigned integer between 0 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get port value
my $port = $server->port();

#modify port value
$server->port(22);
```

protocol( )

Use this method to set or retireve the transport layer protocol for the syslog backup server connection.

Include the specified parameter to set the attribute value.

Parameter

The valid values are 'FTP' and 'SCP'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get protocol value
my $protocol = $server->protocol();

#modify protocol value
$server->protocol('SCP');
```

username( )

Use this method to set or retrieve the username for the syslog backup server.

Include the specified parameter to set the attribute value.

Parameter

Valid value is a desired username in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get username value
my $username = $server->username();

#modify username value
$server->username('admin');
```

NAME

Infoblox::Grid::SyslogServer - Syslog server object.

DESCRIPTION

Syslog is a widely used mechanism for logging system events. Infoblox appliances generate syslog messages which can be viewed through the system log viewer and downloaded to a directory on your management station. In addition, the Infoblox appliance can be configured to send the messages to one or more external syslog servers for later analysis. Syslog messages provide information about appliance operations and processes. Also, the appliance can include audit log messages and specific BIND messages among the messages sent to the syslog server.

CONSTRUCTOR

```
 my $syslog_server = Infoblox::Grid::SyslogServer->new(
        address             => $address,                          #Required
        connection_type     => "tcp" | "udp" | "stcp",            #Optional / Default is "udp"
        local_interface     => "any" | "mgmt" | "lan",            #Optional / Default is "any"
        message_source      => "any" | "internal" | "external",   #Optional / Default is "any"
        port                => $num,                              #Optional / Default is 514 for TCP/UDP,
6514 for STCP
        severity            => "debug" | "info" | "notice" | "warning" | "err" | "crit" | "alert" | "emerg",
#Optional / Default is "debug"
        certificate         => $fname,  #Optional / Default is undefined

 );
```

MODULE METHODS

The following functions are available to be applied to a syslog server object.

Infoblox::Grid->syslog_server( )

Use this function to specify a syslog server at the grid level on the Infoblox appliance. See Infoblox::Grid->syslog_server() for parameters and return values.

Example

```
       #Construct a syslog server object
       my $syslog_server1 = Infoblox::Grid::SyslogServer->new(
                               address => "1.1.1.1",
                             );

       #Configure syslog server on the Infoblox grid object
       my $responce = $grid->syslog_server([$syslog_server1]);
```

Infoblox::Grid::Member->syslog_server( )

Use this function to specify a syslog server at the member level on the Infoblox appliance. See Infoblox::Grid::Member->syslog_server() for parameters and return values.

Example

```
#Construct a syslog server object
my $syslog_server2 = Infoblox::Grid::SyslogServer->new(
                       address => "2.2.2.2",
                       severity => "debug",
                     );

#Configure syslog server on the grid member object
my $responce = $grid_member->syslog_server([$syslog_server2]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute value of a syslog server object.

address( )

Use this method to set or retrieve the IPv4 or IPv6 address of a syslog server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), with each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get address
my $address = $syslog_server->address();
#Modify address
$syslog_server->address("3.3.3.3");
```

category_list( )

Use this method to set or retrieve the list of syslog categories for forwarding.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a list containing these values: 'NON_CATEGORIZED', 'ATP', 'DNS_CLIENT', 'DNS_CONFIG', 'DNS_DATABASE', 'DNS_DNSSEC', 'DNS_GENERAL', 'DNS_LAME_SERVERS', 'DNS_NETWORK', 'DNS_NOTIFY', 'DNS_QUERIES', 'DNS_QUERY_REWRITE', 'DNS_RESOLVER', 'DNS_RESPONSES', 'DNS_RPZ', 'DNS_SECURITY', 'DNS_UPDATE', 'DNS_UPDATE_SECURITY', 'DNS_XFER_IN', 'DNS_XFER_OUT', 'DNS_UNBOUND', 'DTC_HEALTHD', 'DTC_IDNSD', 'DHCPD', 'NTP', 'FTPD', 'TFTPD', 'CLOUD_API', 'MS_DNS_SERVER', 'MS_CONNECT_STATUS', 'MS_DNS_ZONE', 'MS_DHCP_SERVER', 'MS_DHCP_LEASE', 'MS_DHCP_CLEAR_LEASE', 'MS_SITES', 'MS_AD_USERS', 'AUTH_COMMON', 'AUTH_NON_SYSTEM', 'AUTH_UI_API', 'AUTH_ACTIVE_DIRECTORY', 'AUTH_RADIUS', 'AUTH_TACACS', 'AUTH_LDAP', 'OUTBOUND_API'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get category_list
my $category_list = $syslog_server->category_list();

#Modify category_list
$syslog_server->category_list(['DNS_CLIENT']);
```

certificate( )

Use this method to set a path to the file that contains a client certificate. This is a write-only attribute.

Note that the certificate must be set in order to establish an STCP connection.

Parameter

The valid value is a string that contains the path to the client certificate file.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify certificate
$syslog_server->certificate('/path/to/certificate.pem');
```

connection_type( )

Use this method to set or retrieve the connection type to the external syslog server. This method specifies whether the appliance uses TCP or UDP to connect to the external syslog server.

Note that the certificate must be set in order to establish an STCP connection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are: `"tcp", "udp", "stcp"`. The default value is "udp".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get connection_type
my $connection_type = $syslog_server->connection_type();
#Modify connection_type
$syslog_server->connection_type("tcp");
```

local_interface( )

Use this method to set or retrieve the interface through which the appliance sends syslog messages to the syslog server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are: `"any", "mgmt", "lan"`. The default value is "any".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get local_interface
my $local_interface = $syslog_server->local_interface();
#Modify local_interface
$syslog_server->local_interface("lan");
```

message_source( )

Use this method to set or retrieve the message source value of the syslog server. This method specifies which syslog messages the appliance sends to the external syslog server:

```
 Any     : The appliance sends both internal and external syslog messages.
 Internal: The appliance sends syslog messages that it generates.
 External: The appliance sends syslog messages that it receives from other appliances, such as syslog
servers and routers.
```

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are: "any", "internal", "external". The default value is "any".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get message_source
my $message_source = $syslog_server->message_source();
#Modify message_source
$syslog_server->message_source("internal");
```

only_category_list( )

Use this method to enable or disable forwarding of syslog messages that belong to the list of categories.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable forwarding or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get only_category_list
my $only_category_list = $syslog_server->only_category_list();

#Modify only_category_list
$syslog_server->only_category_list("true");
```

port( )

Use this method to set or retrieve the destination port number.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are between 1 and 65535. The default value is 514.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get port
my $port = $syslog_server->port();
#Modify port
$syslog_server->port("515");
```

severity( )

Use this method to set or retrieve the severity level for the syslog server. When you set a severity level, grid members send messages for that severity level plus all messages for all severity levels above it. The lowest severity level is "debug", and the highest severity level is "emerg".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are: "debug", "info", "notice", "warning", "err", "crit", "alert", "emerg". The default value is "debug".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get severity
my $severity = $syslog_server->severity();
#Modify severity
$syslog_server->severity("info");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a syslog server object such as add, modify, and remove. Also, this sample code includes error handling for the operations.

#Preparation prior to a syslog server object insertion

```
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",   #appliance host ip
    username => "admin",         #appliance user login
    password => "infoblox"       #appliance password
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully.\n";
```

#Create a syslog server object

```
my $syslog_server = Infoblox::Grid::SyslogServer->new(
                    address => "1.1.1.1",
                    severity => "debug"
                   );

unless($syslog_server) {
       die("Construct syslog server object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "syslog server object created successfully\n";
```

#Get Infoblox grid object and add syslog server to it

```
#Get Infoblox grid object
my @grid_objs = $session->get(
           object => "Infoblox::Grid",
           name   => "Infoblox"
       );

my $grid = $grid_objs[0];
unless ($grid) {
       die("Get Grid object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get Grid object found at least 1 matching entry\n";

#Apply the changes to the Grid object
$grid->syslog_server([$syslog_server]);

#Apply the changes
$session->modify($grid)
    or die("Modify Grid object failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "Grid object with syslog server updated to Infoblox appliance successfully\n";
```

#Modify syslog server object

```
#Get Infoblox grid object
my @grid_objs = $session->get(
           object => "Infoblox::Grid",
```

```
            name   => "Infoblox"
        );

 unless(scalar(@grid_objs) == 0){
        my $grid = $grid_objs[0];
        if($grid){
                my $syslog_obj = $grid->syslog_server();
                my @sys_servers = @{$syslog_obj};
                my $sys_server = $sys_servers[0];

                #Modifying the address of the syslog server object.
                $sys_server->address("2.2.2.2");

                #Modifying the connection_type of the syslog server object.
                $sys_server->connection_type("tcp");

                #Modifying the local_interface of the syslog server object.
                $sys_server->local_interface("lan");

                #Modifying the message_source of the syslog server object.
                $sys_server->message_source("external");

                #Modifying the port of the syslog server object.
                $sys_server->port("516");

                #Modifying the severity of the syslog server object.
                $sys_server->severity("warning");

                #Apply changes to the Grid object.
                $grid->syslog_server([$sys_server]);

                #Update Grid object through the Infoblox session.
                $session->modify($grid)
                             or die("modify Grid object failed: ",
                                 $session->status_code() . ":" . $session->status_detail());

                print "Grid object with modified syslog server updated to Infoblox appliance
successfully\n";
                        }
                 }
```

#Remove syslog server

```
 #Get Infoblox grid object
 my @grid_objs = $session->get(
            object => "Infoblox::Grid",
            name   => "Infoblox"
        );

 my $grid = $grid_objs[0];
 unless ($grid) {
        die("Get Grid object failed: ",
             $session->status_code() . ":" . $session->status_detail());
 }
 print "Get Grid object found at least 1 matching entry\n";

 #Remove syslog servers from the Grid object.
 $grid->syslog_server(undef);

 #Update Grid object through the Infoblox session.
 $session->modify($grid)
             or die("Remove syslog server from Grid object failed: ",
                 $session->status_code() . ":" . $session->status_detail());

 print "Removed syslog server from Grid object successfully\n";

NAME

Infoblox::Grid::TestResult - A result object returned by various test functions.

DESCRIPTION

The result object represents the evaluation status for various test operations (eg Threat Analytics server connectivity, Threat Protection server connectivity).

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to retrieve the attribute values of a test result object.

error_message( )

Use this method to retrieve the single error messages returned by the test operation. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value, that is an error message in string format.

Example

```
#Get error_message value
my $error_message = $object->error_message();
```

error_messages( )

Use this method to retrieve the list of error messages returned by the test operation. This is a read-only attribute.

Parameter

None

Returns

The method returns an array reference that contains error messages in a string format.

Example

```
#Get error_messages value
my $error_messages = $object->error_messages();
```

overall_status( )

Use this method to retrieve the overall status returned by the test operation. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get overall_status value
my $overall_status = $object->overall_status();
```

NAME

Infoblox::Grid::ThreatAnalytics - Grid Threat Analytics object.

DESCRIPTION

The object provides information about Grid Threat Analytics settings.

SESSION METHODS

The following functions can be applied to a Infoblox::Grid::ThreatAnalytics object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid Threat Analytics object
 object - Required. It must be set to "Infoblox::Grid::ThreatAnalytics".
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatAnalytics',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify some of the attributes of the retrieved_objs object.
$retrieved_objs->dns_tunnel_black_list_rpz_zones([$rpz]);
# Submit modification
my $response = $session->modify($retrieved_objs);
```

METHODS

This section describes all the methods that you can use to configure and retrieve values of the Grid Threat Analytics object.

current_moduleset( )

Use this method to set or retrieve the current threat analytics model set

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ThreatAnalytics::ModuleSet object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $current_moduleset = $obj->current_moduleset();
#Modify attribute value
$obj->current_moduleset($current_moduleset);
```

dns_tunnel_black_list_rpz_zones( )

Use this method to set or retrieve the list of Response Policy Zones for DNS tunnelling requests.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DNS::Zone objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $rpz_zones = $obj->dns_tunnel_black_list_rpz_zones();
#Modify attribute value
$obj->dns_tunnel_black_list_rpz_zones([$rpz_zone]);
```

download_threat_analytics_moduleset_update( )

Use this method to download and install the latest threar analytics module set update, available from the Infoblox threat analytics download server.

Key Reference

None

Returns

The method returns 1 when the operation succeeds, and 0 when the operation fails.

Example

```
my $res = $obj->download_threat_analytics_moduleset_update();
```

enable_auto_download( )

Use this method to set or retrieve the flag that indicates whether the automatic threat analytics module set download is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the automatic download of the threat analytics module set or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_auto_download value
my $enable_auto_download = $obj->enable_auto_download();
#Modify enable_auto_download value
$obj->enable_auto_download('false');
```

enable_scheduled_download( )

Use this method to set or retrieve the flag that indicates whether the scheduled download of the threat analytics module set is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the scheduled download of the threat analytics module set or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_scheduled_download value
my $enable_scheduled_download = $obj->enable_scheduled_download();
#Modify enable_scheduled_download value
$obj->enable_scheduled_download('false');
```

last_checked_for_update( )

Use this method to retrieve the last checked for update time for the analytics module set.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_checked_for_update value
my $last_checked_for_update = $obj->last_checked_for_update();
```

last_module_update_time( )

Use this method to retrieve the last update time for the threat analytics module set.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_module_update_time value
my $last_module_update_time = $obj->last_module_update_time();
```

last_module_update_version( )

Use this method to retrieve the version number of the last updated threat analytics module set.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_module_update_version value
my $last_module_update_version = $obj->last_module_update_version();
```

last_whitelist_update_time( )

Use this method to retrieve the last update time for the threat analytics whitelist.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_whitelist_update_time value
my $last_whitelist_update_time = $obj->last_whitelist_update_time();
```

last_whitelist_update_version( )

Use this method to retrieve the version number of the last updated threat analytics whitelist.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_whitelist_update_version value
my $last_whitelist_update_version = $obj->last_whitelist_update_version();
```

module_update_policy( )

Use this method to set or retrieve the updated policy for the threat analytics module set.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'AUTOMATIC' and 'MANUAL'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get module_update_policy value
my $module_update_policy = $obj->module_update_policy();
#Modify module_update_policy value
$obj->module_update_policy('MANUAL');
```

scheduled_download( )

Use this method to set or retrieve the schedule settings for the threat analytics module set download.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::Grid::ScheduleSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get scheduled_download value
my $scheduled_download = $obj->scheduled_download();
#Modify scheduled_download value
$obj->scheduled_download($sched_download);
```

test_threat_analytics_server_connectivity( )

Use this method ot test the connectivity with the Infoblox threat analytics download server.

Key Reference

None

Returns

The method returns an Infoblox::Grid::TestResult object if connectivity test occurs and 0 otherwise.

Example

```
my $res = $obj->test_threat_analytics_server_connectivity();
```

update_threat_analytics_moduleset( )

Use this method to update the threat analytics module set

Note that to update the threat analytics module set, the threat analytics update file should be uploaded via Infoblox::Session->import_data() method

Key Reference

```
mode - Optional. Specify 'TEST' to check uploaded module set or 'EXECUTE' to apply updates to the
current module set. The default value is 'EXECUTE'.
```

Returns

The method returns 1 when the operation succeeds, and 0 when the operation fails.

Example

```
my $res = $obj->update_threat_analytics_moduleset(mode => 'TEST');
```

NAME

Infoblox::Grid::ThreatAnalytics::Member - Member Analytics object.

DESCRIPTION

This object provides information about the member Threat Analytics settings.

