      - 2. Run CPAN::Site, instead of CPAN.
      - 3. Add the Infoblox device URL to the top of the CPAN URL list.
      - 4. (Optional) Reduce the number of CPAN fetch methods.
      - 5. Reload the CPAN::Site index.
      - 6. Install the Infoblox package on your management system.

NAME

Infoblox - API Installation and Usage Instructions

VERSION

```
9.0.2-50196-23939c893787
```

Infoblox API Installation Instructions

Infoblox provides a Perl API (application programming interface) to help facilitate the integration of the Infoblox device into network environments. The Infoblox DMAPI (Data and Management API) is a set of packages delivered with the Infoblox device to install the package. Use the usual Perl module installation tools on your management system to install the package. For Windows systems using the ActiveState build of Perl, the package is called PPM ("Perl Package Manager" or "Programmer's Package Manager"). For UNIX systems, the package is called CPAN, a global archive of Perl resources.

Windows Management System

Unix Management System

Windows Management System

To install the Infoblox DMAPI packages on a Windows management system, download and install PPM (from http://www.activestate.com/). Then do the following:

1a. Install Crypt::SSLeay and libwww-perl. for IPv4 connections

1b. Install the supporting libraries. for IPv6 connections

2. PPM 3.x: Add the Infoblox device as a repository.

3. PPM 3.x: Search the Infoblox device for Infoblox packages.

4. PPM 3.x: Install Infoblox packages on your management system.

5. PPM 4.0: Fetch and install Infoblox packages.

Requirements for Windows Management Systems and IPv4 connections

- Perl 5.8.8 or later

- For Windows management systems: the ActiveState version of Perl 5.8.8 or later with PPM 3.x or later

- Crypt::SSLeay version 0.51 or later (and its dependencies: ssleay32.dll and libeay32.dll)

- LWP::UserAgent version 5.813 or later

- XML::Parser

Requirements for Windows Management Systems and IPv6 connections

- Perl 5.14.2 or later

- For Windows management systems: the ActiveState version of Perl 5.14.2 or later with PPM 3.x or later

- LWP::UserAgent version 6.02 or later and relevant dependencies, including LWP::Protocol::https

- Net::INET6Glue

- XML::Parser

1a. Install Crypt::SSLeay and libwww-perl.

1.0 Check your Perl version.

The Crypt::SSLeay package is Perl version sensitive. Perl version 5.8.x requires different packages than 5.10.x. To check the Perl version installed, enter the command: perl -v.

If Perl 5.8.x is installed, the command will return the following:

```
C:\>perl -v
This is perl, v5.8.8 built for MSWin32-x86-multi-thread...
```

If Perl 5.10.x is installed, the command will return the following:

```
C:\>perl -v
This is perl, v5.10.0 built for MSWin32-x86-multi-thread...
```

1.1 Install Crypt-SSLeay.

The Crypt::SSLeay package allows you to make an HTTPS connection to the Infoblox device. Crypt::SSLeay is not part of the core Perl distribution. To check if it is installed, enter the command: ppm query Crypt-SSLeay. If the Crypt-SSLeay package is already installed, the query returns the following result:

```
C:\>ppm query Crypt-SSLeay
Querying target 1 (ActivePerl 5.8.8.817)
1. Crypt-SSLeay [0.51] OpenSSL glue that provides LWP https
```

If the Crypt::SSLeay package is not installed, the query returns the following:

```
C:\>ppm query Crypt-SSLeay
Querying target 1 (ActivePerl 5.8.8.817)
No matches for 'Crypt-SSLeay; see 'help query'.
```

To install Crypt::SSLeay (and its dependencies ssleay32.dll and libeay32.dll) one needs to either build it from the source distribution, or locate a precompiled Crypt-SSLeay.ppd archive.

Note that Crypt::SSLeay does not support TLSv1.1 and higher until version 0.58. To use TLS v1.1 and higher, you must install Crypt::SSLeay version 0.58 and higher.

1.2 Install libwww-perl.

If you need to update LWP::UserAgent, then you will have to install the latest libwww-perl

package.

If the PPM version is 3.x, you will first need to add a PPM repository:

```
C:\> ppm repo add bribes http://www.bribes.org/perl/ppm
```

To install libwww-perl:

```
C:\> ppm install libwww-perl -force
```

1b. Install the supporting libraries.

Infoblox recommends using the ActiveState ppm tool to install the needed modules and dependencies, which may already be installed as part of the perl distribution. For some platforms, some Perl modules may not be available at the time of this writing. an example: Net::INET6Glue, which depends on IO::Socket::INET6; Net::INET6Glue can be compiled following the instructions at

```
http://www.activestate.com/blog/2010/10/how-install-cpan-modules-activeperl
```

using the `Microsoft(r)` SDK section of the instructions. Please refer to ActiveState's website and documentation for further questions.

2. PPM 3.x: Add the Infoblox device as a repository.

The following steps add the Infoblox device as a repository in your PPM 3.x configuration, included with Active Perl from version 5.8.0.802 to 5.8.8.817.

(For PPM 4.0, included with ActivePerl 5.8.8.818 and later, see "5. PPM 4.0: Fetch and install Infoblox packages.")

2.1 Add a PPM repository to the configuration by issuing the ppm repository command;

* For <repo_name>, type a meaningful name for the repository, such as 'Infoblox-device'. * For <ip_addr>, type the IP address that you use for managing the Infoblox device or a resolvable domain name (for a grid, use the address or domain name of the grid master).

```
C:\> ppm repo add <repo_name> https://<ip_addr>/api/dist/ppm
Repositories:
[1] <repo_name>
[2] ActiveState Package Repository
```

(Note that the packages are connected via HTTPS, not HTTP. You only need to add the repository once.)

2.2 To ensure that you have the correct URL, open a Web browser and visit the URL you specified for the repository. If the URL is correct, you can see a directory listing.

3. PPM 3.x: Search the Infoblox device for Infoblox packages.

Start PPM from a command shell:

```
C:\> ppm
PPM - Programmer's Package Manager version 3.4.
Copyright (c) 2001 ActiveState Software Inc.  All Rights Reserved.

Entering interactive shell. Using Term::ReadLine::Perl as readline
library.

Type 'help' to get started.

ppm>

Use PPM to find the Infoblox package:

ppm> search Infoblox
Searching in Active Repositories
1. Infoblox [4.9999990014709] Infoblox Data and Management API 4.x
```

4. PPM 3.x: Install Infoblox packages on your management system.

Install the Infoblox package with PPM:

```
ppm> install Infoblox
====================
Install 'Infoblox' version 4.9999990014709 in ActivePerl 5.8.8.817.
====================
Downloaded 167481 bytes.
...