SESSION METHODS

The following functions can be applied to a Infoblox::Grid::ThreatAnalytics::Member object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Member Threat Analytics object.

   comment  - The Threat Analytics member comment.
   ipv4addr - The Threat Analytics member IPv4 address.
   ipv6addr - The Threat Analytics member IPv6 address.
   name     - The Threat Analytics member name.
   status   - The Threat Analytics member status.
```

Example

```
my @retrieved_objs = $session->get(
    'object'      => 'Infoblox::Grid::ThreatAnalytics::Member',
    'name'        => 'host.com',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify attributes of an member object.
$member->enable_service('true');

# Submit modification
my $response = $session->modify($member);
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a Member Threat Analytics objects.

   comment  - The Threat Analytics member comment.
   ipv4addr - The Threat Analytics member IPv4 address.
   ipv6addr - The Threat Analytics member IPv6 address.
   name     - The Threat Analytics member name.
   status   - The Threat Analytics member status.
```

Example

```
my @retrieved_objs = $session->search(
    'object'      => 'Infoblox::Grid::ThreatAnalytics::Member',
    'name'        => 'host.*',
);
```

METHODS

This object provides information about the member Threat Analytics settings.

comment( )

Use this method to retrieve the descriptive comment for the Threat Analytics member object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get comment value
my $comment = $analytics_member->comment();
```

enable_service( )

Use this method to set or retrieve the flag which indicates whether the Threat Analytics engine is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable Threat Analytics engine and 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_service value
my $enable_service = $analytics_member->enable_service();
#Modify enable_service value
$analytics_member->enable_service('true');
```

ipv4addr( )

Use this method to retrieve the IPv4 address of the Threat Analytics member object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get ipv4addr value
```

```
my $ipv4addr = $analytics_member->ipv4addr();
```

ipv6addr( )

Use this method to retrieve the IPv6 address of the Threat Analytics member object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get ipv6addr value
my $ipv6addr = $analytics_member->ipv6addr();
```

move_black_list_rpz_cnames_to_threat_analytics_whitelist( )

Use this method to replace DNS RPZ CNAME records with appropriate Threat Analytics Whitelist objects.

Parameter

The valid value is an array reference that contains Infoblox::DNS::RPZRecord::CNAME objects.

Returns

The method returns true when the operation succeeds, and returns false when the operation fails.

Example

```
#move cnames to analytics whitelist
$analytics_member->move_black_list_rpz_cnames_to_threat_analytics_whitelist(@cnames);
```

name( )

Use this method to retrieve the name of the Threat Analytics member object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get name value
my $name = $analytics_member->name();
```

status( )

Use this method to retrieve the status of the Threat Analytics member object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'FAILED', 'INACTIVE', 'UNKNOWN', 'WARNING' and 'WORKING'.

Example

```
#Get status value
my $status = $analytics_member->status();
```

NAME

Infoblox::Grid::ThreatAnalytics::ModuleSet - A Grid Threat Analytics moduleset object.

DESCRIPTION

The Grid Threat Analytics moduleset represents an uploaded Apache Spark Module.

SESSION METHODS

The following functions can be applied to a Threat Analytics moduleset object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Threat Analytics moduleset object.

 version - Optional. The Threat Analytics moduleset version.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatAnalytics::ModuleSet',
    'version' => '1.0',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Threat Analytics moduleset object.

 version - Optional. The Threat Analytics moduleset version.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatAnalytics::ModuleSet',
    'version' => '1.*',
);
```

METHODS

version( )

Use this method to retrieve the Threat Analytics moduleset version.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get version
my $version = $object->version();
```

NAME

Infoblox::Grid::ThreatAnalytics::WhiteList - a Grid Threat Analytics White List object

---

DESCRIPTION

The Grid Threat Analytics White List provides information about allowed FQDNs in the DNS tunneling detection feature.

CONSTRUCTOR

```
my $whitelist = Infoblox::Grid::ThreatAnalytics::WhiteList->new(
   fqdn    => $fqdn,            # Required
   comment => $string,          # Optional / Default is undefined
   disable => 'true' | 'false', # Optional / Default is 'false'
);
```

SESSION METHODS

The following functions can be applied to a Infoblox::Grid::ThreatAnalytics::WhiteList object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $whitelist = Infoblox::Grid::ThreatAnalytics::WhiteList->new(
   fqdn => 'test.com',
   comment => 'test comment',
   disable => 'true',
);

#Submit for addition
my $response = $session->add( $whitelist );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Infoblox::Grid::ThreatAnalytics::WhiteList object.
 fqdn    - Optional. The Grid Threat Analytics White List FQDN.
 status  - Optional. The Grid Threat Analytics White List status.
 comment - Optional. The Grid Threat Analytics White List comment.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatAnalytics::WhiteList',
    'fqdn'   => 'test.com',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# modify whitelist object
$whitelist->comment('comment change');

# Submit modification
my $response = $session->modify( $whitelist );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Note that 'SYSTEM' Grid Threat Analytics White Lists cannot be removed.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::ThreatAnalytics::WhiteList',
    fqdn   => 'test.com');

#Find the desired object from the retrieved list.
my $desired_whitelist = $retrieved_objs[0];

# Submit for removal
my $response = $session->remove( $desired_whitelist );
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
 Apply the following attributes to search for a specific Infoblox::Grid::ThreatAnalytics::WhiteList
object.
  fqdn    - Optional. The Grid Threat Analytics White List FQDN.
  status  - Optional. The Grid Threat Analytics White List status.
  comment - Optional. The Grid Threat Analytics White List comment.
```

Example

```
my @retrieved_objs = $session->search(
    'object' => 'Infoblox::Grid::ThreatAnalytics::WhiteList',
    'fqdn'   => 'test.*',
);
```

METHODS

comment( )

Use this method to set or retrieve Grid Threat Analytics White List comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is desired comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $whitelist->comment();

#Modify comment
$whitelist->comment('new comment');
```

disable( )

Use this method to disable or enable Grid Threat Analytics White List.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to disable Grid Threat Analytics White List or 'false' to enable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Exmaple

```
#Get disable
my $disable = $whitelist->disable();

#Modify disable
$whitelist->disable('true');
```

fqdn( )

Use this method to set or retrieve a fully-qualified domain name (FQDN) of the Grid Threat Analytics White List.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired FQDN in string format.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Exmaple

```
#Get fqdn
my $fqdn = $whitelist->fqdn();

#Modify fqdn
$whitelist->fqdn('test2.com');
```

status( )

Use this method to retrieve the status of Grid Threat Analytics White List. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is 'CUSTOM', 'BOTH' or 'SYSTEM'.

Example

```
#Get status
my $status = $whitelist->status();
```

NAME

Infoblox::Grid::ThreatInsight::CloudClient - Grid Threat Insight Cloud Client object.

DESCRIPTION

Use this object to configure the cloud client that is used for integrating with Infoblox Threat Insight in the cloud.

SESSION METHODS

The following functions can be applied to a Infoblox::Grid::ThreatInsight::CloudClient object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatInsight::CloudClient',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify some of the attributes of the object.
$object->enable('true');

# Submit modification
my $response = $session->modify($object);
```

METHODS

This section describes all the methods that you can use to configure and retrieve values of the Grid Threat Insight Cloud Client object.

blacklist_rpz_list( )

Use this method to set or retrieve the list of RPZs to which domains detected by the Threat Insight Cloud Client are targeted.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::DNS::Zone objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get blacklist_rpz_list value
my $blacklist_rpz_list = $object->blacklist_rpz_list();

#Modify blacklist_rpz_list value
$object->blacklist_rpz_list([$rpz_zone]);
```

enable( )

Use this method to set or retrieve the flag that indicates whether Threat Insight on the Cloud Client is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the Threat Insight in the Cloud Client and 'false' to disable it. The default is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable value
my $enable = $object->enable();

#Modify enable value
$object->enable('true');
```

force_refresh( )

Use this method to set the flag that indicates whether force refresh for Response Policy Zones is enabled. This is a write-only attribute.

Note that force refresh takes effect only if at least one new Response Policy Zone is configured. Otherwise, the corresponding CLI command is used.

Parameter

Specify 'true' to enable force refresh for the Response Policy Zone and 'false' to disable it. The default is 'true'.

Parameter

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify force_refresh value
$object->force_refresh('false');
```

interval( )

Use this method to set or retrieve the time interval (in seconds) for the Threat Insight Cloud Client integration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 60 and 3600. The default value is 600.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interval value
my $interval = $object->interval();

#Modify interval value
$object->interval(3000);
```

NAME

Infoblox::Grid::ThreatProtection - Grid Threat Protection object.

DESCRIPTION

This object provides information about the Grid Threat protection settings.

SESSION METHODS

The following functions can be applied to a Grid::ThreatProtection object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid Threat Protection object
 object - Required. It must be set to "Infoblox::Grid::ThreatProtection".
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatProtection',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify some of the attributes of the retrieved_objs object.
$retrieved_objs->events_per_second_per_rule('2');
$retrieved_objs->rule_update_policy('MANUAL');
# Submit modification
my $response = $session->modify( $retrieved_objs );
```

METHODS

This section describes all the methods that you can use to configure and retrieve values of the Threat Protection object.

current_ruleset( )

Use this method to set or retrieve the current Grid ruleset.

Parameter

Valid value is an Infoblox::Grid::ThreatProtection::Ruleset object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $obj->current_ruleset();
#Modify attribute value
$obj->current_ruleset($rs);
```

enable_nat_rules( )

Use this method to enable or disable the NAT Threat Protection feature.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Paramter

Specify 'true' to enable NAT mapping support for threat protection or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->enable_nat_rules();

#Modify attribute value
$object->enable_nat_rules('true');
```

events_per_second_per_rule( )

Use this method to set or retrieve the number of events logged per second per rule.

Parameter

The number of events logged per second per rule in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->events_per_second_per_rule();
# Modify attribute value
$object->events_per_second_per_rule('2');
```

enable_auto_download( )

Use this method to enable or disable the auto download service.

Parameter

Specify 'true' to enable the auto download service or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $obj->enable_auto_download();
#Modify attribute value
$obj->enable_auto_download('true');
```

enable_scheduled_download( )

Use this method to enable or disable the scheduled download. The default frequency is once every 24 hours if it is disabled.

Parameter

Specify 'true' to enable the scheduled download or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $obj->enable_scheduled_download();
#Modify attribute value
$obj->enable_scheduled_download('true');
```

rule_update_policy( )

Use this method to set or retrieve the updated rule policy.

Parameter

Valid value is 'AUTOMATIC' or 'MANUAL'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->rule_update_policy();
# Modify attribute value
$object->rule_update_policy('MANUAL');
```

last_checked_for_update( )

Use this method to retrieve the time when the Grid last checked for updates.

Parameter

None

Returns

The method returns the attribute value, the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
# Get attribute value
my $value = $object->last_checked_for_update();
```

last_rule_update_version( )

Use this method to retrieve the last rule update version. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->last_rule_update_version();
```

nat_rules( )

Use this method to set or retrieve the list of NAT mapping rules for threat protection.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::ThreatProtection::NATRule objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $obj->nat_rules();
#Modify attribute value
$obj->nat_rules($nat_rules);
```

scheduled_download( )

Use this method to set or retrieve the schedule setting for automatic rule update.

Parameter

Valid value is an Infoblox::Grid::ScheduleSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $obj->scheduled_download();
#Modify attribute value
$obj->scheduled_download($schedule);
```

test_threat_protection_server_connectivity( )

Use this method ot test the connectivity with the Infoblox threat protection server.

Key Reference

None

Returns

The method returns an Infoblox::Grid::TestResult object if connectivity test occurs and 0 otherwise.

Example

```
my $res = $obj->test_threat_protection_server_connectivity();
```

disable_multiple_dns_tcp_request( )

Use this method to disable multiple BIND responses via TCP connection.

Parameter

Set the parameter to "true" to disable multiple TCP requests. Set the parameter to "false" to enable multiple TCP requests.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->disable_multiple_dns_tcp_request();
# Modify attribute value
$object->disable_multiple_dns_tcp_request('true');
```

NAME

Infoblox::Grid::ThreatProtection::NATPort - a NAT Threat Protection Port object.

DESCRIPTION

The Threat Protection NAT Port object provides information about the port blocks configured for NAT mapping.

CONSTRUCTION

```
my $nat_port = Infoblox::Grid::ThreatProtection::NATPort->new(
   start_port => $uint, #Required
   end_port   => $uint, #Required
   block_size => $uint, #Required
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions are available to apply to a NAT Port object.

Infoblox::Grid::ThreatProtection::NATRule->nat_ports( )

Use this method to set or retrieve NAT Port configuration for the NAT Threat Protection Rule. See Infoblox::Grid::ThreatProtection::NATRule->nat_ports() for parameters and return values.

Example

```
#Get nat_ports
my $nat_ports = $nat_rule->nat_ports();

#Modify nat_ports
$nat_rule->nat_ports($nat_ports);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Threat Protection NAT Port.

block_size( )

Use this method to set or retrieve the block size for the NAT Port configuration object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->block_size();

#Modify attribute value
$object->block_size(20);
```

end_port( )

Use this method to set or retrieve the end port value for the NAT port configuration object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->end_port();

#Modify attribute value
$object->end_port(10);
```

start_port( )

Use this method to set or retrieve the start port value for the NAT port configuration object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->start_port();

#Modify attribute value
$object->start_port(5);
```

NAME

Infoblox::Grid::ThreatProtection::NATRule - a NAT Threat Protection Rule object.

DESCRIPTION

The NAT Threat Protection Rule object provides information about NAT rules configured for the threat protection NAT mapping feature.

CONSTRUCTOR

```
my $nat_rule = Infoblox::Grid::ThreatProtection::NATRule->new(
    rule_type     => 'ADDRESS' | 'NETWORK' | 'RANGE', #Required
    address       => $ipaddress,                      #Required if rule_type is 'ADDRESS'
    network       => $ipaddress,                      #Required if rule_type is 'NETWORK'
    cidr          => $uint,                           #Required if rule_type is 'NETWORK'
    start_address => $ipaddress,                      #Required if rule_type is 'RANGE'
    end_address   => $ipaddress,                      #Required if rule_type is 'RANGE'
    nat_ports     => $nat_ports,                      #Optional
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions are available to apply to a NAT Port object.

Infoblox::Grid::ThreatProtection->nat_rules( )

Use this method to set or retrieve the list of rules configured for the threat protection NAT mapping feature. See Infoblox::Grid::ThreatProtection->nat_rules() for parameters and return values.

Example

```
#Get nat_rules
my $nat_rules = $nat_rule->nat_rules();

#Modify nat_rules
$nat_rule->nat_rules($nat_rules);
```

Infoblox::Grid::Member::ThreatProtection->nat_rules( )

Use this method to set or retrieve the list of rules configured for the threat protection NAT mapping feature. See Infoblox::Grid::Member::ThreatProtection->nat_rules() for parameters and return values.

Example

```
#Get nat_rules
my $nat_rules = $nat_rule->nat_rules();

#Modify nat_rules
$nat_rule->nat_rules($nat_rules);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Threat Protection NAT Port.

address( )

Use this method to set or retrieve the IP address for the threat protection NAT mapping rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IP address in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->address();

#Modify attribute value
$object->address('1.1.1.1');
```

cidr( )

Use this method to set or retrieve the network CIDR for the threat protection NAT mapping rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->cidr();

#Modify attribute value
$object->cidr(8);
```

end_address( )

Use this method to set or retrieve the end address for the range of the threat protection NAT mapping rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IP address in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->end_address();
```

```
#Modify attribute value
$object->end_address('1.1.0.255');
```

nat_ports( )

Use this method to set or retrieve the NAT port configuration for the threat protection NAT mapping rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::Grid::ThreatProtection::NATPort objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->nat_ports();

#Modify attribute value
$object->nat_ports($nat_ports);
```

network( )

Use this method to set or retrieve the network address for the threat protection NAT mapping rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->network();

#Modify attribute value
$object->network('10.0.0.0');
```

rule_type( )

Use this method to set or retrieve the rule type for the threat protection NAT mapping rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'ADDRESS', 'RANGE', 'NETWORK'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->rule_type();

#Modify attribute value
$object->rule_type('RANGE');
```

start_address( )

Use this method to set or retrieve the start address of the range for the threat protection NAT mapping rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IP address in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $object->start_address();

#Modify attribute value
$object->start_address('1.1.0.255');
```

NAME

Infoblox::Grid::ThreatProtection::Profile - Threat Protection profile object.

DESCRIPTION

The Threat Protection profile object facilitates configuring groups of Threat Protection members that have similar traffic properties. A member can be either associated with a Threat Protection profile or inherit the ruleset from the Grid or override the ruleset individually at the member level.

CONSTRUCTOR

```
 my $object = Infoblox::Grid::ThreatProtection::Profile->new(
     name                                    => $string,
#Required
     comment                                 => $string,
#Optional / Default is undefined
     current_ruleset                         => $ruleset,
#Optional / Default is undefined
     disable_multiple_dns_tcp_request        => 'true' | 'false',
#Optional / Default is 'true'
     events_per_second_per_rule              => $uint,
#Optional / Default is undefined
     extattrs                                => { $string => $extattr, ... },
#Optional / Default is undefined
     extensible_attributes                   => {$string => $string | $num, $string => [ $string | $num,
... ], ... }, #Optional / Default is undefined
     members                                 => [$host_name | ... ],
#Optional / Default is empty list
     override_current_ruleset                => 'true' | 'false',
#Optional / Default is 'false'
     override_disable_multiple_dns_tcp_request => 'true' | 'false',
#Optional / Default is 'false'
     override_events_per_second_per_rule     => 'true' | 'false',
#Optional / Default is 'false'
     source                                  => $tp_member | $tp_profile,
#Optional / Default is undefined
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

The following functions can be applied to a Infoblox::Grid::ThreatProtection::Profile object.

Infoblox::Session->add( )

Use this method to add the object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct object
my $object = Infoblox::Grid::ThreatProtection::Profile->new(
    name => 'profile1',
);

#Submit object for addition
$session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Threat Protection profile object:

    name                  - Optional. The Threat Protection profile name.
    comment               - Optional. The Threat Protection profile comment.
    extattrs              - Optional. A hash reference containing Infoblox::Grid::Extattr object.
    extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatProtection::Profile',
    'name'   => 'profile1',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify events_per_second_per_rule value
$object->events_per_second_per_rule('2');

#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove the object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP range object, and then submit this object for removal.

Example

```
#Get the objects
my @retrieved_objs = $session->get(
    object => 'Infoblox::Grid::ThreatProtection::Profile',
    name   => 'profile1',
);

#Find the desired object from the retrieved list
my $desired_object = $retrieved_objs[0];

#Submit for removal
my $response = $session->remove($desired_object);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for the Threat Protection profile object:
```

```
name                  - Optional. The Threat Protection profile name (regular expression).
comment               - Optional. The Threat Protection profile comment (regular expression).
extattrs              - Optional. A hash reference containing Infoblox::Grid::Extattr object.
extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# search for objects
my @retrieved_objs = $session->search(
    object      => 'Infoblox::Grid::ThreatProtection::Profile',
    comment     => '.*comment',
);

# search for objects defining 'Santa Clara' for 'Site' extensible attribute
my @retrieved_objs = $session->search(
    object               => 'Infoblox::Grid::ThreatProtection::Profile',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

METHODS

This object provides information about the Threat Protection profile settings.

comment( )

Use this method to set or retrieve the Threat Protection profile descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is a desired comment in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $value = $object->comment();

#Modify comment value
$object->comment('new comment');
```

current_ruleset( )

Use this method to set or retrieve the current Threat Protection profile ruleset.

Setting this method to a defined value implicitly sets the override_current_ruleset method to 'true'. Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_current_ruleset attribute to 'false'.

Note that when current_ruleset is set to a defined value and override_dcurrent_ruleset is set to 'false', the last operation takes precedence. Thus the sequence $object->current_ruleset($rs); $object->override_current_ruleset('false'); will set override_current_ruleset to 'false', and the sequence $object->override_current_ruleset('false'); $object->current_ruleset($rs); will result in override_current_ruleset='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an Infoblox::Grid::ThreatProtection::Ruleset object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get current_ruleset value
my $value = $object->current_ruleset();
```

```
#Modify current_ruleset value
$object->current_ruleset($rs);
```

disable_multiple_dns_tcp_request( )

Use this method to disable multiple BIND responses via TCP connection.

Setting this method to a defined value implicitly sets the override_disable_multiple_dns_tcp_request method to 'true'. Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_disable_multiple_dns_tcp_request attribute to 'false'.

Note that when config is set to a defined value and override_disable_multiple_dns_tcp_request is set to 'false', the last operation takes precedence. Thus the sequence $object->disable_multiple_dns_tcp_request($value); $object->override_disable_multiple_dns_tcp_request('false'); will set override_disable_multiple_dns_tcp_request to 'false', and the sequence $object->override_disable_multiple_dns_tcp_request('false'); $object->disable_multiple_dns_tcp_request($value); will result in override_disable_multiple_dns_tcp_request='true'.

Parameter

Set the parameter to 'true' to disable multiple TCP requests. Set the parameter to 'false' to enable multiple TCP requests.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->disable_multiple_dns_tcp_request();
# Modify attribute value
$object->disable_multiple_dns_tcp_request('true');
```

events_per_second_per_rule( )

Use this method to set or retrieve the number of events logged per second per rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of events logged per second per rule in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get events_per_second_per_rule value
my $value = $object->events_per_second_per_rule();

#Modify events_per_second_per_rule value
$object->events_per_second_per_rule('2');
```

extattrs( )

Use this method to set or retrieve the extensible attributes that are associated with a Threat Protection profile object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is a hash reference that contains the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs value
```

```
my $value = $object->extattrs();

#Modify extattrs value
$object->extattrs({'Site' => $extattr1, 'Administrator' => $extattr2});
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes that are associated with a Threat Protection profile object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes value
my $value = $object->extensible_attributes();

#Modify extensible attributes value
$object->extensible_attributes({'Site' => 'Santa Clara', 'Administrator' => ['Peter', 'Tom']});
```

members( )

Use this method to set or retrieve the list of members that are using the Threat Protection profile.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains desired Threat Protection member names in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get members value
my $value = $object->members();

#Modify members value
$object->members(['infoblox.localdomain']);
```

name( )

Use this method to retrieve a Threat Protection profile name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired Threat Protection profile name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $value = $object->name();

#Modify name value
$object->name('new_name');
```

override_events_per_second_per_rule( )

Use this method to set or retrieve the override flag for the number of events logged per second per rule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to set the override_events_per_second_per_rule flag or 'false' to deactivate/unset it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_events_per_second_per_rule value
my $value = $object->override_events_per_second_per_rule();

#Modify override_events_per_second_per_rule value
$object->override_events_per_second_per_rule('true');
```

override_current_ruleset( )

The override_current_ruleset attribute controls whether the current ruleset value is used for Threat Protection profile instead of the Grid default.

The override_current_ruleset attribute can be specified explicitly. It is also set implicitly when current_ruleset is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to set the override_current_ruleset flag or 'false' to deactivate/unset it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_current_ruleset value
my $override = $object->override_current_ruleset();

#Modify override_current_ruleset
$object->override_current_ruleset('true');
```

override_disable_multiple_dns_tcp_request( )

The override_disable_multiple_dns_tcp_request attribute controls whether the Threat Protection profile disable_multiple_dns_tcp_request value is used instead of the Grid default.

The override_disable_multiple_dns_tcp_request attribute can be specified explicitly. It is also set implicitly when disable_multiple_dns_tcp_request is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to set the override_disable_multiple_dns_tcp_request flag or 'false' to unset it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_disable_multiple_dns_tcp_request value
my $value = $object->override_disable_multiple_dns_tcp_request();

#Modify override_disable_multiple_dns_tcp_request value
$object->override_disable_multiple_dns_tcp_request('true');
```

source( )

Use this method to set the source for cloning the profile settings. This is a write-only attribute and can be used only on create operation.

Include the specified parameter to set the attribute value.

Parameter

The valid value is an Infoblox::Grid::Member::ThreatProtection or Infoblox::Grid::ThreatProtection::Profile object reference.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify source value
$object->source($profile1);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a Threat Protection profile insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
               );

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a Threat Protection profile

```
my $atp_profile = Infoblox::Grid::ThreatProtection::Profile->new(
               name    => "atp_profile1",
               comment => "add TP profile",
               );

unless ($atp_profile) {
       die("Construct Threat Protection profile failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}

#Add the Threat Protection profile object to the Infoblox appliance through a session
$session->add($atp_profile)
       or die("Add Threat Protection profile failed: ",
                       $session->status_code() . ":" . $session->status_detail());
print "Threat Protection profile object added to server successfully\n";
```

#Search for a specific Threat Protection profile

```
#Search all Threat Protection profiles that matches "atp"
my @retrieved_objs = $session->search(
               object => "Infoblox::Grid::ThreatProtection::Profile",
               name   => 'atp'
               );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search Threat Protection profile failed: ",
               $session->status_code() . ":" . $session->status_detail());
}
print "Search Threat Protection profile object found at least 1 matching entry\n";
```

#Get and modify a Threat Protection profile

```
#Get a Threat Protection profile through the session
my @retrieved_objs = $session->get(
               object => "Infoblox::Grid::ThreatProtection::Profile",
               name   => "atp_profile1"
               );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Get Threat Protection profile failed: ",
               $session->status_code() . ":" . $session->status_detail());
}
print "Get Threat Protection profile object found at least 1 matching entry\n";

#Modify one of the attributes of the specified Threat Protection profile
$object->comment("this is new comment");

#Apply the changes
$session->modify($object)
       or die("Modify Threat Protection profile failed: ",
               $session->status_code() . ":" . $session->status_detail());
print "Threat Protection profile object modified successfully \n";
```

#Remove a Threat Protection profile

```
#Get Threat Protection profile through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::ThreatProtection::Profile",
    name   => "atp_profile1"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get Threat Protection profile failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Threat Protection profile object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
       or die("Remove Threat Protection profile failed: ",
               $session->status_code() . ":" . $session->status_detail());
print "Threat Protection profile object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::ThreatProtection::Profile::Rule - Threat Protection profile rule object.

DESCRIPTION

This object provides information about the Threat Protection profile rule settings.

SESSION METHODS

The following functions can be applied to a Infoblox::Grid::ThreatProtection::Profile::Rule object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Threat Protection profile rule object.

 sid     - Optional. The Rule ID.
 rule    - Optional. The Threat Protection rule object.
 profile - Optional. The Threat Protection profile object.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatProtection::Profile::Rule',
    'sid'    => '211111'
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
 my $rule = $session->search('object' => 'Infoblox::Grid::ThreatProtection::Rule', 'sid' =>
'211111');
 my $object = $session->search('object' => 'Infoblox::Grid::ThreatProtection::Profile::Rule', 'rule'
=> $rule);

 my $conf = $object->config();
 $conf->action('PASS');

 # Use this method to modify attributes of object.
 $object->disable('true');
 $object->override_disable('true');
 $object->config($conf);
```

```
$object->override_config('true');
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid Threat Protection::Rule object.

 sid     - Optional. The Rule ID.
 rule    - Optional. The Threat Protection rule object.
 profile - Optional. The Threat Protection profile object.
```

Example

```
#Retrieve the Threat Protection rule from appliance
my $rule = $session->search(
    'object' => 'Infoblox::Grid::ThreatProtection::Rule',
    'sid'    => '211111',
);

my $object = $session->search(
    'object' => 'Infoblox::Grid::ThreatProtection::Profile::Rule',
    'rule'   => $rule,
);
```

METHODS

This object provides information about the Threat Protection profile rule settings.

config( )

Use this method to set or retrieve the rule configuration information.

Setting this method to a defined value implicitly sets the override_config method to 'true'. Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_config attribute to 'false'.

Note that when config is set to a defined value and override_config is set to 'false', the last operation takes precedence. Thus the sequence $object->config($value); $object->override_config('false'); will set override_config to 'false', and the sequence $object->override_config('false'); $object->config($value); will result in override_config='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is reference on Infoblox::Grid::ThreatProtection::RuleConfig object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get config value
my $value = $object->config();

#Modify config value
$value->log_severity('INFORMATIONAL');
$object->config($value);
```

disable( )

Use this method to set or indicate whether the Threat Protection profile rule is disabled.

Setting this method to a defined value implicitly sets the override_disable method to 'true'. Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_disable attribute to 'false'.

Note that when disable is set to a defined value and override_disable is set to 'false', the last operation takes precedence. Thus the sequence $object->disable('true'); $object->override_disable('false'); will set override_disable to 'false', and the sequence $object->override_disable('false'); $object->disable('true'); will result in override_disable='true'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to disable Threat Protection profile rule and 'false' to enable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable value
my $value = $object->disable();

#Modify disable value
$object->disable('true');
```

override_config( )

The override_config attribute controls whether the current config value is used for the Threat Protection profile rule instead of the Grid default.

The override_config attribute can be specified explicitly. It is also set implicitly when config is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to set the override_config flag or 'false' to deactivate/unset it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_config value
my $value = $object->override_config();

#Modify override_config value
$object->override_config('true');
```

override_disable( )

The override_disable attribute controls whether the current disable value is used for the Threat Protection profile rule instead of the Grid default.