```
 Successfully installed Infoblox version 4.9999990014709 in ActivePerl
5.8.8.817.
```

5. PPM 4.0: Fetch and install Infoblox packages.

There is a bug in PPM version 4.0 which is included in ActivePerl 5.8.8.818 and 5.8.8.819 which prevents PPM 4.0 from accessing a module archive with https. This bug, and ActiveState's workaround is described at:

http://bugs.activestate.com/show_bug.cgi?id=52508

If you have ActivePerl 5.8.8.818 or 5.8.8.819 (use perl -v at a command line to see), either upgrade to ActivePerl 5.8.8.820 or use the workaround described in the bug:
http://bugs.activestate.com/show_bug.cgi?id=52508

You can also work around the bug by following the steps in section 5.3.

If you have ActivePerl 5.8.8.820 installed, skip the patch step in 5.1 and immediately install the package by following the steps in section 5.2.

5.1 PPM 4.0: Patch lib/ActivePerl/PPM/limited_inc.pm

If you have ActivePerl 5.8.8.818 or 5.8.8.819, please patch your PPM installation so PPM will be able to find modules stored in repositories accessed by https.

As shown in

http://bugs.activestate.com/show_bug.cgi?id=52508

apply this patch one time to your ActiveState PPM installation for each win32 client:

```
 Index: lib/ActivePerl/PPM/limited_inc.pm
 --- lib/ActivePerl/PPM/limited_inc.pm.~1~ Tue Nov 28 16:01:09 2006
 +++ lib/ActivePerl/PPM/limited_inc.pm Tue Nov 28 16:01:09 2006
 @@ -9,7 +9,7 @@
 (my $dir = __FILE__) =~ s,/ActivePerl/PPM/.*,,;
 Make a new directory, naming it something like "ibpack", and then change
the command prompt to that directory.
 if (grep $_ eq $dir, @INC) {
 - shift(@INC) while $INC[0] ne $dir;
 + push(@INC, shift(@INC)) while $INC[0] ne $dir;
 }

 1;
```

To find the full path to this file on your system, use perl -V at the command line. The contents of @INC are at the end of the output. The limited_inc.pm file is in the lib directory, not in the site/lib directory.

If you are unfamiliar with diffs, the + and - notation just means to replace the line:

```
 shift(@INC) while $INC[0] ne $dir;
```

line with the

```
 push(@INC, shift(@INC)) while $INC[0] ne $dir;
```

When complete, the lines of the patched limited_inc.pm should look like:

```
 if (grep $_ eq $dir, @INC) {
 # patch from http://bugs.activestate.com/show_bug.cgi?id=52508
 #     shift(@INC) while $INC[0] ne $dir;
 push(@INC, shift(@INC)) while $INC[0] ne $dir;
 }
```

Continue on to step 5.2

5.2 PPM 4.0: Install the Infoblox modules

Enter the following command, substituting the IP address or resolvable hostname of the Infoblox device for <ip_addr>:

C:\tmp>ppm install https://<ip_addr>/api/dist/ppm/Infoblox.ppd

or you can use the GUI version of PPM by running the GUI, searching for the Infoblox module and installing it in the usual way.

5.3 PPM 4.0 Alternate Work Around to Install

- ThalesGroup

  - SiteMember
  - Subscriber
  - SubscriberSite
- PersonalSmartFolder

Make a new directory and name the directory, for example, "ibpack". Then change the command prompt to that directory.

Make a new directory, naming it something like "ibpack", and then change the command prompt to that directory.

```
C:\> md ibpack

C:\> cd ibpack

C:\ibpack>
```

Next, transfer the files that contain the module distribution from the Infoblox device to your management system using 'lwp-request'. You must transfer two files: a description file, and the main distribution. The description file is always named "Infoblox.ppd".

Enter the following command, substituting the IP address or resolvable hostname of the Infoblox device for <ip_addr>:

```
C:\ibpack> lwp-request https://<ip_addr>/api/dist/ppm/Infoblox.ppd >
Infoblox.ppd
```

View the Infoblox.ppd file:

```
C:\ibpack> type Infoblox.ppd
<?xml version="1.0" encoding="UTF-8"?>
<SOFTPKG NAME="Infoblox" VERSION="4,999999001478,0,0">
<TITLE>Infoblox</TITLE>
<ABSTRACT>Infoblox Data and Management API 4.x</ABSTRACT>
<AUTHOR>Infoblox, Inc.</AUTHOR>
<IMPLEMENTATION>
<CODEBASE HREF="Infoblox-4.999999001478.tar.gz" />
</IMPLEMENTATION>
</SOFTPKG>
```

The file name of the main distribution package is contained in the HREF attributes of the CODEBASE element. In the output shown above, it is "Infoblox-4.999999001478.tar.gz". Use lwp-request to fetch that file.

```
C:\ibpack> lwp-request https://<ip_addr>/api/dist/ppm/Infoblox-
4.999999001478.tar.gz > Infoblox-4.999999001478.tar.gz
```

Use PPM to install the Infoblox DMAPI from the local file system:

```
C:\ibpack> ppm install Infoblox.ppd
Unpacking Infoblox-4.999999001478...done
Generating HTML for Infoblox-4.999999001478...done
Installing to site area...done
64 files installed
```

The installation is complete.

Uninstalling and Reinstalling the Infoblox Package

After you configure PPM to search the Infoblox repository, use the appropriate command to uninstall and reinstall the Infoblox package:

```
ppm> uninstall Infoblox
====================
Remove 'Infoblox' version 4.9999990014709 in ActivePerl 5.8.8.817.
====================
...
Successfully removed Infoblox version 4.9999990014709 from ActivePerl
5.8.8.817.

ppm> install Infoblox
====================
Install 'Infoblox' version 4.9999990014709 in ActivePerl 5.8.8.817.
====================
...
Successfully installed Infoblox version 4.9999990014709 in ActivePerl
5.8.8.817.
```

Unix Management System

Requirements for Unix Management Systems

For IPv4 connections the following are required

- Perl 5.8.8 or later

- Crypt::SSLeay version 0.51 or later

- RecordNamePolicy
- RestartBannerSetting
- RIR
  - Organization
- RootNameServer
- RPZ
  - ThreatDetails
- ScheduledBackup
- ScheduledTask
  - ChangedObject
- ScheduleSetting
- ServiceRestart
  - Group
    - Order
    - Schedule
  - Request
    - ChangedObject
  - Status
- SmartFolder
  - GroupBy
  - GroupByValue
  - QueryItem
- SmartFolderChildren
- SNMP

IFMap

- CACertificate
- Client
  - Credentials

IPAM

- Address
- DiscoveryTask
  - VServer
- Statistics
- TCPPort

LDAP

- AuthService

- LWP::UserAgent version 5.813 or later

- XML::Parser

For IPv6 connections the following are required

- Perl 5.14.2 or later

- LWP::UserAgent version 6.02 or later and relevant dependencies, including LWP::Protocol::https

- Net::INET6Glue

- XML::Parser

to easily install the required libraries it is recommented to use CPAN, after installing perl run

```
perl -e shell -MCPAN
```

and once configured simply run

```
install LWP::UserAgent
install XML::Parser
```

and the other packages you need depending on IPv4 or IPv6 accessibility.

DIRECT INSTALLATION

To install the Infoblox DMAPI packages on a UNIX management system, first download and install the API package from:

```
https://<ip_addr>/api/dist/CPAN/authors/id/INFOBLOX/
```

where ip_addr is the IP address of the appliance. Then locate and download the file Infoblox-xxxxxxx.tar.gz where xxxxxxx is an integer depending on your API package version.

After you download the package, extract it to a temporary directory with:

```
tar xvfz Infoblox-xxxxxxx.tar.gz
```

Then execute the following commands:

```
cd Infoblox-xxxxxxx/
perl Makefile.PL
make
make install
```

Optionally, before you install, test the package by running:

```
make test
```

The installation is complete.

Infoblox API Usage Guidelines

The usage instructions are provided to assist you in using the Infoblox API.

Library options

The Infoblox library can optionally be invoked by supplying the following options

```
  :accessrights     - If this is specified,
'Infoblox::Grid::Admin::Group' sends a request for
'Infoblox::Grid::Admin::Permission' to set the member 'permission_list'.
  :noaccessrights   - If this is specified,
'Infoblox::Grid::Admin::Group' does not send a request for
'Infoblox::Grid::Admin::Permission' and the member 'permission_list' is
not set. This is specified by default.
  :ipv6connection   - This will allow the API to connect to IPv6 members.
  :hostaddress      - if this is specified the new
'Infoblox::DHCP::HostAddr' and 'Infoblox::DHCP::IPv6HostAddr' types will
be supported, see 'Infoblox::DNS::Host' for more information
```

for example, to enable :ipv6connection the use line would be