The override_disable attribute can be specified explicitly. It is also set implicitly when disable is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to set the override_disable flag or 'false' to deactivate/unset it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_disable value
my $value = $object->override_disable();

#Modify override_disable value
$object->override_disable('true');
```

profile( )

Use this method to retrieve the Threat Protection profile object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value, an Infoblox::Grid::ThreatProtection::Profile object.

Example

```
#Get profile value
my $value = $object->profile();
```

rule( )

Use this method to retrieve the Threat Protection rule object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value, an Infoblox::Grid::ThreatProtection::Rule object.

Example

```
#Get rule value
my $value = $object->rule();
```

sid( )

Use this method to retrieve the Rule ID. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get sid value
my $value = $object->sid();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a Threat Protection profile rule insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
              master   => "192.168.1.2", #appliance host ip
              username => "admin",       #appliance user login
              password => "infoblox"     #appliance password
              );

unless ($session) {
       die("Construct session failed: ",
              Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a Threat Protection profile
```

```
my $atp_profile = Infoblox::Grid::ThreatProtection::Profile->new(
                name    => "atp_profile1",
                comment => "add TP profile",
                );

unless ($atp_profile) {
       die("Construct Threat Protection profile failed: ",
                Infoblox::status_code() . ":" . Infoblox::status_detail());
}

#Add the Threat Protection profile object to the Infoblox appliance through a session
$session->add($atp_profile)
       or die("Add Threat Protection profile failed: ",
                        $session->status_code() . ":" . $session->status_detail());
print "Threat Protection profile object added to server successfully\n";
```

#Search for a specific Threat Protection profile rule

```
#Search all Threat Protection profile rules that matches "atp_profile1" profile
my @retrieved_objs = $session->search(
                object  => "Infoblox::Grid::ThreatProtection::Profile::Rule",
                profile => $atp_profile,
                );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search Threat Protection profile rule failed: ",
                $session->status_code() . ":" . $session->status_detail());
}
print "Search Threat Protection profile rule object found at least 1 matching entry\n";
```

#Get and modify a Threat Protection profile rule

```
#Get a Threat Protection profile rule through the session
my @retrieved_objs = $session->get(
                object  => "Infoblox::Grid::ThreatProtection::Profile::Rule",
                profile => $atp_profile,
                );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Get Threat Protection profile rule failed: ",
                $session->status_code() . ":" . $session->status_detail());
}
print "Get Threat Protection profile rule object found at least 1 matching entry\n";

#Modify one of the attributes of the specified Threat Protection profile rule
$object->disable("true");

#Apply the changes
$session->modify($object)
       or die("Modify Threat Protection profile rule failed: ",
                $session->status_code() . ":" . $session->status_detail());
print "Threat Protection profile rule object modified successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::Grid::ThreatProtection::Rule - Grid Threat Protection Rule object.

DESCRIPTION

This object provides information about the Grid Threat protection rule settings.

CONSTRUCTOR

```
my $object = Infoblox::Grid::ThreatProtection::Rule->new(
    'comment'     => $string                                    # Optional
    'disable'     => 'true' | 'false',                          # Optional / Default is 'false'
    'config'      => $config,                                   # Required
    'template'    => $template,                                 # Required
);
```

SESSION METHODS

The following functions can be applied to a Grid::ThreatProtection::Rule object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
    #Get Rule template Object
    my $template = $session->search('object' => 'Infoblox::Grid::ThreatProtection::RuleTemplate', 'name'
  => 'Whitelist source IPv6 address');
    my $config = $template->default_config();
    my $params = $config->params();
    $params->[0]->value('2001::1');
    #Construct an object
    my $custom_rule = Infoblox::Grid::ThreatProtection::Rule->new(
                      'template'    => $template,
                      'comment'     => 'Test Custom Rule',
                      'config'      => $config,
                      'disable'     => 'false');

    #Submit for addition
    my $response = $session->add( $custom_rule );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid Threat Protection::Rule object.
 sid    - Optional. The Rule ID.
 name   - Optional. The name of Threat Protection Rule.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatProtection::Rule',
    'name' => 'Whitelist source IPv6 address',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
my $modify_rule_template = $session->search('object' =>
'Infoblox::Grid::ThreatProtection::RuleTemplate', 'name' => 'Whitelist source IP address');
my $config = $modify_rule_template->default_config();
$conf->action('PASS');
# Use this method to modify attributes of object.
$retrieved_objs->comment('Comment of Custom Rule');
$retrieved_objs->disable('true');
$retrieved_objs->config($config);
$retrieved_objs->template($modify_rule_template);
# Submit modification
my $response = $session->modify( $retrieved_objs );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatProtection::Rule',
    'name' => 'Whitelist source IPv6 address',
);
#Find the desired object from the retrieved list.
my $desired_object = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_object );
```

Infoblox::Session->ruleset( )

Use this method to retrieve the ruleset. See Infoblox::Session->add() for parameters and return values.

Example

```
#Get the object
my $rule = $self->{'session'}->search(
    'object' => 'Infoblox::Grid::ThreatProtection::Rule',
    'sid' => '111111',
);

# Retrieve ruleset
my $ruleset = $rule->ruleset();
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid Threat Protection::Rule object.
```

```
sid    - Optional. The Rule ID.
name   - Optional. The name of Threat Protection Rule.
```

Example

```
my @retrieved_objs = $session->search(
    'object' => 'Infoblox::Grid::ThreatProtection::Rule',
    'name' = 'Whitelist source IP network';
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve values of the Threat Protection Rule.

allowed_actions( )

Use this method to retrieve the allowed actions for the rule. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->allowed_actions();
```

category( )

Use this method to retrieve reference to the rule category. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->category();
```

comment( )

Use this method to set or retrieve user editable comments.

Parameter

Comments in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->comment();
# Modify attribute value
$object->comment('New comment');
```

config( )

Use this method to set or retrieve information about the rule configuration.

This method is required for creating custom rules. The server will set all undefined members of the object to include the 'params' array from the template.

Parameter

Valid value is reference on Infoblox::Grid::ThreatProtection::RuleConfig object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->config();
$value->log_severity('INFORMATIONAL');
# Modify attribute value
$object->config($value);
```

description( )

Use this method to retrieve the description for the rule. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->description();
```

disable( )

Use this method to set or indicate whether the rule is enabled or disabled for the Grid.

Parameter

Valid value is "true" or "false". The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->disable();
# Modify attribute value
$object->disable('true');
```

is_factory_reset_enabled( )

Use this method to retrieve the flag that indicates whether the factory reset of this object is enabled or disabled. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->is_factory_reset_enabled();
```

name( )

Use this method to retrieve the rule name. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->name();
```

sid( )

Use this method to retrieve the Rule ID. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->sid();
```

template( )

Use this method to set or retrieve reference to the template object.

Parameter

Valid value is reference on Infoblox::Grid::ThreatProtection::RuleTemplate object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->template();
# Get Rule Template Object.
my $modify_rule_template = $session->search('object' =>
'Infoblox::Grid::ThreatProtection::RuleTemplate', 'name' => 'Whitelist source IP network');
$object->template($modify_rule_template);
# Submit modification
my $response = $session->modify( $object );
```

type( )

Use this method to retrieve the rule type. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->type();
```

NAME

Infoblox::Grid::ThreatProtection::RuleCategory - The rule category settings.

DESCRIPTION

This object provides information about the rule category settings.

SESSION METHODS

The following functions can be applied to a Grid::ThreatProtection::RuleCategory object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Rule Category object.
 name   - Optional. The name of the Rule Category object.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatProtection::RuleCategory',
    'name' => 'Whitelist source IP address',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Rule Category object.
 name   - Optional. The name of the Rule Category object.
```

Example

```
my @retrieved_objs = $session->search(
    'object' => 'Infoblox::Grid::ThreatProtection::RuleCategory',
    'name' => 'Whitelist source IP address',
);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the struct.

is_factory_reset_enabled( )

Use this method to retrieve the flag that indicates whether the factory reset of this object is enabled or disabled. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->is_factory_reset_enabled();
```

name( )

Use this method to retrieve the category name. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->name();
```

NAME

Infoblox::Grid::ThreatProtection::RuleConfig - The rule configuration.

DESCRIPTION

This is an in-memory struct.

CONSTRUCTOR

```
my $object = Infoblox::Grid::ThreatProtection::RuleConfig->new(
    'action'          => 'ALERT' | 'PASS' | 'DROP',                              # optional
    'log_severity'    => 'CRITICAL' | 'MAJOR' | 'WARNING' | 'INFORMATIONAL',     # optional
    'params'          => [$param1, $param2, ...],                                # required
);
```

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the struct.

action( )

Use this method to set or retrieve the action of the rule.

Parameter

Valid value is 'ALERT', 'PASS' or 'DROP'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->action();
# Modify attribute value
$object->action('DROP');
```

log_severity( )

Use this method to set or retrieve the severity for the rule log.

Parameter

Valid value is 'CRITICAL', 'MAJOR', 'WARNING' or 'INFORMATIONAL'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->log_severity();
# Modify attribute value
$object->log_severity('WARNING');
```

params( )

Use this method to set or retrieve rule parameters.

Parameter

Valid value is an array that contains Infoblox::Grid::ThreatProtection::RuleParam structs.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->params();

# create expected RuleParam struct
my $param = Infoblox::Grid::ThreatProtection::RuleParam->new(
    'name' => 'SRC_IP',
    'value' => 'abcd::/64',
);

# Modify attribute value
$object->params([$param]);
```

NAME

Infoblox::Grid::ThreatProtection::RuleParam - A Grid Threat Protection Rule parameter object.

DESCRIPTION

The Grid Threat Protection Rule parameter object represents information about Threat Protection Rule Config parameters.

CONSTRUCTOR

```
my $object = Infoblox::Grid::ThreatProtection::RuleParam->new(
    'name'  => $string,     # Required
    'value' => $string,     # Required
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

This section describes all the functions that you can apply to an ThreatProtection RuleParam object.

Infoblox::Grid::ThreatProtection::RuleConfig->params( )

Use this method to set or retrieve rule parameters. See Infoblox::Grid::ThreatProtection::RuleConfig->params()

Example

```
my $rule_param = Infoblox::Grid::ThreatProtection::RuleParam->new(
  'name'  => 'SRC_IP',
  'value' => 'abcd::',
);

my $rule_config = Infoblox::Grid::ThreatProtection::RuleConfig->new(
  'action'              => 'PASS',
  'log_severity'        => 'MAJOR',
  'params'              => [$rule_param]);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the struct.

description( )

Use this method to retrieve the parameter description. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->description();
```

min( )

Use this method to retrieve the minimum value of the parameter if the parameter syntax is UNSIGNED_INT. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->min();
```

max( )

Use this method to retrieve the maximum value of the parameter if the parameter syntax is UNSIGNED_INT. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->max();
```

name( )

Use this method to set or retrieve the parameter name.

Parameter

The parameter name in string format.

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->name();
# Modify attribute value
$object->name('SRC_IP');
```

read_only( )

Use this method to indicate if the parameter is read-only. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->read_only();
```

syntax( )

Use this method to retrieve the parameter syntax. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->syntax();
```

value( )

Use this method to set or retrieve the parameter value.

Parameter

The parameter value in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->value();
# Modify attribute value
$object->value('15');
```

NAME

Infoblox::Grid::ThreatProtection::Ruleset - A Grid Threat Protection Ruleset object.

DESCRIPTION

This object represents the Grid Threat Protection ruleset.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a Grid ruleset object.

Infoblox::Session->get( )

Use this method to retrieve all the ruleset objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatProtection::Ruleset',
);
```

Infoblox::Session->search( )

Use this method to retrieve all the ruleset objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Example

```
my @retrieved_objs = $session->search(
    'object' => 'Infoblox::Grid::ThreatProtection::Ruleset',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

If you have applied an access control list to an object, you must restart services after you update the access control list for the changes to take effect. See Infoblox::Session->restart() method.

Example

```
# Use this method to modify comments for the Grid member.
$ruleset->comment("This is modified object");
# Submit modification
my $response = $session->modify( $ruleset );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Submit for removal
my $response = $session->remove( $desired_ruleset );
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the struct.

add_type( )

Use this method to retrieve how the ruleset was added. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value, which is either "AUTOMATIC" or "MANUAL".

Example

```
# Get attribute value
my $value = $object->add_type();
```

added_time( )

Use this method to retrieve the time when the ruleset was added. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value, the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
# Get attribute value
my $value = $object->added_time();
```

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $object->comment();
#Modify comment
$object->comment("Modified comment");
```

do_not_delete( )

Use this method to set or retrieve the do_not_delete attribute of the ruleset. If set to "true", the ruleset will not be deleted during a ruleset upgrade.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value, which is "true" or "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get do_not_delete from the ruleset
my $do_not_delete = $object->do_not_delete();
#Modify do_not_delete
$object->do_not_delete("true");
```

is_factory_reset_enabled( )

Use this method to retrieve the flag that indicates whether the factory reset of this object is enabled or disabled. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->is_factory_reset_enabled();
```

used_by( )

Use this method to retrieve the users of the ruleset. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value, which is a list of strings.

Example

```
# Get attribute value
my $value = $object->used_by();
```

version( )

Use this method to retrieve the ruleset version. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->version();
```

NAME

Infoblox::Grid::ThreatProtection::RuleTemplate - Grid Threat Protection Rule Template object.

DESCRIPTION

This object provides information about the Grid Threat protection rule template settings.

CONSTRUCTOR

```
my $object = Infoblox::Grid::ThreatProtection::RuleTemplate->new(
   'name' => $string,        # Required
);
```

SESSION METHODS

The following functions can be applied to a Grid::ThreatProtection::RuleTemplate object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid Threat Protection RuleTemplate object.
 sid    - Optional. The Rule ID.
 name   - Optional. The name of the Threat protection rule template.
```

Example

```
my @retrieved_objs = $session->get(
    'object' => 'Infoblox::Grid::ThreatProtection::RuleTemplate',
    'name' => 'Whitelist source IP network',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Grid Threat Protection::RuleTemplate object.
 sid     - Optional. The Rule ID.
 name    - Optional. The name of the Threat protection rule template.
 ruleset - Optional. An
L<Infoblox::Grid::ThreatProtection::Ruleset|Infoblox::Grid::ThreatProtection::Ruleset> object
representing a reference to the ruleset object.
```

Example

```
my @retrieved_objs = $session->search(
    'object' => 'Infoblox::Grid::ThreatProtection::RuleTemplate',
    'name' => 'Whitelist source IP network',
);
```

METHODS

allowed_actions( )

Use this method to retrieve allowed actions for the rule template. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->allowed_actions();
```

category( )

Use this method to retrieve reference to the rule category. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->category();
```

default_config( )

Use this method to retrieve default rule configuration information. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->default_config();
```

description( )

Use this method to retrieve the description for the rule template. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->description();
```

name( )

Use this method to set or retrieve the name for the rule template. This is a read-only attribute if the object was retrieved from the server.

Parameter

The name in string format.

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->name();
# Modify attribute value
$object->name('Whitelist source IP network');
```

ruleset( )

Use this method to retrieve a reference to the ruleset object. This is a read-only attribute.

Parameter

None

Returns

An Infoblox::Grid::ThreatProtection::Ruleset object.

Example

```
#Get ruleset value
my $value = $object->ruleset();
```

sid( )

Use this method to retrieve the Rule ID. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->sid();
```

versions( )

Use this method to retrieve information about the rule version. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->versions();
```

NAME

Infoblox::Grid::ThreatProtection::StatInfo - Statistics information.

DESCRIPTION

This is an in-memory struct.

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the struct.

critical( )

Use this method to retrieve the number of critical events. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->critical();
```

informational( )

Use this method to retrieve the number of informational events. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->informational();
```

major( )

Use this method to retrieve the number of major events. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->major();
```

timestamp( )

Use this method to retrieve the timestamp when the following data is being collected. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->timestamp();
```

warning( )

Use this method to retrieve the number of warning events. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->warning();
```

NAME

Infoblox::Grid::ThreatProtection::Statistics - Threat protection statistics.

DESCRIPTION

This object provides information about Threat protection statistics.

SESSION METHODS

The following functions can be applied to a Grid::ThreatProtection::Statistics object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Threat Protection Statistics object.
 grid_member   - Optional. The Grid member name.
```

Example

```
my @retrieved_objs = $session->get(
    'object'      => 'Infoblox::Grid::ThreatProtection::Statistics',
    'grid_member' => 'member.com',
);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Threat Protection Statistics object.
 grid_member   - Optional. The Grid member name.
```

Example

```
my @retrieved_objs = $session->search(
    'object'      => 'Infoblox::Grid::ThreatProtection::Statistics',
    'grid_member' => 'member.com',
);
```

METHODS

stat_infos( )

Use this method to retrieve event statistics. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be an array reference of Infoblox::Grid::ThreatProtection::StatInfo objects.

Example

```
# Get attribute value
my $value = $object->stat_infos();
```

grid_member( )

Use this method to retrieve a Grid member name. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->grid_member();
```

Infoblox::Grid::TimeZone - Grid time zone object.

- NAME
- DESCRIPTION
- CONSTRUCTOR
- SESSION METHODS
  - Infoblox::Session->get( )
  - Infoblox::Session->modify( )
- METHODS
  - ntp_enabled( )
  - time_zone( )
- SAMPLE CODE
- AUTHOR
- SEE ALSO
- COPYRIGHT

NAME

Infoblox::Grid::TimeZone - Grid time zone object.

DESCRIPTION

Grid TimeZone object is used to set the time zone for an Infoblox appliance.

CONSTRUCTOR

```
#Constructor for an Grid Time zone object
my $time_zone = Infoblox::Grid::TimeZone->new (
        time_zone     => $time_zone             #Required
        ntp_enabled   => "true" | "false"       #Optional / Default "false"
    );
```

SESSION METHODS

This section describes all the methods in Infoblox::Session that you can apply to a grid TimeZone object.

Infoblox::Session->get( )

Use this method to retrieve existing objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

Apply the following attributes to get a grid TimeZone object:

none.

Example

```
my @result_array = $session->get( "object" => "Infoblox::Grid::TimeZone");
```

Infoblox::Session->modify( )

Use this method to modify objects in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use method to modify the time zone.
$object->time_zone( "(UTC - 8:00) Pacific Time (US and Canada), Tijuana" );
$object->ntp_enabled( "false" );
# Submit modification
my $response = $session->modify( $object );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute value of a time zone.

ntp_enabled( )

Use this method to enable/disable NTP (Network Time Protocol).

Parameter

Specify "true" to enable NTP or "false" to disable it. Default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get ntp_enabled
my $enable = $object->ntp_enabled();
#Modify ntp_enabled
$object->ntp_enabled("true");
```

time_zone( )

Use this method to set or retrieve a time_zone.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired time in string format. Following are the available Time Zones:

```
'(UTC - 12:00)'
'(UTC - 11:00) Midway Island, Samoa'
'(UTC - 10:00) Hawaii'
'(UTC - 9:00) Alaska'
'(UTC - 8:00) Pacific Time (US and Canada), Tijuana'
'(UTC - 7:00) Arizona'
'(UTC - 7:00) Mountain Time (US and Canada)'
'(UTC - 6:00) Central Time (US and Canada)'
'(UTC - 6:00) Mexico City, Tegucigalpa'
'(UTC - 6:00) Saskatchewan'
'(UTC - 5:00) Bogota, Lima, Quito'
'(UTC - 5:00) Eastern Time (US and Canada)'

'(UTC + 12:00) Marshall Islands'
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get time_zone
my $time_zone = $object->time_zone();
#Modify time_zone
$object->time_zone("(UTC - 8:00) Pacific Time (US and Canada), Tijuana");
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to an object such as create, modify, and remove an object. This sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my @result_array = $session->get( "object" => "Infoblox::Grid::TimeZone");
if( defined @result_array  and scalar( @result_array ) > 0 )
 {
        my $object = $result_array[0];
        unless ($object) {
                die("Get on Time zone failed: ",
        $session->status_code() . ":" . $session->status_detail());
        }
#Modify time_zone
$object->time_zone("(UTC - 8:00) Pacific Time (US and Canada), Tijuana");
my $enable = $object->ntp_enabled();
$object->ntp_enabled( "true" );
$session->modify($object)
   or die("Modify on Time zone failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Grid Time zone modified successfully \n";
}
else
{
        print "No  TimeZone Structure found !!!\n";
}

####PROGRAM ENDS####

NAME

Infoblox::Grid::UpdatesDownloadMemberConfig - An Updates Download Member Configuration object.

DESCRIPTION

The Updates Download Member Configuration object provides information and settings for configuring Member that is responsible for updates download.

CONSTRUCTOR

```
my $http_proxy_setting = Infoblox::Grid::UpdatesDownloadMemberConfig->new(
    member    => $string | undef,                  #Required
    interface => 'ANY' | 'VIP' | 'LAN2' | 'MGMT', #Required
);
```

SESSION METHODS

The object does not support any session methods.

MODULE METHODS

The following functions are available to be applied to a Updates Download Member Configuration object.

Infoblox::Grid->updates_download_member_config( )

Use this method to set or retrieve the list of updates download member configurations. See Infoblox::Grid->updates_download_member_config() for parameters andreturn values.

Example

```
#Get updates_download_member_config value
my $updates_download_member_config = $grid->updates_download_member_config();

#Modify updates_download_member_config value
$grid->updates_download_member_config([$conf1, $conf2]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Updates Download Member Configuration object.

interface( )

Use this method to set or retrieve the source interface for updates download requests.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'ANY', 'VIP', 'LAN2' and 'MGMT'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get interface value
my $interface = $obj->interface();

#Modify interface value
$obj->interface('ANY');
```

is_online( )

Use this method to retrieve the flag that indicates whether the updates download member is on-line or not.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get is_online value
my $is_online = $obj->is_online();
```

member( )

Use this method to set or retrieve the updates download member name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired member's name in a string format or undef for Grid Master.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member value
my $member = $obj->member();

#Modify member value
$obj->member('desired-member.com');

#Modify member value to Grid Master
$obj->member(undef);
```

NAME

Infoblox::Grid::UpgradeGroup - Upgrade Group object.

DESCRIPTION

This object enables the configuration of upgrade groups for the Infoblox Grid.

CONSTRUCTOR

```
 my $group = Infoblox::Grid::UpgradeGroup->new(
         name                          => $string, #Required
         comment                       => $string, #Optional / Default is undefined
         distribution_policy           => "simultaneously" | "sequentially", #Optional / Default is
simultaneously
         upgrade_policy                => "simultaneously" | "sequentially", #Optional / Default is
simultaneously
         distribution_dependent_group  => $string, #Optional / Default is undefined
         upgrade_dependent_group       => $string, #Optional / Default is undefined
         distribution_time             => $timestamp, #See below
         upgrade_time                  => $timestamp, #See below
         members                       => [$m1, $m2, ...], #Optional / Default is undefined
 );
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to an Upgrade Group object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
       my $member1 = Infoblox::Grid::UpgradeGroup::Member->new(
                                                              member => '192.168.1.2',
                                                             );
       unless($member1) {
            die("Construct member failed: ",
                  Infoblox::status_code() . ":" . Infoblox::status_detail());
```

```
}
print "Member object created successfully\n";

#Create the upgrade group object with this member
my $sgu = Infoblox::Grid::UpgradeGroup->new(
                                            name                          => "groupname1",
                                            comment                       => "group name 1 comment",
                                            distribution_policy           => "sequentially",
                                            upgrade_policy                => "simultaneously",
                                            distribution_dependent_group  => 'distgroup1',
                                            upgrade_dependent_group       => 'distgroup2',
                                            distribution_time             => '2020-12-22T11:22:33Z',
                                            upgrade_time                  => '2021-12-22T11:22:33Z',
                                            members                       => [$member1],
                                            );

my $response = $session->add($sgu)
unless($response) {
     die("Add upgrade group failed: ",
           session->status_code() . ":" . session->status_detail());
}
print "Upgrade group created successfully\n";
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Upgrade Group object:

 name          - Optional. Group name in string format.
 comment       - Optional. Comment in string format.
```

Example

```
my @retrieved_objs = $session->get(
    object      => "Infoblox::Grid::UpgradeGroup",
    name        => "testgroup" );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment.
$upgradegroup->comment("This is a modified comment");
# Submit modification
my $response = $session->modify( $upgradegroup );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, use `get()` or `search()` to retrieve the specific object first, and then submit this object for removal.

Example

```
# Get the group object
my @retrieved_objs = $session->get(
    object      => "Infoblox::Grid::UpgradeGroup",
    name        => "testgroup" );
# Find the desired object from the retrieved list.
my $desired_group = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_group );
```

Infoblox::Session->search( )

Use this method to search for Upgrade Group objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific Upgrade Group object:
```

```
 name          - Optional. Group name in string format (regular expression).
 comment       - Optional. Comment in string format (regular expression).
```

Example

```
# Search for all Upgrade Group objects that start with "test"
my @retrieved_objs = $session->search(
    object      => "Infoblox::Grid::UpgradeGroup",
    name        => "test.*",
);
```

Infoblox::Grid::UpgradeSchedule->groups( )

Use this function to specify the groups that belong to this upgrade schedule. See Infoblox::Grid::UpgradeSchedule->groups() for parameters and return values.

Infoblox::Grid::DistributionSchedule->groups( )

Use this function to specify the groups that belong to this distribution schedule. See Infoblox::Grid::DistributionSchedule->groups() for parameters and return values.

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of an upgrade group object.

comment( )

Use this method to set or retrieve the comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Comment in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $upgradegroup->comment();
#Modify comment
$upgradegroup->comment("descriptive comment");
```

distribution_policy( )

Use this method to set or retrieve the distribution policy of this Upgrade Group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The distribution policy. Valid values are "sequentially" and "simultaneously". The default is "simultaneously".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get distribution_policy
my $distribution_policy = $upgradegroup->distribution_policy();
#Modify distribution_policy
$upgradegroup->distribution_policy("sequentially");
```

distribution_dependent_group( )

Use this method to set or retrieve the distribution dependent group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the distribution dependent group.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get distribution_dependent_group
my $distribution_dependent_group = $upgradegroup->distribution_dependent_group();
#Modify distribution_dependent_group
$upgradegroup->distribution_dependent_group("group2");
```

distribution_time( )

Use this method to set or retrieve the distribution time.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note this member is inserted only if the Upgrade Group is submitted for modification as part of an Infoblox::Grid::DistributionSchedule update, this member will not be changed if the Upgrade Group is submitted for modification as a stand-alone object.

Note that if distribution_dependent_group is set, distribution_time will be ignored.

Parameter

The start time of the distribution in ISO 8601 extended format (e.g. 2008-10-21T10:56:00Z or 2008-10-21T10:56:00.001Z).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get distribution_time
my $distribution_time = $upgradegroup->distribution_time();
#Modify distribution_time
$upgradegroup->distribution_time("2008-10-21T10:56:00.001Z");
```

members( )

Use this method to set or retrieve the members of this upgrade group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Array reference that contains Infoblox::Grid::UpgradeGroup::Member object. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get members
my $members = $upgradegroup->members();
#Modify members
$upgradegroup->members([$ug1, $ug2, $ug3]);
```

name( )

Use this method to set or retrieve the name of this upgrade group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $upgradegroup->name();
#Modify name
$upgradegroup->name("group2");
```

time_zone( )

Use this method to retrieve the time_zone for this upgrade group.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get time_zone
my $time_zone = $upgradegroup->time_zone();
```

upgrade_dependent_group( )

Use this method to set or retrieve the upgrade dependent group.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the upgrade dependent group.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get upgrade_dependent_group
my $upgrade_dependent_group = $upgradegroup->upgrade_dependent_group();
#Modify upgrade_dependent_group
$upgradegroup->upgrade_dependent_group("group2");
```

upgrade_policy( )

Use this method to set or retrieve the upgrade_policy.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The upgrade policy. Valid values are "sequentially" and "simultaneously". The default is "simultaneously".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get upgrade_policy
my $upgrade_policy = $upgradegroup->upgrade_policy();
#Modify upgrade_policy
$upgradegroup->upgrade_policy("sequentially");
```

upgrade_time( )

Use this method to set or retrieve the upgrade time.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note this member is inserted only if the Upgrade Group is submitted for modification as part of an Infoblox::Grid::UpgradeSchedule update, this member will not be changed if the Upgrade Group is submitted for modification as a stand-alone object.

Parameter

The start time of the upgrade in ISO 8601 extended format (e.g. 2008-10-21T10:56:00Z or 2008-10-21T10:56:00.001Z).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get upgrade_time
my $upgrade_time = $upgradegroup->upgrade_time();
#Modify upgrade_time
$upgradegroup->upgrade_time("2008-10-21T10:56:00.001Z");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to an Upgrade Group insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "127.0.0.1", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
               );

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a few Upgrade Group objects

```
my $group1 = Infoblox::Grid::UpgradeGroup->new(
                                          name => "group1",
                                         );

unless ($group1) {
       die("Construct group object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Group object created successfully\n";

my $group2 = Infoblox::Grid::UpgradeGroup->new(
                                          name => "group2",
                                         );

$session->add($group1)
       or die("Add Upgrade Group object failed: ",
                       $session->status_code() . ":" . $session->status_detail());
print "Upgrade Group object added to server successfully\n";

unless ($group2) {
       die("Construct group object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Group object created successfully\n";

$session->add($group2)
```

```
        or die("Add Upgrade Group object failed: ",
                        $session->status_code() . ":" . $session->status_detail());
print "Upgrade Group object added to server successfully\n";

# Note that this has to be a valid Grid member name
my $member = Infoblox::Grid::UpgradeGroup::Member->new(
                                                        member      => 'grid_member.com',
                                                       );

my $group3 = Infoblox::Grid::UpgradeGroup->new(
                                               name                          => "group3",
                                               comment                       => "descriptive comment",

NAME

Infoblox::Grid::UpgradeGroup::Member - Upgrade Group Member object

DESCRIPTION

This object is used to represent Upgrade Group Grid members.

CONSTRUCTOR

```
my $member = Infoblox::Grid::UpgradeGroup::Member->new(
    member          => $string, # Required, name of the member
);
```

MODULE METHODS

The following functions are available to apply to an Upgrade Group Member object.

Infoblox::Grid::UpgradeGroup->members( )

Use this function to specify the members that belong to this upgrade group. See Infoblox::Grid::UpgradeGroup->members() for parameters and return values.

Example

```
my $member1 = Infoblox::Grid::UpgradeGroup::Member->new(
                                                        member => 'hostname.com',
                                                       );
unless($member1) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create the upgrade group object with this member
my $sgu = Infoblox::Grid::UpgradeGroup->new(
                                            name                          => "groupname1",
                                            comment                       => "group name 1 comment",
                                            distribution_policy           => "sequentially",
                                            upgrade_policy                => "simultaneously",
                                            distribution_dependent_group  => 'distgroup1',
                                            upgrade_dependent_group       => 'distgroup2',
                                            distribution_time             => '2020-12-22T11:22:33Z',
                                            upgrade_time                  => '2021-12-22T11:22:33Z',
                                            members                       => [$member1],
                                            );

my $response = $session->add($sgu)
unless($response) {
     die("Add upgrade group failed: ",
           session->status_code() . ":" . session->status_detail());
}
print "Upgrade group created successfully\n";
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of an Upgrade Group Member object.

member( )

Use this method to set or retrieve the name of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the grid member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member
my $member = $member->member();
#Modify member
$member->member("192.168.1.3");
```

time_zone( )

Use this method to retrieve the time zone of the member.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get time_zone
my $time_zone = $member->time_zone();
```

NAME

Infoblox::Grid::UpgradeSchedule - Information about the Grid's upgrade schedule.

DESCRIPTION

The Upgrade Schedule object is used to set and view the upgrade schedule of an Infoblox Grid.

CONSTRUCTOR

The Infoblox::Grid::UpgradeSchedule object is automatically generated. It does not require manual construction.

SESSION METHODS

This section describes all the methods in an Infoblox::Session that can be applied to an Upgrade Schedule object.