```
  use Infoblox qw ( :ipv6connection );
```

UTF8 Considerations

- EA_Mapping
- Server
- **MasterGrid**
- Grid
- **Notification**
- REST
  - Endpoint
  - Template
  - TemplateInstance
  - TemplateParameter
- Rule
- RuleExpressionOp
- **OCSP**
- Responder
- **Session**
- **Util**

If there are utf-8 characters in your script, remember to use the pragma 'use utf8'. If you need more information, please see http://search.cpan.org/~nwclark/perl-5.8.8/lib/utf8.pm on the utf8 pragma.

`search()` Considerations

When using the `search()` method, you can retrieve more information than expected. Include additional checks for exact matches.

Example

```
my @result_array = $session->search(
       "object" => "Infoblox::DNS::Record::A",
       "name" => "infoblox.com" );

my $obj;

foreach my $match (@result_array)
{
   if( ($match->name() eq "infoblox.com") && ($match->ipv4addr()
eq "2.2.2.2") )
   {
      print "Matches\n";
      $obj = $match;
   }
}
```

Object inheritance

Values set in PAPI object members might differ from the effective value used for that particular member during product operation, which could be a value inherited from the Grid or the Grid Member depending on the particular object in question and the state of the object override flags.

Alternate installation instructions

The following is provided for reference purposes only, as CPAN::Site has not supported this installation method for some time.

CPAN INSTALLATION (obsolete, only for CPAN::Site pre 1.02)

To install the Infoblox DMAPI packages on a UNIX management system, first download and install ActivePerl (from www.activestate.com), and then do the following steps:

1. Install Crypt::SSLeay and CPAN::Site on your management system.

2. Run CPAN::Site, instead of CPAN.

3. Add the Infoblox device URL to the top of the CPAN URL list.

4. (Optional) Reduce the number of CPAN fetch methods.

5. Reload the CPAN::Site index.

6. Install the Infoblox package on your management system.

Typically, the installation is done at the root level. See perlfaq8 under the question "How do I keep my own module/library directory?" for instructions on how to install a module as a user other than root.

If you have never used CPAN on the client UNIX machine, you will need to follow the instructions, when you run it for the first time, you will be prompted for many configuration variables. Follow the procedure at 0. First Time CPAN Installation

CPAN::Site Overview

The Infoblox modules are installed using a variant of CPAN named CPAN::Site. See

http://search.cpan.org/search?mode=module&query=CPAN%3A%3ASite

for more information on CPAN::Site.

In the usual CPAN model, there is a single CPAN repository, and every copy is a full and complete copy of every available package. In the CPAN::Site model, there are multiple repositories which may have a given module. As the Infoblox modules are deployed with

CPAN::Site, you must use CPAN::Site instead of CPAN to install them. This is covered in more detail in step 2. If you use CPAN instead of CPAN::Site, typically the installation process will not find the Infoblox module in step 5.

One consequence of using CPAN::Site is the installation searches multiple sites for the same set of files, finding some of them in some locations but not in others. This is a normal result. Additionally, CPAN has the ability to search for and fetch files using several different mechanisms: curl, FTP, lynx, ncftpget, wget, and LWP. Both CPAN and CPAN::Site use each of these methods in turn when it tries to find files. If the CPAN configuration lists many sites in its URL list and many access methods, the installation may take a long time while CPAN::Site tries each of the access methods on each of the listed sites. For this reason, Infoblox recommends that you reduce the number of sites in the URL list and the number of access methods as described in step 4.

If you are installing a new version of the Infoblox modules and your urllist configuration still includes the Infoblox appliance, skip directly to steps 5 and 6.

First Time CPAN Installation

If you have never used CPAN on this client machine before, enter the following command:

```
[root@lx2 ~]# perl -MCPAN -e shell
```

and follow the prompts through the CPAN configuration. You can accept all of the defaults, except for the list of CPAN sites close to your physical location. Navigate the menus and choose 1 or 2 CPAN sites that are close to your site. When your configuration choices are complete, exit CPAN by typing exit at the prompt.

1. Install Crypt::SSLeay and CPAN::Site on your management system.

The Crypt::SSLeay package allows you to make an HTTPS connection to the Infoblox device. If Crypt::SSLeay is not already installed, open a terminal window, login as the root user, and use CPAN to install the Crypt::SSLeay package and all its dependencies:

```
lx> perl -MCPAN -e 'install Crypt::SSLeay'
```

Install the CPAN::Site module:

```
lx> perl -MCPAN -e 'install CPAN::Site'
```

When the system prompts: "Running client or server?", enter 'client'. The installation process is asking if you want to install CPAN::Site as a server or as a client. Since CPAN::Site retrieves the Infoblox modules from a server, CPAN::Site acts as a client.

2. Run CPAN::Site, instead of CPAN.

Use CPAN::Site instead of CPAN:

```
lx> perl -MCPAN::Site -e shell
CPAN: File::HomeDir loaded ok

cpan shell -- CPAN exploration and modules installation (v1.87)
ReadLine support enabled
```

You must use CPAN::Site every time to access the Infoblox modules.

3. Add the Infoblox device URL to the top of the CPAN URL list.

3.0 You can manipulate the contents of the urllist with the usual perl functions push, pop, shift and unshift. push and pop operate on the end of the list, while shift and unshift operate on the beginning of the list. To empty the urllist, issue repeated shift or pop operands like this:

```
cpan> o conf urllist
urllist
[ftp://mirrors.kernel.org/pub/CPAN]
[http://mirrors.kernel.org/pub/CPAN]
Type 'o conf' to view all configuration items

cpan> o conf urllist shift

cpan> o conf urllist shift

cpan> o conf urllist
urllist
Type 'o conf' to view all configuration items
```

You can put an item on the list at the beginning with unshift and at the end of the list with

push:

```
 cpan> o conf urllist unshift ftp://mirrors.kernel.org/pub/CPAN

 cpan> o conf urllist push ftp://bogus.site.at.end.of.list/CPAN

 cpan> o conf urllist
 urllist
  [ftp://mirrors.kernel.org/pub/CPAN]
  [ftp://bogus.site.at.end.of.list/CPAN]
Type 'o conf' to view all configuration items
```

When you finish configuring the urllist, you must have the Infoblox appliance as the first item in the list. This is a requirement of CPAN::Site. The best configuration of urllist is a two-item list with the Infoblox appliance first and one other close, fast CPAN site second. For example, at the Infoblox headquarters a good set of choices for urllist is:

```
 cpan> o conf urllist
 urllist
  [https://<ip_addr>/api/dist/CPAN]
  [ftp://mirrors.kernel.org/pub/CPAN]
Type 'o conf' to view all configuration items
```

The complete list of CPAN sites can be found at:

http://www.cpan.org/SITES.html

3.1 Configure the Infoblox device first in the CPAN URL list, so that CPAN::Site finds it first when searching for packages. Type the IP address or domain name of your Infoblox device for <ip_addr> (for a grid, use the address of the grid master):

cpan> o conf urllist unshift https://<ip_addr>/api/dist/CPAN

(Note: You only need to add the repository to the URL list once.)

3.2 You must have at least one other normal CPAN site in the list in case your client needs other public packages. The following is a sample URL list for a set of CPAN sites in North America:

```
 cpan> o conf urllist
 urllist
  [https://<ip_addr>/api/dist/CPAN]
  [ftp://mirrors.kernel.org/pub/CPAN]
  [ftp://cpan.pair.com/pub/CPAN/]
Type 'o conf' to view all configuration items
```

If you do not have any other CPAN sites in your URL list, add at least one before continuing. Use the command

o conf urllist push <url_string>

3.3 To ensure that you have the correct URL for the Infoblox modules, open a Web browser and visit the URL you specified for the repository, in this example https://<ip_addr>/api/dist/CPAN. If the URL is correct, you can see a directory listing of the module files.

3.4 Save your CPAN configuration:

```
 cpan> o conf commit
commit: wrote '/usr/lib/perl5/5.8.8/CPAN/Config.pm'
```

4. (Optional) Reduce the number of CPAN fetch methods.

By reducing the number of CPAN fetch methods, you can shorten the installation process. For an explanation why Infoblox recommends this step, see the note in the introduction (before step 1).