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my $schedule = $session->get(object => "Infoblox::Grid::UpgradeSchedule");
```

Infoblox::Session->modify( )

Use this method to modify objects in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Submit modification
my $response = $session->modify( $schedule );
```

METHODS

This section describes all the methods that can be used to set or retrieve the attribute values of an Upgrade Schedule object.

active( )

Use this method to set or retrieve the "active" flag.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the active flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get active
my $active = $schedule->active();
#Modify active
$schedule->active("true");
```

groups( )

Use this method to set or retrieve the list of groups affected by this upgrade schedule.

Parameter

Array reference that contains each Infoblox::Grid::UpgradeGroup object.

Note that the members of this list must have their upgrade_time member set in order for the modification to succeed. This means that it is possible to retrieve an upgrade schedule but not be allowed to modify it without setting the upgrade_time values for the groups.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Get the group list
my $grouplist = $schedule->groups();
#Modify it
$grid->groups([$ug1, $ug2, $ug3 ]);
```

start_time( )

Use this method to set or retrieve the start time of the upgrade.

Parameter

The start time of the upgrade in ISO 8601 extended format (e.g. 2008-10-21T10:56:00Z or 2008-10-21T10:56:00.001Z).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get start_time
my $start_time = $schedule->start_time();
#Modify start_time
$schedule->start_time("2020-12-21T11:22:33Z");
```

time_zone( )

Use this method to set or retrieve the time zone of the upgrade schedule.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The UTC string that represents the time zone. For example "(UTC - 6:00) Central Time (US and Canada)". Default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get time_zone
my $time_zone = $schedule->time_zone();
#Modify time_zone
$schedule->time_zone("(UTC - 6:00) Central Time (US and Canada)");
```

NAME

Infoblox::Grid::UpgradeStatus - Information about the Grid's upgrade status.

DESCRIPTION

The Upgrade Status object is used to view the upgrade status of an Infoblox Grid.

CONSTRUCTOR

The Infoblox::Grid::UpgradeStatus object is automatically generated. It does not require manual construction.

SESSION METHODS

This section describes all the methods in an Infoblox::Session that can be applied to an Upgrade Status object.

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Example

```
my @statistics = $session->get(object => "Infoblox::Grid::UpgradeStatus");
```

METHODS

This section describes all the methods that can be used to retrieve the attribute values of an Upgrade Status object.

allow_distribution( )

Use this method to determine if distribution is allowed for the Grid.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get allow_distribution
my $allow_distribution = $upgstatus->allow_distribution();
```

allow_upgrade( )

Use this method to determine if upgrade is allowed for the Grid.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get allow_upgrade
my $allow_upgrade = $upgstatus->allow_upgrade();
```

allow_upgrade_cancel( )

Use this method to determine if the Grid is allowed to cancel an upgrade.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get allow_upgrade_cancel
my $allow_upgrade_cancel = $upgstatus->allow_upgrade_cancel();
```

allow_upgrade_pause( )

Use this method to determine if the Grid is allowed to pause an upgrade.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get allow_upgrade_pause
my $allow_upgrade_pause = $upgstatus->allow_upgrade_pause();
```

allow_upgrade_resume( )

Use this method to determine if the Grid is allowed to resume an upgrade.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get allow_upgrade_resume
my $allow_upgrade_resume = $upgstatus->allow_upgrade_resume();
```

allow_upgrade_scheduling( )

Use this method to determine if the Grid is allowed to schedule an upgrade.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get allow_upgrade_scheduling
my $allow_upgrade_scheduling = $upgstatus->allow_upgrade_scheduling();
```

allow_upgrade_test( )

Use this method to determine if the Grid is allowed to test an upgrade.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get allow_upgrade_test
my $allow_upgrade_test = $upgstatus->allow_upgrade_test();
```

allow_upload( )

Use this method to determine if the Grid is allowed to upload a build.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get allow_upload
my $allow_upload = $upgstatus->allow_upload();
```

distribution_schedule_active( )

Use this method to determine if the distribution schedule is active for the Grid.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get distribution_schedule_active
my $distribution_schedule_active = $upgstatus->distribution_schedule_active();
```

grid_state( )

Use this method to retrieve the Grid state.

Parameter

none

Returns

The method returns the attribute value. Valid values are

```
"NONE", "DISTRIBUTING_COMPLETE", "DISTRIBUTING_ENDED", "DISTRIBUTING_PAUSED",
"DISTRIBUTING", "DISTRIBUTING_FAILED", "DEFAULT", "UPGRADING", "REVERT",
"TEST_UPGRADING", "UPGRADING_COMPLETE", "UPGRADING_FAILED",
"REVERTING_COMPLETE", "DOWNGRADING_COMPLETE", "UPLOADED",
```

```
"DOWNGRADING_FAILED", "UPGRADING_PAUSED"
```

Example

```
#Get grid_state
my $grid_state = $upgstatus->grid_state();
```

group_state( )

Use this method to retrieve the group state.

Parameter

none

Returns

The method returns the attribute value. Valid values are

```
"GROUP_NONE", "GROUP_DISTRIBUTING_WAITING", "GROUP_DISTRIBUTING",
"GROUP_DISTRIBUTING_COMPLETE", "GROUP_UPGRADING_WAITING", "GROUP_UPGRADING",
"GROUP_UPGRADING_COMPLETE", "GROUP_DISTRIBUTING_FAILED"
```

Example

```
#Get group_state
my $group_state = $upgstatus->group_state();
```

message( )

Use this method to retrieve the grid message.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get message
my $message = $upgstatus->message();
```

status_time( )

Use this method to retrieve the status time.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get status_time
my $status_time = $upgstatus->status_time();
```

upgrade_schedule_active( )

Use this method to determine if the upgrade schedule is active.

Parameter

none

Returns

The method returns the attribute value. Valid values are "true" or "false".

Example

```
#Get upgrade_schedule_active
my $upgrade_schedule_active = $upgstatus->upgrade_schedule_active();
```

upgrade_state( )

Use this method to retrieve the upgrade state of the Grid.

Parameter

none

Returns

The method returns the attribute value. Valid values are "NONE" or "PROGRESSING".

Example

```
#Get upgrade_state
my $upgrade_state = $upgstatus->upgrade_state();
```

upgrade_test_status( )

Use this method to retrieve the upgrade test status of the Grid.

Parameter

none

Returns

The method returns the attribute value. Valid values are "NONE", "PROGRESSING", "COMPLETED" or "FAILED".

Example

```
#Get upgrade_test_status
my $upgrade_test_status = $upgstatus->upgrade_test_status();
```

);
```

SESSION METHODS

This section describes all the methods in Infoblox::Session that you can apply to a vDiscovery task object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $task = Infoblox::Grid::VDiscoveryTask->new(
   name             => "taskname",
   comment          => "descriptive comment",
);
# Submit for addition
my $response = $session->add( $task );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific grid object:

  name                  - Optional. A name of the cloud discovery task in string format.
  member                - Optional. A host name of the member the cloud discovery task is assigned toin string
format.
  fqdn_or_ip            - Optional. A FQDN or IP of the cloud management platform in string format.
  protocol              - Optional. A connection protocol used for connecting to the cloud management platform
in string format.
  port                  - Optional. A connection port used for connecting to the cloud management platform in
string format.
  public_network_view   - Optional. A network view name for public IPs in string format.
  private_network_view  - Optional. A network view name for private IPs in string format.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  comment               - Optional. A comment in string format.
```

Example

```
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::VDiscoveryTask",
    name   => "taskname",
);
```

Infoblox::Session->remove( )

Use this method to submit an object for removal from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the object, and then submit this object for removal.

Example

```
# Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::VDiscoveryTask",
    name   => "taskname",
);

# Find the desired object on the retrieved list.
my $desired_task = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_task );
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
 Apply the following attributes to search for a task object:

  name                  - Optional. A name of the cloud discovery task in string format.
  member                - Optional. A host name of the member the cloud discovery task is assigned toin string
format.
  fqdn_or_ip            - Optional. A FQDN or IP of the cloud management platform in string format.
  protocol              - Optional. A connection protocol used for connecting to the cloud management platform
in string format.
  port                  - Optional. A connection port used for connecting to the cloud management platform in
string format.
  public_network_view   - Optional. A network view name for public IPs in string format.
  private_network_view  - Optional. A network view name for private IPs in string format.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  comment               - Optional. A comment in string format.
```

For more information about searching extensible attributes, see Infoblox::MasterGrid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all map objects objects that have "sub" in their name
my @retrieved_objs = $session->search(
    object => "Infoblox::Grid::VDiscoveryTask",
    name   => "sub.*",
);
```

Infoblox::Session->modify( )

Use this method to modify objects in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the name
$task->comment("some other comment");
# Submit modification
my $response = $session->modify( $task );
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the discovered data object.

name( )

Use this method to set or retrieve the name of the vDiscovery task.

Parameter

The the name of the vDiscovery task in string format. The name uniquely identify a vDiscovery task.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->name();
# Modify attribute value
$object->name('name');
```

member( )

Use this method to set or retrieve the host name of the member to which the vDiscovery task is assigned.

Parameter

The host name of the member (in string format) to which the vDiscovery task is assigned.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->member();
# Modify attribute value
$object->member('member');
```

scheduled_run( )

Use this method to set or retrieve the schedule setting for the vDiscovery task.

Parameter

Valid value is an Infoblox::Grid::ScheduleSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->scheduled_run();
# Modify attribute value
$object->scheduled_run($schedule);
```

state( )

Use this method to retrieve the current state of the vDiscovery task. This is a read-only attribute.

Parameter

None

Returns

Valid values are 'IDLE' (waiting), 'READY' (ready run), 'RUNNING' (the task is running), 'COMPLETE' (successfully completes discovery), 'COLLECTION_COMPLETE' (successfully completed collection), 'WARNING' (discovery completed with errors), 'ERROR' (fails to discover), 'CANCEL_PENDING' (cancelling equals pending). The default value is 'IDLE'.

Example

```
# Get attribute value
my $value = $object->state();
```

enabled( )

Use this method to set or retrieve the flag used to control whether the vDiscovery task is running or not.

Parameter

Specify "true" to enable port scanning or "false" to disable it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->enabled();
# Modify attribute value
$object->enabled('true');
```

comment( )

Use this method to set or retrieve the comment of the task.

Parameter

The comment of the task in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->comment();
# Modify attribute value
$object->comment('comment');
```

public_network_view_mapping_policy( )

Use this method to set or retrieve the mapping policy for the network view for public IPs in discovered data.

Parameter

Map the policy using a specified network view ('DIRECT') or map the policy using the network view resolved from the tenant ID ('AUTO_CREATE').

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->public_network_view_mapping_policy();
# Modify attribute value
$object->public_network_view_mapping_policy('DIRECT');
```

public_network_view( )

Use this method to set or retrieve the name of the network view for public IPs.

Parameter

The name of the network view for public IPs in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->public_network_view();
# Modify attribute value
$object->public_network_view('public_network_view');
```

private_network_view_mapping_policy( )

Use this method to set or retrieve the mapping policy for the network view for private IPs in discovered data.

Parameter

Map the policy using a specified network view ('DIRECT') or map the policy using the network view resolved from the tenant ID ('AUTO_CREATE').

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->private_network_view_mapping_policy();
# Modify attribute value
$object->private_network_view_mapping_policy('DIRECT');
```

private_network_view( )

Use this method to set or retrieve the name of the network view for private IPs.

Parameter

The name of the network view for private IPs in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->private_network_view();
# Modify attribute value
$object->private_network_view('private_network_view');
```

driver_type( )

Use this method to set or retrieve the type of discovery driver that applies to the vDiscovery task.

Parameter

The type of discovery driver that applies to the vDiscovery task in string format. Valid value is 'AWS' (Amazon Web Service), 'AZURE'(Microsoft Azure), OPENSTACK' (OpenStack) or 'VMWARE' (VMWare).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->driver_type();
# Modify attribute value
$object->driver_type('VMWARE');
```

fqdn_or_ip( )

Use this method to set or retrieve the FQDN or IP of the Cloud Management Platform.

Parameter

The FQDN or IP of the Cloud Management Platform in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->fqdn_or_ip();
# Modify attribute value
$object->fqdn_or_ip('fqdn_or_ip');
```

protocol( )

Use this method to set or retrieve the connection protocol used for connecting to the Cloud Management Platform.

Parameter

The connection protocol used for connecting to the Cloud Management Platform in string format. Valid value is 'HTTP' or 'HTTPS'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->protocol();
# Modify attribute value
$object->protocol('HTTP');
```

port( )

Use this method to set or retrieve the connection port used for connecting to the Cloud Management Platform.

Parameter

The connection port used for connecting to the Cloud Management Platform in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->port();
# Modify attribute value
$object->port('port');
```

username( )

Use this method to set or retrieve the username used for connecting to the Cloud Management Platform. This attribute is mandatory if credentials_type is "DIRECT".

Parameter

The username used for connecting to the Cloud Management Platform in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->username();
# Modify attribute value
$object->username('username');
```

password( )

Use this method to set the password used for connecting to the Cloud Management Platform. This is a write-only attribute. This attribute is mandatory if credentials_type is "DIRECT".

Parameter

The password used for connecting to the Cloud Management Platform in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
# Modify attribute value
$object->password('password');
```

state_msg( )

Use this method to retrieve the state message of the complete discovery process. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->state_msg();
```

last_run_time( )

Use this method to set or retrieve the timestamp of the last vDiscovery task.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->last_run_time();
```

update_metadata( )

Use this method to control whether to update the metadata as a result of the vDiscovery or not.

Parameter

Specify "true" to update the metadata as a result of the vDiscovery or "false" to not update it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->update_metadata();
# Modify attribute value
$object->update_metadata('true');
```

merge_data( )

Use this method to control whether to replace the old data with the new one or not.

Parameter

Specify "true" to replace the old data with the new one or "false" to not replace it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->merge_data();
# Modify attribute value
$object->merge_data('true');
```

auto_consolidate_managed_tenant( )

Use this method to control whether to replace managed tenant with discovered tenant data.

Parameter

Specify "true" to replace managed tenant with discovered tenant data or "false" to not replace it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->auto_consolidate_managed_tenant();
# Modify attribute value
$object->auto_consolidate_managed_tenant('true');
```

auto_consolidate_managed_vm( )

Use this method to control whether to replace managed virtual machine with discovered virtual machine data.

Parameter

Specify "true" to replace managed virtual machine with discovered virtual machine data or "false" to not replace it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->auto_consolidate_managed_vm();
# Modify attribute value
$object->auto_consolidate_managed_vm('true');
```

auto_consolidate_cloud_ea( )

Use this method to control whether to insert or update cloud EAs with discovered data.

Parameter

Specify "true" to insert or update cloud EAs with discovered data or "false" to not do it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->auto_consolidate_cloud_ea();
# Modify attribute value
$object->auto_consolidate_cloud_ea('true');
```

auto_create_dns_record( )

Use this method to set or retrieve the flag that indicates whether the automatic creation and update of DNS records using discovered data is enabled or disabled.

Parameter

Specify 'true' to enable automatic creation and update of DNS records with discovered data or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->auto_create_dns_record();
# Modify attribute value
$object->auto_create_dns_record('false');
```

auto_create_dns_record_type( )

Use this method to set or retrieve the type of record to create if the auto-creation of DNS records is enabled.

Parameter

The type of record to create if the auto-creation of DNS records is enabled. Valid values are 'HOST_RECORD' (host record) or 'A_PTR_RECORD' (A (AAAA) record and ptr record combination). Default is 'HOST_RECORD'.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->auto_create_dns_record_type();
# Modify attribute value
$object->auto_create_dns_record_type('HOST_RECORD');
```

auto_create_dns_hostname_template( )

Use this method to set or retrieve the template string used to generate host names.

Parameter

Template string used to generate host names.

Note that using double quotes may lead to interpolation of variables. Instead, use single quotes or encapsulated '$' characters.

Parameter

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->auto_create_dns_hostname_template();
# Modify attribute value
$object->auto_create_dns_hostname_template('${vm_name}.test.com');
```

vdiscovery_control( )

Use this method to start a task or to cancel a task.

Parameter

action - Action being requested in string format. Support starting ('START') an IDLE vDiscovery task or cancelling ('CANCEL') a RUNNING vDiscovery task. Valid value is 'START' or 'CANCEL'.

Returns

The method returns "true" if the action has been performed successfully , and returns "false" when the actions fails.

Example

```
my $res = $cdiscovery->vdiscovery_control('action' => 'START');
```

credentials_type( )

Use this method to set or retrieve the type of credentials used for connecting to the Cloud Management Platform.

Parameter

The credentials type used for connecting to the Cloud Management Platform in string format. Valid values are 'DIRECT' or 'INDIRECT'. Default is 'DIRECT'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->credentials_type();
# Modify attribute value
$object->credentials_type('INDIRECT');
```

allow_unsecured_connection( )

Use this method to set or retrieve the flag that indicates whether the remote SSL certificate is validated or not. If set to 'true', the certificate will not be validated.

Parameter

Specify 'true' to disable the validation of the remote SSL certificate or 'false' to enable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->allow_unsecured_connection();
# Modify attribute value
$object->allow_unsecured_connection('false');
```

update_dns_view_public_ip( )

Use this method to set or retrieve the flag that indicates whether the appliance should use a specific DNS view for public IPs.

Parameter

Specify 'true' to use a specific DNS view for public IPs or 'false' to not use.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->update_dns_view_public_ip();
# Modify attribute value
$object->update_dns_view_public_ip('false');
```

dns_view_public_ip( )

The DNS view name for public IPs. If you configure this option, you must also set update_dns_view_public_ip to true. Otherwise, set update_dns_view_public_ip to false.

Parameter

The valid value is DNS view name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->dns_view_public_ip();
# Modify attribute value
$object->dns_view_public_ip('public_dns_view');
```

update_dns_view_private_ip( )

Use this method to set or retrieve the flag that indicates whether the appliance should use a specific DNS view for private IPs.

Parameter

Specify 'true' to use a specific DNS view for private IPs or 'false' to not use.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->update_dns_view_private_ip();
# Modify attribute value
$object->update_dns_view_private_ip('false');
```

dns_view_private_ip( )

The DNS view name for private IPs. If you configure this option, you must also set update_dns_view_private_ip to true. Otherwise, set update_dns_view_private_ip to false.

Parameter

The valid value is DNS view name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->dns_view_private_ip();
# Modify attribute value
$object->dns_view_private_ip('private_dns_view');
```

identity_version( )

Use this method to set or retrieve the OpenStack identity service version.

Parameter

The OpenStack identity service version in string format. Valid value is 'KEYSTONE_V2', 'KEYSTONE_V3'. Default value is 'KEYSTONE_V2'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->identity_version();
# Modify attribute value
$object->identity_version('KEYSTONE_V3');
```

domain_name( )

Use this method to set or retrieve the name of the domain to use with Keystone v3.

Parameter

The name of the domain to use with Keystone v3. Must be set if 'identity_version' set to 'KEYSTONE_V3'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $object->domain_name();
# Modify attribute value
$object->domain_name('Default');
```

NAME

Infoblox::Grid::X509Certificate - An X509Certificate object.

DESCRIPTION

An X509Certificate object.

CONSTRUCTOR

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to an X509Certificate object.

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
 Apply the following attributes to get for an X509Certificate object:

  serial              - Optional. The certificate serial number in hex format.
  issuer              - Optional. The name of the issuer.
  distinguished_name  - Optional. The certificate subject name.
  valid_not_after     - Optional. String that contains a desired value of the certificate expiration
date in ISO 8601 format.
  valid_not_before    - Optional. String that contains a desired value of the certificate start date
in ISO 8601 format.
```

Example

```
 # Retrieve X509Certificate objects with specify certificate subject name
 my @retrieved_objs = $session->get(
        object            => 'Infoblox::Grid::X509Certificate',
        distinguished_name => 'CN="10.34.1.106",OU="Engineering",O="Infoblox Inc",L="Santa
Clara",ST="California",C="US"',
 );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
 # Get X509Certificate object
 my @retrieved_objs = $session->get(
        object            => 'Infoblox::Grid::X509Certificate',
        distinguished_name => 'CN="10.34.1.106",OU="Engineering",O="Infoblox Inc",L="Santa
```

```
Clara",ST="California",C="US"',
 );

 # Find the desired object from the retrieved list
 my $x509cert = $retrieved_objs[0];

 # Submit for removal
 my $response = $session->remove( $x509cert );
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
 Apply the following attributes to search for an X509Certificate object:

  serial              - Optional. The certificate serial number in hex format.
  issuer              - Optional. The name of the issuer.
  distinguished_name  - Optional. The certificate subject name.
  valid_not_after     - Optional. String that contains a desired value of the certificate expiration
date in ISO 8601 format.
  valid_not_before    - Optional. String that contains a desired value of the certificate start date
in ISO 8601 format.
```

Example

```
 # Retrieve X509Certificate objects with specify certificate subject name
 my @retrieved_objs = $session->search(
        object             => 'Infoblox::Grid::X509Certificate',
        distinguished_name => 'CN="10.34.1.106",OU="Engineering",O="Infoblox Inc",L="Santa
Clara",ST="California",C="US"',
 );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a X509Certificate object.

issuer( )

Use this method to retrieve the issuer subject name. This method does not support any argument because the attribute is read-only and is set by the server.

Parameter

None

Returns

The method returns the attribute value.

Example

```
 # Get attribute value
 my $issuer = $x509cert->issuer();
```

serial( )

Use this method to retrieve the certificate serial number in hex format. This method does not support any argument because the attribute is read-only and is set by the server.

Parameter

None

Returns

The method returns the attribute value.

Example

```
 # Get attribute value
 my $serial = $x509cert->serial();
```

distinguished_name( )

Use this method to retrieve the certificate subject name. This method does not support any argument because the attribute is read-only and is set by the server.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $distinguished_name = $x509cert->distinguished_name();
```

valid_not_before( )

Use this method to retrieve the date before the certificate becomes invalid in ISO 8601 format. This method does not support any argument because the attribute is read-only and is set by the server.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $valid_not_before = $x509cert->valid_not_before();
```

valid_not_after( )

Use this method to retrieve the date after the certificate becomes invalid in ISO 8601 format. This method does not support any argument because the attribute is read-only and is set by the server.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $valid_not_after = $x509cert->valid_not_after();
```

NAME

Infoblox::IFMap::CACertificate - IF-MAP CA Certificate object.

DESCRIPTION

You can configure the Infoblox appliance as a metadata access point (MAP) and implement the IF-MAP protocol defined by the Trusted Computing Group (TCG, www.trustedcomputinggroup.com). This module provides an interface for configuring CA certificates that the IF-MAP server uses to authenticate IF-MAP clients.

CONSTRUCTOR

```
my $ca_cert=Infoblox::IFMap::CACertificate->new(
    certificate      => $string, #Required
);
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to an IF-MAP CA Certificate object.

Infoblox::Session->add( )

Use this method to add a new CA certificate for the IF-MAP server. See Infoblox::Session->add( ) for parameters and return values.

Example

```
# Read the certificate contents from the file
open CERTFILE "<cert.pem" or die "Unable to open certificate file";
my $pem_cert = join('', <CERTFILE>);

# Create a new CA certificate object
my $cacert = Infoblox::IFMap::CACertificate->new(
certificate => $pem_cert
);

# Add the CA certificate
my $response = $session->add( $cacert );
```

Infoblox::Session->get( )

Use this method to retrieve the CA certificates configured for the IF-MAP server. See Infoblox::Session->get( ) for parameters and return values.

Key References

Apply the following attributes to get a specific IF-MAP CA certificate object:

```
subject                - Optional. String that contains a certificate subject.
issuer                 - Optional. String that contains a certificate issuer.
```

```
 valid_not_after        - Optional. String that contains a desired value of the certificate
expiration date in ISO 8601 format.
 valid_not_before       - Optional. String that contains a desired value of the certificate start
date in ISO 8601 format.
```

Example

```
# Retrieve CA certificate with the subject = "/CN=verisign.com/OU=Verisign"
my @retrieved_objs = $session->get(
object => "Infoblox::IFMap::CACertificate",
subject => "/CN=verisign.com/OU=Verisign"
);
```

Infoblox::Session->remove( )

Use this method to remove a CA certificate.

Examples

```
# Get the CA certificate
my @retrieved_objs = $session->get(
object => "Infoblox::IFMap::CACertificate",
subject   => "/CN=verisign.com/OU=Verisign"
);

# Find the desired object from the retrieved list.
my $desired_cert = $retrieved_objs[0];

# Submit for removal
my $response = $session->remove( $desired_cert );
```

Infoblox::Session->search( )

Use this method to search for the CA certificates configured for the IF-MAP server. You can specify the following attributes in a search: subject, issuer, valid_not_before, and valid_not_after.

Key References

Apply the following attributes to search for a specific IF-MAP CA certificate object:

```
 subject                - Optional. Regex for the certificate subject.
 issuer                 - Optional. Regex for the certificate issuer.
 valid_not_after        - Optional. String that contains the desired certificate expiration date in
ISO 8601 format. This method supports searching with limit parameters  (see below).
 valid_not_before       - Optional. String that contains the desired certificate start date in ISO
8601 format. This method supports searching with limit parameters  (see below).
```

See Infoblox::Session/search with limit parameters for more information on this functionality.

Examples

```
# Search for IF-MAP CA certificates issued by Verisign
# and with valid not before time in 2010
my @retrieved_objs = $session->search(
object => "Infoblox::IFMap::CACertificate",
issuer => ".*verisign.*",
valid_not_before => ">=< 2010-01-01T00:00:00Z,2011-01-01T00:00:00Z",
);
```

METHODS

certificate( )

Use this method to retrieve or set the value of the certificate attribute. If no argument is passed, the method returns the current attribute value. The value must be a single certificate in PEM format.

Parameter

The valid value is a string that contains the certificate in PEM format. This is a required attribute.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Examples

```
# Get certificate
```

```
my $pem_cert = $cert_object->certificate( );

# Set certificate
open CERTFILE "<cert.pem" or die "Unable to open certificate file";
my $pem_cert = join('', <CERTFILE>);
$cert_object->certificate( $pem_cert );
```

subject( )

Use this method to retrieve the value of the subject attribute. This method does not support any argument because the attribute is read-only and is set by the server. It has a value only when it reads an existing certificate from the Infoblox::IFMap::CACertificate object retrieved from the appliance.

Parameter

N/A.

Returns

The method returns the attribute value.

This is a read-only attribute. If you specify a parameter, the method returns an error.

Examples

```
# Get subject
my $subject = $certificate->subject( );
```

issuer( )

Use this method to retrieve the value of the =issuer= attribute. This method does not support any argument because the attribute is read-only and is set by the server. It has a value only when it reads an existing certificate from the =Infoblox::IFMap::CACertificate= object.

Parameter

N/A.

Returns

The method returns the attribute value.

This is a read-only attribute. If you specify a parameter, the method returns an error.

Examples

```
# Get subject
my $issuer = $certificate->issuer( );
```

valid_not_before( )

Use this method to retrieve the value of the valid_not_before attribute. This method does not support any argument because the attribute is read-only and is set by the server. It has a value only when it reads an existing certificate from the Infoblox::IFMap::CACertificate object. The returned value is the date before the certificate becomes invalid in ISO 8601 format.

Parameter

N/A.

Returns

The method returns the attribute value.

This is a read-only attribute. If you specify a parameter, the method returns an error.

Examples

```
# Get valid_not_before attribute
my $valid_not_before = $certificate->valid_not_before( );
```

valid_not_after( )

Use this method to retrieve the value of the valid_not_after attribute. This method does not support any argument because it is read-only and is set by the server. It has a value only when it reads an existing certificate from the Infoblox::IFMap::CACertificate object. The returned value is the date after the certificate becomes invalid in the ISO 8601 format.

Parameter

N/A.

Returns

The method returns the attribute value.

This is a read-only attribute. If you specify a parameter, the method returns an error.

Examples

```
# Get operation
my $valid_not_after = $certificate->valid_not_after( );
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search and remove. This sample also includes error handling for the operations.

#Preparations

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;
#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code( ) . ":" . Infoblox::status_detail( ));
}
print "Session created successfully\n";

#Get a certificate from the external file
local *CERTFILE;
open CERTFILE, "<API_unit_test_sample_code/ca_cert.pem" or die "Unable to open certificate file";
my $pem_cert = join('', <CERTFILE>);
close(CERTFILE);
```

#Create CA certificate object

```
my $ca_certificate= Infoblox::IFMap::CACertificate->new(
                                                          certificate => $pem_cert
                                                        );
unless($ca_certificate) {
       die("Construct CA certificate object failed: ",
               Infoblox::status_code( ) . ":" . Infoblox::status_detail( ));
}
print "IFMap CA Certificate object created successfully\n";
```

#Add the CA Certificate object to the Infoblox appliance through a session

```
$session->add($ca_certificate)
    or die("Add IFMap CA certificate object failed: ",
                        $session->status_code( ) . ":" . $session->status_detail( ));
print "IFMap CA Certificate object added to server successfully\n";

#Get the IFMap CA Certificate object using subject attribute
my @retrieved_objs=$session->get(
                                  object => "Infoblox::IFMap::CACertificate",
                                  subject => 'CN="Test CA 2",OU="Engineering",O="Infoblox",L="Santa
Clara",ST="CA",C="US"'
                                );
my $object = $retrieved_objs[0];
unless($object){
    die("Get IFMap CA Certificate object failed: ",
                $session->status_code( ) . ":" . $session->status_detail( ));
}
print "Get IFMap CA Certificate object found at least 1 matching entry\n";
```

#Search for IFMap CA certificate objects

```
my @retrieved_objs=$session->search(
                                  object => "Infoblox::IFMap::CACertificate",
                                  subject => '.*Engineering.*',
```

```
                                    valid_not_before => '>=< 2010-01-01T08:00:00Z,2010-10-01T00:00:00Z'
                                );
 my $object = $retrieved_objs[0];
 unless($object){
     die("Search for IFMap CA Certificate object failed: ",
                 $session->status_code( ) . ":" . $session->status_detail( ));
 }
 print "Searching IFMap CA Certificate object found at least 1 matching entry\n";
```

#Remove IFMap CA Certificate object

```
 #Get IFMap CA Certificate object
 my @retrieved_objs=$session->get(
                                    object => "Infoblox::IFMap::CACertificate",
                                    subject => 'CN="Test CA 2",OU="Engineering",O="Infoblox",L="Santa
Clara",ST="CA",C="US"'
                                );
 my $object = $retrieved_objs[0];
 unless($object){
     die("Get IFMap CA certificate object failed: ",
                 $session->status_code( ) . ":" . $session->status_detail( ));
 }
 print "Get IFMap CA certificate object found at least 1 matching entry\n";

 #submit the object for removal
 $session->remove($object)
     or die("Remove IFMap CA certificate failed: ",
             $session->status_code( ) . ":" . $session->status_detail( ));
 print "IFMap CA certificate object removed successfully \n";
```

NAME

Infoblox::IFMap::Client::Credentials - IF-MAP Credentials object

DESCRIPTION

This object represents the credentials used by an IF-MAP Federation Connector object.

CONSTRUCTOR

```
my $credentials = Infoblox::IFMap::Federation::Connector::Credentials->new(
    authentication => <"basic" | "certificate">,              #Required
    password => <STRING>,                                     #Required if authentication = "basic"
    server_ca_cert => $cacert,                                #Optional
    server_url => <STRING>,                                   #Optional
    username => <STRING>,                                     #Required if authentication = "basic"
);
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of an IF-MAP Credentials object.

authentication( )

Use this method to set or retrieve the value of the authentication attribute.