```
 CPAN (and CPAN::Site) supports up to six different ways to search for
and fetch files: curl, FTP, lynx, ncftpget, wget, and LWP. Infoblox
recommends that you choose the method that work best for you and only
configure those methods. For the typical cases, Infoblox recommends
keeping LWP, FTP, and ncftpget enabled and disabling curl, lynx and wget.
To disable a fetch method, set it to an empty string and then commit the
configuration. In the example below, you first display the configuration
parameters for curl, lynx, and wget, and then set them to an empty
string:

 cpan> o conf curl
 curl                                [/usr/bin/curl]

 cpan> o conf curl ""
 curl                                []

 cpan> o conf lynx
```

```
 lynx                            [/usr/bin/lynx]

 cpan> o conf lynx ""
 lynx                            []

 cpan> o conf wget
 wget                            [/usr/bin/wget]

 cpan> o conf wget ""
 wget                            []

 cpan> o conf commit
 commit: wrote '/usr/lib/perl5/5.8.8/CPAN/Config.pm'
```

5. Reload the CPAN::Site index.

Use CPAN to reload the CPAN::Site index:

```
 cpan> reload index
 CPAN: Storable loaded ok
 Going to read /root/.cpan/Metadata
 Database was generated on Sat, 09 Sep 2006 22:32:52 GMT
 CPAN: LWP::UserAgent loaded ok
 Fetching with LWP:
 https://<ip_addr>/api/dist/CPAN/authors/01mailrc.txt.gz
 ...
 Fetching with LWP:
 https://<ip_addr>/api/dist/CPAN/modules/03modlist.data.gz
 LWP failed with code[404] message[Not Found]
 Fetching with LWP:
 ftp://mirrors.kernel.org/pub/CPAN/modules/03modlist.data.gz
 Going to read /root/.cpan/sources/modules/03modlist.data.gz
 Going to write /root/.cpan/Metadata
```

Note: Unlike CPAN, CPAN::Site is designed so that some of the files that describe the available packages are not found in all of the locations in your URL list. It is normal to see some "file not found" errors during the index reload.

6. Install the Infoblox package on your management system.

The usual CPAN process for installing Perl modules is:

6.1 Search

6.2 Test

6.3 Install

6.4 Uninstall and Reinstall

6.1 Search

Use the m operator to search for the Infoblox module:

```
 cpan> m /Infoblox/
 CPAN: Storable loaded ok
 Going to read /root/.cpan/Metadata
 Database was generated on Mon, 18 Sep 2006 06:29:55 GMT
 CPAN: LWP::UserAgent loaded ok
 . . .
 Fetching with LWP:
 https://<ip_addr>/api/dist/CPAN/site/01mailrc.txt.gz
 Going to read /root/.cpan/sources/site/01mailrc.txt.gz
 Module id = Infoblox
 CPAN_USERID  INFOBLOX (Infoblox Technical Support
<support@infoblox.com>)
 CPAN_VERSION 4.9999990014709
 CPAN_FILE    INFOBLOX/Infoblox-4.9999990014709.tar.gz
 INST_FILE    (not installed)
```

If the search cannot find the Infoblox modules:

a. Ensure that you are using CPAN::Site, not CPAN as shown in 2. Run CPAN::Site, instead of CPAN. b. Check the Infoblox appliance in the urllist as shown in step 3.3.

6.2 Test

You can optionally test the package before the installation:

```
 cpan> test Infoblox
 Running test for module Infoblox
 Running make for Infoblox-4.999990014709.tar.gz
 ...
 All tests successful.
 Files=1, Tests=1,  0 wallclock secs ( 0.74 cusr +  0.08 csys =  0.82
CPU)
```

```
 /usr/bin/make test - OK
```

6.3 Install

Install the Infoblox package:

```
 cpan> install Infoblox
 Running install for module Infoblox
 Running make for INFOBLOX/Infoblox-4.9999990014709.tar.gz
 ...
 Writing /usr/lib/perl5/site_perl/5.8.8/i386-linux-thread-
multi/auto/Infoblox/.packlist
 Appending installation info to /usr/lib/perl5/5.8.8/i386-linux-thread-
multi/perllocal.pod
 /usr/bin/make install  -- OK
```

To exit the CPAN::Site shell:

```
 cpan> quit
```

The installation is complete.

6.4 Uninstalling and Reinstalling the Infoblox Package

Although not directly supported by CPAN, it is simple to uninstall the Infoblox package using published techniques. One way to do it is provided by the modrm program that is described in the ExtUtils::Packlist documentation. See http://search.cpan.org/~yves/ExtUtils-Install-1.41/lib/ExtUtils/Packlist.pm#EXAMPLE for the modrm program. To reinstall it, repeat steps 5 and 6 above.

```

Infoblox API Installation Instructions

Infoblox provides a Perl API (application programming interface) to help facilitate the integration of the Infoblox device into network environments. The Infoblox DMAPI (Data and Management API) is a set of packages delivered with the Infoblox device to install the package. Use the usual Perl module installation tools on your management system to install the package. For Windows systems using the ActiveState build of Perl, the package is called PPM ("Perl Package Manager" or "Programmer's Package Manager"). For UNIX systems, the package is called CPAN, a global archive of Perl resources.

Windows Management System

Unix Management System

Windows Management System

To install the Infoblox DMAPI packages on a Windows management system, download and install PPM (from http://www.activestate.com/). Then do the following:

1a. Install Crypt::SSLeay and libwww-perl. for IPv4 connections

1b. Install the supporting libraries. for IPv6 connections

2. PPM 3.x: Add the Infoblox device as a repository.

3. PPM 3.x: Search the Infoblox device for Infoblox packages.

4. PPM 3.x: Install Infoblox packages on your management system.

5. PPM 4.0: Fetch and install Infoblox packages.

Requirements for Windows Management Systems and IPv4 connections

- Perl 5.8.8 or later

- For Windows management systems: the ActiveState version of Perl 5.8.8 or later with PPM 3.x or later

- Crypt::SSLeay version 0.51 or later (and its dependencies: ssleay32.dll and libeay32.dll)

- LWP::UserAgent version 5.813 or later

- XML::Parser

Requirements for Windows Management Systems and IPv6 connections

- Perl 5.14.2 or later

- For Windows management systems: the ActiveState version of Perl 5.14.2 or later with PPM 3.x or later

- LWP::UserAgent version 6.02 or later and relevant dependencies, including LWP::Protocol::https

- Net::INET6Glue

- XML::Parser

1a. Install Crypt::SSLeay and libwww-perl.

1.0 Check your Perl version.

The Crypt::SSLeay package is Perl version sensitive. Perl version 5.8.x requires different packages than 5.10.x. To check the Perl version installed, enter the command: perl -v.

If Perl 5.8.x is installed, the command will return the following:

```
C:\>perl -v
This is perl, v5.8.8 built for MSWin32-x86-multi-thread...
```

If Perl 5.10.x is installed, the command will return the following:

```
C:\>perl -v
This is perl, v5.10.0 built for MSWin32-x86-multi-thread...
```

1.1 Install Crypt-SSLeay.

The Crypt::SSLeay package allows you to make an HTTPS connection to the Infoblox device. Crypt::SSLeay is not part of the core Perl distribution. To check if it is installed, enter the command: ppm query Crypt-SSLeay. If the Crypt-SSLeay package is already installed, the query returns the following result:

```
C:\>ppm query Crypt-SSLeay
Querying target 1 (ActivePerl 5.8.8.817)
1. Crypt-SSLeay [0.51] OpenSSL glue that provides LWP https
```

If the Crypt::SSLeay package is not installed, the query returns the following:

```
C:\>ppm query Crypt-SSLeay
Querying target 1 (ActivePerl 5.8.8.817)
No matches for 'Crypt-SSLeay; see 'help query'.
```

To install Crypt::SSLeay (and its dependencies ssleay32.dll and libeay32.dll) one needs to either build it from the source distribution, or locate a precompiled Crypt-SSLeay.ppd archive.