Parameter

A string that represents the attribute. Valid strings are "basic" or "certificate".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the authentication attribute.

Example

```
# Get authentication
my $authentication = $credentials->authentication( );

# Change it
$credentials->authentication("basic");
```

password( )

Use this method to set the value of the password attribute. This value is not returned by the server when you use the `get()` and `search()` session methods. This password is used for Basic Authentication and is required if authentication is set to "basic". This is a write-only attribute.

Parameter

A string that specifies the password.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
# Set it
$credentials->password("secret");
```

server_ca_cert( )

Use this method to set or retrieve the value of the server_ca_cert attribute. This configures the CA certificate to use for server certificate validation.

Parameter

An Infoblox::IFMap::CACertificate object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute server_ca_cert.

Example

```
# Get server_ca_cert
my $server_ca_cert = $credentials->server_ca_cert( );

# Change it
$credentials->server_ca_cert($ca_cert);
```

server_url( )

Use this method to set or retrieve the value of the server_url attribute. It specifies the URL of the federated IF-MAP service.

Parameter

The URL of the IF-MAP service. For example "https://ifmap.infoblox.com:443/ifmap".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute server_url.

Example

```
# Get server_url
my $server_url = $credentials->server_url( );

# Change it
$credentials->server_url("https://ifmap.infoblox.com:443/ifmap");
```

username( )

Use this method to set or retrieve the value of the username attribute. This username is used for Basic Authentication and is required if authentication is set to "basic". It has to be unique per server, specified by the server_url attribute.

Parameter

A string that represents the attribute.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute username.

Example

```
# Get username
my $username = $credentials->username( );

# Change it
$credentials->username("user1");
```

NAME

Infoblox::IPAM::Address - IPAM address object

DESCRIPTION

The IPAM address object is used to view IPv4 and IPv6 address management information in an Infoblox appliance.

CONSTRUCTOR

The Infoblox::IPAM::Address object is a read-only object and does not require manual construction.

SESSION METHODS

This section describes all the methods in an Infoblox::Session that can be applied to an IPAM address object.

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Note that for IPv4 addresses, both used and unused addresses are returned unless 'status' is specified; but IPv6 addresses will only return used addresses.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key Reference

```
 Apply the following attributes to get the IPAM address object(s). Note that at least one of the
following is required: address, start_addr, end_addr, or network.
```

address - Optional. An IPv4 or IPv6 address. Get IPAM information for this address. All other optional arguments are ignored, except for network_view, if 'address' is present.

network - Optional. The IPv4 or IPv6 network, in CIDR notation (e.g 1.0.0.0/8 or 2000::/64), where the IPAM address is located.

network_view - Optional. The network view in which the network is located. The default is the system-defined default network view.

start_addr - Optional. An IPv4 or IPv6 address. Start address of an IPAM address scope. If the start address is not in the specified network, an error is returned.

end_addr - Optional. An IPv4 or IPv6 address. End address of an IPAM address scope. If the end address is not in the specified network, an error is returned.

status - Optional. The filter type of the IPAM address. Valid values are "used", "unused" and "all". Default value is "all". This argument applies to IPv4 addresses only. When the value is returned ", Unmanaged" or ", Conflict" might be appended to the status member when applicable.

type - Optional. This is exactly the same as the 'status' argument, and is being deprecated in favor of the 'status' argument. This argument applies to IPv4 addresses only.

extattrs - Optional. A hash reference containing extensible attributes.

extensible_attributes - Optional. A hash reference containing extensible attributes.

fingerprint - Optional. DHCP fingerprint description.

discovered_duid - Optional. Discovered DHCPv6 UID.

discovered_name - Optional. Discovered name.

discoverer - Optional. Discoverer name.

first_discovered - Optional. Time of the first discovery.

last_discovered - Optional. Time of the last discovery.

netbios - Optional. Discovered NetBIOS name.

network_component_description - Optional. Discovered network component description.

network_component_ip - Optional. Discovered network component IP address.

network_component_name - Optional. Discovered network component name.

network_component_port_description - Optional. Discovered network component port description.

network_component_port_name - Optional. Discovered network component port name.

network_component_port_number - Optional. Discovered network component port number.

network_component_type - Optional. Discovered network component type.

os - Optional. Discovered OS.

port_duplex - Optional. Discovered port duplex settings.

port_link_status - Optional. Discovered port link status.

port_speed - Optional. Discovered port speed settings.

port_status - Optional. Discovered port status settings.

port_vlan_description - Optional. Discovered port VLAN description.

port_vlan_name - Optional. Discovered port VLAN name.

port_vlan_number - Optional. Discovered port VLAN number.

v_cluster - Optional. Discovered VMware cluster name.

v_datacenter - Optional. Discovered VMware datacenter name.

v_host - Optional. Discovered VMware server name.

v_name - Optional. Discovered VMware host or virtual machine name.

v_netadapter - Optional. Discovered VMware physical network adapter name.

v_switch - Optional. Discovered VMware virtual switch name.

v_type - Optional. Discovered VMware entity type (possible values: "VirtualMachine", "HostSystem", "VirtualCenter").

Example

```
# case 1
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'network'  => '10.0.0.0/8');
```

Since there are no start and end addresses specified, the appliance returns a maximum of 2000 IP addresses, which is the maximum page size of an administrator. If the total number of IP addresses in the network is less than 2000, then it returns all IP addresses.

```
# case 2
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'network'    => '10.0.0.0/8',
                                  'start_addr' => '10.0.0.100');
```

This call returns a maximum of 2000 IPAM addresses starting from 10.0.0.100.

```
# case 3
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'network'    => '10.0.0.0/8',
                                  'start_addr' => '10.0.0.100'
                                  'end_addr'   => '10.0.0.200');
```

This call returns 101 IPAM addresses from 10.0.0.100 to 10.0.0.200.

```
# case 4
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'address'    => '10.0.0.10');
```

This call returns the IPAM address object for 10.0.0.10.

```
# case 5
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'network'  => '10.0.0.0/8',
                                  'start_addr' => '10.0.0.100',
                                  'end_addr'  => '10.0.0.200',
                                  'status'          => 'used' );
```

This call returns used IPAM addresses from 10.0.0.100 to 10.0.0.200. Note that the filter is applied to the specified scope. Therefore, the number of returned objects could be less than 101, if only a few IP addresses are used in this scope.

```
# case 6
my @ipam_objects = $session->get( 'object        => 'Infoblox::IPAM::Address',
                                  'network'      => '10.0.0.0/8',
                                  'network_view' => 'my_network_view');
```

Same as case 1, but this uses the 'my_network_view' network view rather than the system-defined default view.

```
# case 7
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'address'    => '10.0.0.5');
```

```
# case 8
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'network'  => '2000::/64');
```

Since there are no start and end addresses specified, the appliance returns a maximum of 2000 used IP addresses, which is the maximum page size of an administrator. If the total number of IP addresses in the network is less than 2000, then it returns all IP addresses.

```
# case 9
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'network'    => '2000::/64',
                                  'start_addr' => '2000::11');
```

This call returns a maximum of 2000 used IPv6 addresses starting from 2000::11.

```
# case 10
my @ipam_objects = $session->get( 'object'     => 'Infoblox::IPAM::Address',
                                  'network'    => '2000::/64',
                                  'start_addr' => '2000::11',
                                  'end_addr'   => '2000::31');
```

This call returns used IPv6addresses from '2000::11' to '2000::31'.

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Get the object under the same name
my @result_array = $session->get(
      object        => "Infoblox::IPAM::Address" ,
      network       => "2001::/64",
);

# find the desired object from the retrieved list.
my $desired_ipam_address = $result_array[0];

# Submit for removal
my $response = $session->remove( $desired_ipam_address );
```

METHODS

This section describes all the methods that can be used to retrieve the attribute values of an IPAM address object.

conflict_types( )

Use this method to retrieve a list of Discovery conflict types. This attribute is read-only.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get conflict_types
my $value = $ipam_address->conflict_types();
```

dhcp_client_identifier( )

Use this method to retrieve the DHCP client identifier of an IPAM address object. This method applies to IPv4 addresses only.

Parameter

none

Returns

The method returns the DHCP client identifier attribute value.

Example

```
#Get DHCP client identifier
my $identifier = $ipam_address->dhcp_client_identifier();
```

discovered_data( )

Use this method to retrieve the discovered data of an IPAM address object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Data object.

Example

```
#Get discovered_data value
my $discovered_data = $object->discovered_data();
```

discovered_name( )

Use this method to retrieve the discovered name of an IPAM address object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
my $discovered_name = $ipam_address->discovered_name();
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $ipam_address->discover_now_status();
```

duid( )

Use this method to retrieve the DHCPv6 Unique Identifier (DUID) of an IPAM address object.

Parameter

none

Returns

The method returns the DUID value.

Example

```
#Get mac address
my $duid = $ipam_address->duid();
```

discoverer( )

Use this method to retrieve the discoverer of an IPAM address object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $ipam_address->discoverer();
```

extattrs( )

Use this method to retrieve the extensible attributes associated with an IPAM address object. This attribute is read-only and cannot be set.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $ipam_address->extattrs();
```

extensible_attributes( )

Use this method to retrieve the extensible attributes associated with an IPAM address object.

Parameter

none

Returns

The method returns a reference to a hash containing the extensible attributes.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $ipam_address->extensible_attributes();
```

fingerprint( )

Use this method to retrieve DHCP fingerprint description of an IPAM address object. This is a read-only attribute.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get fingerprint
my $fingerprint = $ipam_address->fingerprint();
```

first_discovered( )

Use this method to retrieve the date and time that the IPAM address object was first discovered.

Parameter

none

Returns

The method returns the date and time that the IPAM address object was fisrt discovered.

Example

```
#Get first_discovered
my $first_discovered = $ipam_address->first_discovered();
```

ip_address( )

Use this method to retrieve the IP addresses of an IPAM address object.

Parameter

none

Returns

The method returns the IP address value. The value can be an IPv4 or IPv6 address.

Example

```
#Get IP address
my $ip_address = $ipam_address->ip_address();
```

is_conflict( )

Use this method to find out whether this IPAM address is in conflict with another IPAM address in the system. This method applies to IPv4 addresses only.

Parameter

none

Returns

The method returns true if the IPAM address is in conflict with another in the system, false otherwise.

Example

```
#Get is_conflict
my $conflict = $ipam_address->is_conflict();
```

is_invalid_mac( )

Use this method to retrieve the flag used to indicate whether an invalid MAC address is used. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get is_invalid_mac value
my $is_invalid_mac = $ipam_address->is_invalid_mac();
```

last_discovered( )

Use this method to retrieve the last discovered time of an IPAM address object.

Parameter

none

Returns

The method returns the last discovered value.

Example

```
#Get last discovered
my $last_discovered = $ipam_address->last_discovered();
```

lease_state( )

Use this method to retrieve the lease state of an IPAM address object. This method applies to IPv4 addresses only.

Parameter

none

Returns

The method returns the lease state value. A valid state is any of the following string values: free, backup, active, expired, released, abandoned, and reset.

Example

```
#Get lease state
my $lease_state = $ipam_address->lease_state();
```

mac_address( )

Use this method to retrieve the MAC address of an IPAM address object.

Parameter

none

Returns

The method returns the MAC address value.

Example

```
#Get mac address
my $mac_address = $ipam_address->mac_address();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $ipam_address->ms_ad_user_data();
```

name( )

Use this method to retrieve the name of an IPAM address object.

Parameter

none

Returns

The method returns the name value.

Example

```
#Get name
my $name = $ipam_address->name();
```

netbios_name( )

Use this method to retrieve the NETBIOS name of an IPAM address object.

Parameter

none

Returns

The method returns the NETBIOS name value.

Example

```
#Get netbios name
```

```
my $netbios_name = $ipam_address->netbios_name();
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $ipam_address->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the network device IP address.

Example

```
#Get network_component_ip
my $network_component_ip = $ipam_address->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the network device name.

Example

```
#Get network_component_name
my $network_component_name = $ipam_address->network_component_name();
```

network_component_port_description( )

Use this method to retrieve the description of the network device port that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the network device port description.

Example

```
#Get network_component_port_description
my $network_component_port_description = $ipam_address->network_component_port_description();
```

network_component_port_name( )

Use this method to retrieve the name of the network device port that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the network device port name.

Example

```
#Get network_component_port_name
my $network_component_port_name = $ipam_address->network_component_port_name();
```

network_component_port_number( )

Use this method to retrieve the number of the network device port that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the network device port number.

Example

```
#Get network_component_port_number
my $network_component_port_number = $ipam_address->network_component_port_number();
```

network_component_type( )

Use this method to retrieve the type of the network device that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the network device type.

Example

```
#Get network_component_type
my $network_component_type = $ipam_address->network_component_type();
```

network_view( )

Use this method to retrieve the network view name of an IPAM address object.

Parameter

none

Returns

The method returns the network view name.

Example

```
#Get network view
my $nview_name = $ipam_address->network_view();
```

objects( )

Use this method to retrieve the IPAM address object's associated objects.

Parameter

none

Returns

The method returns a reference to an array of associated objects. Note that this method has to be explicitly requested via Infoblox::Session's return_methods member.

Associated objects can be one or more of the following PAPI objects:

```
Infoblox::DHCP::FixedAddr
Infoblox::DHCP::IPv6FixedAddr
Infoblox::DHCP::Lease
Infoblox::DNS::BulkHost
```

```
Infoblox::DNS::Host
Infoblox::DNS::Record::A
Infoblox::DNS::Record::AAAA
Infoblox::DNS::Record::PTR
```

Example

```
my @retrieved_obj = $session->get(
                                    object     => 'Infoblox::IPAM::Address',
                                    start_addr => '10.0.0.0',
                                    end_addr   => '10.0.0.9',
                                    return_methods => ['+objects'],
                                   );

# Get the associated objects (if any)
my $associated_ref = $retrieved_obj[0]->objects();
```

os( )

Use this method to retrieve the OS of an IPAM address object.

Parameter

none

Returns

The method returns the OS value.

Example

```
#Get os
my $os = $ipam_address->os();
```

port_duplex( )

Use this method to retrieve the duplex setting of the network device port that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the port duplex setting. Returned values, if any, are one of the following:

```
Full
Half
```

Example

```
#Get port_duplex
my $port_duplex = $ipam_address->port_duplex();
```

port_link_status( )

Use this method to retrieve the link status of the network device port that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the port link status of the network device. Returned values, if any, are one of the following:

```
Connected
Not Connected
Unknown
```

Example

```
#Get port_link_status
my $port_link_status = $ipam_address->port_link_status();
```

port_speed( )

Use this method to retrieve the speed of the network device port that is connected to the IPAM address object.

Parameter

none

Returns

The method returns the port speed. Returned values, if any, are one of the following:

```
10M
100M
1G
10G
100G