Note that Crypt::SSLeay does not support TLSv1.1 and higher until version 0.58. To use TLS v1.1 and higher, you must install Crypt::SSLeay version 0.58 and higher.

1.2 Install libwww-perl.

If you need to update LWP::UserAgent, then you will have to install the latest libwww-perl package.

If the PPM version is 3.x, you will first need to add a PPM repository:

```
C:\> ppm repo add bribes http://www.bribes.org/perl/ppm
```

To install libwww-perl:

```
C:\> ppm install libwww-perl -force
```

1b. Install the supporting libraries.

Infoblox recommends using the ActiveState ppm tool to install the needed modules and dependencies, which may already be installed as part of the perl distribution. For some platforms, some Perl modules may not be available at the time of this writing. an example:

Net::INET6Glue, which depends on IO::Socket::INET6; Net::INET6Glue can be compiled following the instructions at

http://www.activestate.com/blog/2010/10/how-install-cpan-modules-activeperl

using the Microsoft(r) SDK section of the instructions. Please refer to ActiveState's website and documentation for further questions.

2. PPM 3.x: Add the Infoblox device as a repository.

The following steps add the Infoblox device as a repository in your PPM 3.x configuration, included with Active Perl from version 5.8.0.802 to 5.8.8.817.

(For PPM 4.0, included with ActivePerl 5.8.8.818 and later, see "5. PPM 4.0: Fetch and install Infoblox packages.")

2.1 Add a PPM repository to the configuration by issuing the ppm repository command;

* For <repo_name>, type a meaningful name for the repository, such as 'Infoblox-device'. * For <ip_addr>, type the IP address that you use for managing the Infoblox device or a resolvable domain name (for a grid, use the address or domain name of the grid master).

```
C:\> ppm repo add <repo_name> https://<ip_addr>/api/dist/ppm
Repositories:
[1] <repo_name>
[2] ActiveState Package Repository
```

(Note that the packages are connected via HTTPS, not HTTP. You only need to add the repository once.)

2.2 To ensure that you have the correct URL, open a Web browser and visit the URL you specified for the repository. If the URL is correct, you can see a directory listing.

3. PPM 3.x: Search the Infoblox device for Infoblox packages.

Start PPM from a command shell:

```
C:\> ppm
PPM - Programmer's Package Manager version 3.4.
Copyright (c) 2001 ActiveState Software Inc.  All Rights Reserved.

Entering interactive shell. Using Term::ReadLine::Perl as readline library.

Type 'help' to get started.

ppm>

Use PPM to find the Infoblox package:

ppm> search Infoblox
Searching in Active Repositories
1. Infoblox [4.9999990014709] Infoblox Data and Management API 4.x
```

4. PPM 3.x: Install Infoblox packages on your management system.

Install the Infoblox package with PPM:

```
ppm> install Infoblox
====================
Install 'Infoblox' version 4.9999990014709 in ActivePerl 5.8.8.817.
====================
Downloaded 167481 bytes.
...
Successfully installed Infoblox version 4.9999990014709 in ActivePerl 5.8.8.817.
```

5. PPM 4.0: Fetch and install Infoblox packages.

There is a bug in PPM version 4.0 which is included in ActivePerl 5.8.8.818 and 5.8.8.819 which prevents PPM 4.0 from accessing a module archive with https. This bug, and ActiveState's workaround is described at:

http://bugs.activestate.com/show_bug.cgi?id=52508

If you have ActivePerl 5.8.8.818 or 5.8.8.819 (use perl -v at a command line to see), either upgrade to ActivePerl 5.8.8.820 or use the workaround described in the bug: http://bugs.activestate.com/show_bug.cgi?id=52508

You can also work around the bug by following the steps in section 5.3.

If you have ActivePerl 5.8.8.820 installed, skip the patch step in 5.1 and immediately install the package by following the steps in section 5.2.

5.1 PPM 4.0: Patch lib/ActivePerl/PPM/limited_inc.pm

If you have ActivePerl 5.8.8.818 or 5.8.8.819, please patch your PPM installation so PPM will be able to find modules stored in repositories accessed by https.

As shown in

http://bugs.activestate.com/show_bug.cgi?id=52508

apply this patch one time to your ActiveState PPM installation for each win32 client:

```
Index: lib/ActivePerl/PPM/limited_inc.pm
--- lib/ActivePerl/PPM/limited_inc.pm.~1~ Tue Nov 28 16:01:09 2006
+++ lib/ActivePerl/PPM/limited_inc.pm Tue Nov 28 16:01:09 2006
@@ -9,7 +9,7 @@
(my $dir = __FILE__) =~ s,/ActivePerl/PPM/.*,,;
Make a new directory, naming it something like "ibpack", and then change the command prompt to that
directory.
if (grep $_ eq $dir, @INC) {
- shift(@INC) while $INC[0] ne $dir;
+ push(@INC, shift(@INC)) while $INC[0] ne $dir;
}

1;
```

To find the full path to this file on your system, use perl -V at the command line. The contents of @INC are at the end of the output. The limited_inc.pm file is in the lib directory, not in the site/lib directory.

If you are unfamiliar with diffs, the + and - notation just means to replace the line:

```
shift(@INC) while $INC[0] ne $dir;
```

line with the

```
push(@INC, shift(@INC)) while $INC[0] ne $dir;
```

When complete, the lines of the patched limited_inc.pm should look like:

```
if (grep $_ eq $dir, @INC) {
# patch from http://bugs.activestate.com/show_bug.cgi?id=52508
#    shift(@INC) while $INC[0] ne $dir;
push(@INC, shift(@INC)) while $INC[0] ne $dir;
}
```

Continue on to step 5.2

5.2 PPM 4.0: Install the Infoblox modules

Enter the following command, substituting the IP address or resolvable hostname of the Infoblox device for <ip_addr>:

C:\tmp>ppm install https://<ip_addr>/api/dist/ppm/Infoblox.ppd

or you can use the GUI version of PPM by running the GUI, searching for the Infoblox module and installing it in the usual way.

5.3 PPM 4.0 Alternate Work Around to Install

Make a new directory and name the directory, for example, "ibpack". Then change the command prompt to that directory.

Make a new directory, naming it something like "ibpack", and then change the command prompt to that directory.

```
C:\> md ibpack

C:\> cd ibpack

C:\ibpack>
```

Next, transfer the files that contain the module distribution from the Infoblox device to your management system using 'lwp-request'. You must transfer two files: a description file, and the main distribution. The description file is always named "Infoblox.ppd".

Enter the following command, substituting the IP address or resolvable hostname of the Infoblox device for <ip_addr>:

```
C:\ibpack> lwp-request https://<ip_addr>/api/dist/ppm/Infoblox.ppd > Infoblox.ppd
```

View the Infoblox.ppd file:

```
C:\ibpack> type Infoblox.ppd
<?xml version="1.0" encoding="UTF-8"?>
<SOFTPKG NAME="Infoblox" VERSION="4,999999001478,0,0">
<TITLE>Infoblox</TITLE>
<ABSTRACT>Infoblox Data and Management API 4.x</ABSTRACT>
<AUTHOR>Infoblox, Inc.</AUTHOR>
<IMPLEMENTATION>
<CODEBASE HREF="Infoblox-4.999999001478.tar.gz" />
</IMPLEMENTATION>
</SOFTPKG>
```

The file name of the main distribution package is contained in the HREF attributes of the CODEBASE element. In the output shown above,

it is "Infoblox-4.999999001478.tar.gz". Use lwp-request to fetch that file.

```
 C:\ibpack> lwp-request https://<ip_addr>/api/dist/ppm/Infoblox-4.999999001478.tar.gz > Infoblox-
4.999999001478.tar.gz
```

Use PPM to install the Infoblox DMAPI from the local file system:

```
 C:\ibpack> ppm install Infoblox.ppd
 Unpacking Infoblox-4.999999001478...done
 Generating HTML for Infoblox-4.999999001478...done
 Installing to site area...done
 64 files installed
```

The installation is complete.

Uninstalling and Reinstalling the Infoblox Package

After you configure PPM to search the Infoblox repository, use the appropriate command to uninstall and reinstall the Infoblox package:

```
 ppm> uninstall Infoblox
 ====================
 Remove 'Infoblox' version 4.9999990014709 in ActivePerl 5.8.8.817.
 ====================
 ...
 Successfully removed Infoblox version 4.9999990014709 from ActivePerl 5.8.8.817.

 ppm> install Infoblox
 ====================
 Install 'Infoblox' version 4.9999990014709 in ActivePerl 5.8.8.817.
 ====================
 ...
 Successfully installed Infoblox version 4.9999990014709 in ActivePerl 5.8.8.817.
```

Unix Management System

Requirements for Unix Management Systems

For IPv4 connections the following are required

- Perl 5.8.8 or later

- Crypt::SSLeay version 0.51 or later

- LWP::UserAgent version 5.813 or later

- XML::Parser

For IPv6 connections the following are required

- Perl 5.14.2 or later

- LWP::UserAgent version 6.02 or later and relevant dependencies, including LWP::Protocol::https

- Net::INET6Glue

- XML::Parser

to easily install the required libraries it is recommented to use CPAN, after installing perl run

```
 perl -e shell -MCPAN
```

and once configured simply run

```
 install LWP::UserAgent
 install XML::Parser
```

and the other packages you need depending on IPv4 or IPv6 accessibility.

DIRECT INSTALLATION

To install the Infoblox DMAPI packages on a UNIX management system, first download and install the API package from:

```
 https://<ip_addr>/api/dist/CPAN/authors/id/INFOBLOX/
```

where ip_addr is the IP address of the appliance. Then locate and download the file Infoblox-xxxxxxx.tar.gz where xxxxxxx is an integer depending on your API package version.

After you download the package, extract it to a temporary directory with:

```
 tar xvfz Infoblox-xxxxxxx.tar.gz
```

Then execute the following commands:

```
cd Infoblox-xxxxxxx/
perl Makefile.PL
make
make install
```

Optionally, before you install, test the package by running:

```
make test
```

The installation is complete.

Infoblox API Usage Guidelines

The usage instructions are provided to assist you in using the Infoblox API.

Library options

The Infoblox library can optionally be invoked by supplying the following options

```
  :accessrights     - If this is specified, 'Infoblox::Grid::Admin::Group' sends a request for
'Infoblox::Grid::Admin::Permission' to set the member 'permission_list'.
  :noaccessrights   - If this is specified, 'Infoblox::Grid::Admin::Group' does not send a request for
'Infoblox::Grid::Admin::Permission' and the member 'permission_list' is not set. This is specified by
default.
  :ipv6connection   - This will allow the API to connect to IPv6 members.
  :hostaddress      - if this is specified the new 'Infoblox::DHCP::HostAddr' and
'Infoblox::DHCP::IPv6HostAddr' types will be supported, see 'Infoblox::DNS::Host' for more information
```

for example, to enable :ipv6connection the use line would be

```
  use Infoblox qw ( :ipv6connection );
```

UTF8 Considerations

If there are utf-8 characters in your script, remember to use the pragma 'use utf8'. If you need more information, please see http://search.cpan.org/~nwclark/perl-5.8.8/lib/utf8.pm on the utf8 pragma.

`search()` Considerations

When using the `search()` method, you can retrieve more information than expected. Include additional checks for exact matches.

Example

```
my @result_array = $session->search(
       "object" => "Infoblox::DNS::Record::A",
       "name" => "infoblox.com" );

my $obj;

foreach my $match (@result_array)
{
   if( ($match->name() eq "infoblox.com") && ($match->ipv4addr() eq "2.2.2.2") )
   {
      print "Matches\n";
      $obj = $match;
   }
}
```

Object inheritance

Values set in PAPI object members might differ from the effective value used for that particular member during product operation, which could be a value inherited from the Grid or the Grid Member depending on the particular object in question and the state of the object override flags.

Alternate installation instructions

The following is provided for reference purposes only, as CPAN::Site has not supported this installation method for some time.

CPAN INSTALLATION (obsolete, only for CPAN::Site pre 1.02)

To install the Infoblox DMAPI packages on a UNIX management system, first download and install ActivePerl (from www.activestate.com), and then do the following steps:

1. Install Crypt::SSLeay and CPAN::Site on your management system.

2. Run CPAN::Site, instead of CPAN.

3. Add the Infoblox device URL to the top of the CPAN URL list.

4. (Optional) Reduce the number of CPAN fetch methods.

5. Reload the CPAN::Site index.

6. Install the Infoblox package on your management system.

Typically, the installation is done at the root level. See perlfaq8 under the question "How do I keep my own module/library directory?" for instructions on how to install a module as a user other than root.

If you have never used CPAN on the client UNIX machine, you will need to follow the instructions, when you run it for the first time, you will be prompted for many configuration variables. Follow the procedure at 0. First Time CPAN Installation

CPAN::Site Overview

The Infoblox modules are installed using a variant of CPAN named CPAN::Site. See

http://search.cpan.org/search?mode=module&query=CPAN%3A%3ASite

for more information on CPAN::Site.

In the usual CPAN model, there is a single CPAN repository, and every copy is a full and complete copy of every available package. In the CPAN::Site model, there are multiple repositories which may have a given module. As the Infoblox modules are deployed with CPAN::Site, you must use CPAN::Site instead of CPAN to install them. This is covered in more detail in step 2. If you use CPAN instead of CPAN::Site, typically the installation process will not find the Infoblox module in step 5.

One consequence of using CPAN::Site is the installation searches multiple sites for the same set of files, finding some of them in some locations but not in others. This is a normal result. Additionally, CPAN has the ability to search for and fetch files using several different mechanisms: curl, FTP, lynx, ncftpget, wget, and LWP. Both CPAN and CPAN::Site use each of these methods in turn when it tries to find files. If the CPAN configuration lists many sites in its URL list and many access methods, the installation may take a long time while CPAN::Site tries each of the access methods on each of the listed sites. For this reason, Infoblox recommends that you reduce the number of sites in the URL list and the number of access methods as described in step 4.

If you are installing a new version of the Infoblox modules and your urllist configuration still includes the Infoblox appliance, skip directly to steps 5 and 6.

First Time CPAN Installation

If you have never used CPAN on this client machine before, enter the following command:

```
[root@lx2 ~]# perl -MCPAN -e shell
```

and follow the prompts through the CPAN configuration. You can accept all of the defaults, except for the list of CPAN sites close to your physical location. Navigate the menus and choose 1 or 2 CPAN sites that are close to your site. When your configuration choices are complete, exit CPAN by typing exit at the prompt.

1. Install Crypt::SSLeay and CPAN::Site on your management system.

The Crypt::SSLeay package allows you to make an HTTPS connection to the Infoblox device. If Crypt::SSLeay is not already installed, open a terminal window, login as the root user, and use CPAN to install the Crypt::SSLeay package and all its dependencies:

```
lx> perl -MCPAN -e 'install Crypt::SSLeay'
```

Install the CPAN::Site module:

```
lx> perl -MCPAN -e 'install CPAN::Site'
```

When the system prompts: "Running client or server?", enter 'client'. The installation process is asking if you want to install CPAN::Site as a server or as a client. Since CPAN::Site retrieves the Infoblox modules from a server, CPAN::Site acts as a client.

2. Run CPAN::Site, instead of CPAN.

Use CPAN::Site instead of CPAN:

```
lx> perl -MCPAN::Site -e shell
CPAN: File::HomeDir loaded ok

cpan shell -- CPAN exploration and modules installation (v1.87)
ReadLine support enabled
```

You must use CPAN::Site every time to access the Infoblox modules.

3. Add the Infoblox device URL to the top of the CPAN URL list.

3.0 You can manipulate the contents of the urllist with the usual perl functions push, pop, shift and unshift. push and pop operate on the end of the list, while shift and unshift operate on the beginning of the list. To empty the urllist, issue repeated shift or pop operands like this:

```
 cpan> o conf urllist
 urllist
  [ftp://mirrors.kernel.org/pub/CPAN]
  [http://mirrors.kernel.org/pub/CPAN]
 Type 'o conf' to view all configuration items

 cpan> o conf urllist shift

 cpan> o conf urllist shift

 cpan> o conf urllist
 urllist
Type 'o conf' to view all configuration items
```

You can put an item on the list at the beginning with unshift and at the end of the list with push:

```
 cpan> o conf urllist unshift ftp://mirrors.kernel.org/pub/CPAN

 cpan> o conf urllist push ftp://bogus.site.at.end.of.list/CPAN

 cpan> o conf urllist
 urllist
  [ftp://mirrors.kernel.org/pub/CPAN]
  [ftp://bogus.site.at.end.of.list/CPAN]
Type 'o conf' to view all configuration items
```

When you finish configuring the urllist, you must have the Infoblox appliance as the first item in the list. This is a requirement of CPAN::Site. The best configuration of urllist is a two-item list with the Infoblox appliance first and one other close, fast CPAN site second. For example, at the Infoblox headquarters a good set of choices for urllist is:

```
 cpan> o conf urllist
 urllist
  [https://<ip_addr>/api/dist/CPAN]
  [ftp://mirrors.kernel.org/pub/CPAN]
Type 'o conf' to view all configuration items
```

The complete list of CPAN sites can be found at:

http://www.cpan.org/SITES.html

3.1 Configure the Infoblox device first in the CPAN URL list, so that CPAN::Site finds it first when searching for packages. Type the IP address or domain name of your Infoblox device for <ip_addr> (for a grid, use the address of the grid master):

cpan> o conf urllist unshift https://<ip_addr>/api/dist/CPAN

(Note: You only need to add the repository to the URL list once.)

3.2 You must have at least one other normal CPAN site in the list in case your client needs other public packages. The following is a sample URL list for a set of CPAN sites in North America:

```
 cpan> o conf urllist
 urllist
  [https://<ip_addr>/api/dist/CPAN]
  [ftp://mirrors.kernel.org/pub/CPAN]
  [ftp://cpan.pair.com/pub/CPAN/]
Type 'o conf' to view all configuration items
```

If you do not have any other CPAN sites in your URL list, add at least one before continuing. Use the command

o conf urllist push <url_string>

3.3 To ensure that you have the correct URL for the Infoblox modules, open a Web browser and visit the URL you specified for the repository, in this example https://<ip_addr>/api/dist/CPAN. If the URL is correct, you can see a directory listing of the module files.

3.4 Save your CPAN configuration:

```
 cpan> o conf commit
commit: wrote '/usr/lib/perl5/5.8.8/CPAN/Config.pm'
```

4. (Optional) Reduce the number of CPAN fetch methods.

By reducing the number of CPAN fetch methods, you can shorten the installation process. For an explanation why Infoblox recommends this step, see the note in the introduction (before step 1).

```
 CPAN (and CPAN::Site) supports up to six different ways to search for and fetch files: curl, FTP, lynx,
ncftpget, wget, and LWP. Infoblox recommends that you choose the method that work best for you and only
configure those methods. For the typical cases, Infoblox recommends keeping LWP, FTP, and ncftpget enabled
and disabling curl, lynx and wget. To disable a fetch method, set it to an empty string and then commit the
configuration. In the example below, you first display the configuration parameters for curl, lynx, and
```

```
wget, and then set them to an empty string:

 cpan> o conf curl
 curl                           [/usr/bin/curl]

 cpan> o conf curl ""
 curl                           []

 cpan> o conf lynx
 lynx                           [/usr/bin/lynx]

 cpan> o conf lynx ""
 lynx                           []

 cpan> o conf wget
 wget                           [/usr/bin/wget]

 cpan> o conf wget ""
 wget                           []

 cpan> o conf commit
 commit: wrote '/usr/lib/perl5/5.8.8/CPAN/Config.pm'
```

5. Reload the CPAN::Site index.

Use CPAN to reload the CPAN::Site index:

```
 cpan> reload index
 CPAN: Storable loaded ok
 Going to read /root/.cpan/Metadata
 Database was generated on Sat, 09 Sep 2006 22:32:52 GMT
 CPAN: LWP::UserAgent loaded ok
 Fetching with LWP:
 https://<ip_addr>/api/dist/CPAN/authors/01mailrc.txt.gz
 ...
 Fetching with LWP:
 https://<ip_addr>/api/dist/CPAN/modules/03modlist.data.gz
 LWP failed with code[404] message[Not Found]
 Fetching with LWP:
 ftp://mirrors.kernel.org/pub/CPAN/modules/03modlist.data.gz
 Going to read /root/.cpan/sources/modules/03modlist.data.gz
 Going to write /root/.cpan/Metadata
```

Note: Unlike CPAN, CPAN::Site is designed so that some of the files that describe the available packages are not found in all of the locations in your URL list. It is normal to see some "file not found" errors during the index reload.

6. Install the Infoblox package on your management system.

The usual CPAN process for installing Perl modules is:

6.1 Search

6.2 Test

6.3 Install

6.4 Uninstall and Reinstall

6.1 Search

Use the m operator to search for the Infoblox module:

```
 cpan> m /Infoblox/
 CPAN: Storable loaded ok
 Going to read /root/.cpan/Metadata
 Database was generated on Mon, 18 Sep 2006 06:29:55 GMT
 CPAN: LWP::UserAgent loaded ok
 . . .
 Fetching with LWP:
 https://<ip_addr>/api/dist/CPAN/site/01mailrc.txt.gz
 Going to read /root/.cpan/sources/site/01mailrc.txt.gz
 Module id = Infoblox
 CPAN_USERID  INFOBLOX (Infoblox Technical Support <support@infoblox.com>)
 CPAN_VERSION 4.9999990014709
 CPAN_FILE    INFOBLOX/Infoblox-4.9999990014709.tar.gz
 INST_FILE    (not installed)
```

If the search cannot find the Infoblox modules:

a. Ensure that you are using CPAN::Site, not CPAN as shown in 2. Run CPAN::Site, instead of CPAN. b. Check the Infoblox appliance in the urllist as shown in step 3.3.

6.2 Test

You can optionally test the package before the installation:

```
cpan> test Infoblox
Running test for module Infoblox
Running make for Infoblox-4.999990014709.tar.gz
...
All tests successful.
Files=1, Tests=1,  0 wallclock secs ( 0.74 cusr +  0.08 csys =  0.82 CPU)
/usr/bin/make test - OK
```

6.3 Install

Install the Infoblox package:

```
cpan> install Infoblox
Running install for module Infoblox
Running make for INFOBLOX/Infoblox-4.9999990014709.tar.gz
...
Writing /usr/lib/perl5/site_perl/5.8.8/i386-linux-thread-multi/auto/Infoblox/.packlist
Appending installation info to /usr/lib/perl5/5.8.8/i386-linux-thread-multi/perllocal.pod
/usr/bin/make install  -- OK
```

To exit the CPAN::Site shell:

```
cpan> quit
```

The installation is complete.

6.4 Uninstalling and Reinstalling the Infoblox Package

Although not directly supported by CPAN, it is simple to uninstall the Infoblox package using published techniques. One way to do it is provided by the modrm program that is described in the ExtUtils::Packlist documentation. See http://search.cpan.org/~yves/ExtUtils-Install-1.41/lib/ExtUtils/Packlist.pm#EXAMPLE for the modrm program. To reinstall it, repeat steps 5 and 6 above.

Infoblox::CiscoISE::EAAssociation - A Cisco ISE extensible attributes association.

NAME

Infoblox::CiscoISE::EAAssociation - A Cisco ISE extensible attributes association.

DESCRIPTION

The Cisco ISE extensible attribute association provides information on NIOS extensible attributes mapping on Cisco ISE attributes.

CONSTRUCTOR

```
my $ea_assoc = Infoblox::CiscoISE::EAAssociation->new(
    name      => 'ACCOUNT_SESSION_ID' | 'AUDIT_SESSION_ID' |
                 'EPS_STATUS' | 'IP_ADDRESS' |'MAC' |'NAS_IP_ADDRESS' | 'NAS_PORT_ID' |
                 'POSTURE_STATUS' |'POSTURE_TIMESTAMP',                                  #Required
    mapped_ea => $string,                                                                #Required
```

SESSION METHODS

The object does not have any session methods.

MODULE METHODS

This section describes all the functions that you can apply to Cisco ISE extensible attributes association object.

Infoblox::CiscoISE::SubscribeSetting->mapped_ea_attributes( )

Use this method to set or retrieve the list of extensible attribute associations that are mapped to Cisco ISE attributes. See Infoblox::CiscoISE::SubscribeSetting->mapped_ea_attributes() for parameters and return values.

Example

```
#Get mapped_ea_attributes value
my $mapped_ea_attributes = $object->mapped_ea_attributes();

#Modify mapped_ea_attributes value
$object->mapped_ea_attributes([$ea_assoc1, $ea_assoc2]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Cisco ISE extensible attribute association object.

name( )

Use this method to set or retrieve the Cisco ISE attribute name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'ACCOUNT_SESSION_ID', 'AUDIT_SESSION_ID', 'EPS_STATUS', 'IP_ADDRESS', 'MAC', 'NAS_IP_ADDRESS', 'NAS_PORT_ID', 'POSTURE_STATUS' and 'POSTURE_TIMESTAMP',

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name value
my $name = $object->name();

#Modify name value
$object->name('EPS_STATUS');
```

mapped_ea( )

Use this method to set or retrieve the NIOS extensible attribute definition name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired extensible attribute definition name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mapped_ea value
my $mapped_ea = $object->mapped_ea();

#Modify mapped_ea value
$object->mapped_ea('nios_ead');
```

NAME

Infoblox::CiscoISE::Endpoint - A Cisco ISE endpoint object.

DESCRIPTION

The CiscoISE endpoint object provides configuration for third party Cisco ISE servers integration.

CONSTRUCTOR

```
 my $ise_endpoint = Infoblox::CiscoISE::Endpoint->new(
     address                  => $fqdn | $ipaddr,                                                  #
Required
     bulk_download_certificate => $path,                                                           #
Required
     client_certificate       => $path,                                                            #
Required
     subscribe_settings       => $subscribe_settings,                                              #
Required
     subscribing_member       => $string,                                                          #
Required
     version                  => 'VERSION_1_3' | 'VERSION_1_4' | 'VERSION_2_0',                    #
Required
     comment                  => $string,                                                          #
Optional / Default is undefined
     connection_timeout       => $uint,                                                            #
Optional / Default is 10
     disable                  => 'true' | 'false',                                                 #
Optional / Default is 'true'
     extattrs                 => { $string => $extattr, ... },                                     #
Optional / Default is undefined
     extensible_attributes    => {$string => $string | $num, $string => [ $string | $num, ... ], ... } #
```

```
Optional / Default is undefined
     network_view              => $string,                                    #
Optional / Default is 'default'
     publish_settings          => $publish_settings,                          #
Optional / Default is undefined
     secondary_address         => $fqdn | $ipaddr,                            #
Optional / Default is undefined
     type                      => 'TYPE_CISCO',                               #
Optional / Default is 'TYPE_CISCO',
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a Cisco ISE endpoint object.

Infoblox::Session->add( )

Use this method to add the object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $object = Infoblox::CiscoISE::Endpoint->new(
    address                   => '10.0.0.1',
    bulk_download_certificate => '/path/to/bulk_download_cert.pem',
    client_certificate        => '/path/to/client_cert.pem',
    subscribe_settings        => $subscribe_settings,
    subscribing_member        => 'infoblox.com',
    version                   => 'VERSION_1_3',
);

#Submit for addition
my $response = $session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Cisco ISE endpoint object:

 address                   - Optional. The FQDN or IP address of the Cisco ISE endpoint.
 comment                   - Optional. The Cisco ISE endpoint comment in string format
 extattrs                  - Optional. A hash reference containing Infoblox::Grid::Extattr object.
 extensible_attributes     - Optional. A hash reference containing extensible attributes.
 network_view              - Optional. The Cisco ISE endpoint network view name.
 resolved_address          - Optional. The resolved IP address of the Cisco ISE endpoint.
 resolved_secondary_address - Optional. The resolved secondary IP address of the Cisco ISE endpoint.
 secondary_address         - Optional. The secondary FQDN or IP address of the Cisco ISE endpoint.
 subscribing_member        - Optional. The Cisco ISE endpoint subscribing member name.
 type                      - Optional. The Cisco ISE endpoint type.
 version                   - Optional. The Cisco ISE endpoint version.
```

Examples

```
my @retrieved_objs = $session->get(
    object  => 'Infoblox::CiscoISE::Endpoint',
    address => '10.0.0.1',
);

my @retrieved_objs = $session->get(
    object               => 'Infoblox::CiscoISE::Endpoint',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

Infoblox::Session->modify( )

Use this method to modify the object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify comment value
$object->comment('this is a modified comment');

#Submit modification
```

```
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove the object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP range object, and then submit this object for removal.

Example

```
#Get the objects
my @retrieved_objs = $session->get(
    object       => 'Infoblox::CiscoISE::Endpoint',
    address      => '10.0.0.1',
    newtork_view => 'default',
);

#Find the desired object from the retrieved list
my $desired_object = $retrieved_objs[0];

#Submit for removal
my $response = $session->remove($desired_object);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for the Cisco ISE endpoint object:

 address                    - Optional. The FQDN or IP address of the Cisco ISE endpoint (regexp).
 comment                    - Optional. The Cisco ISE endpoint comment in string format (regexp).
 extattrs                   - Optional. A hash reference containing Infoblox::Grid::Extattr object.
 extensible_attributes      - Optional. A hash reference containing extensible attributes.
 network_view               - Optional. The Cisco ISE endpoint network view name (exact).
 resolved_address           - Optional. The resolved IP address of the Cisco ISE endpoint (regexp).
 resolved_secondary_address - Optional. The resolved secondary IP address of the Cisco ISE endpoint
(regexp).
 secondary_address          - Optional. The secondary FQDN or IP address of the Cisco ISE endpoint
(regexp).
 subscribing_member         - Optional. The Cisco ISE endpoint subscribing member name (exact).
 type                       - Optional. The Cisco ISE endpoint type (exact).
 version                    - Optional. The Cisco ISE endpoint version (exact).
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# search for objects
my @retrieved_objs = $session->search(
    object       => 'Infoblox::CiscoISE::Endpoint',
    network_view => 'default',
    address      => '10.*',
    comment      => '.*comment',
);

# search for objects defining 'Santa Clara' for 'Site' extensible attribute
my @retrieved_objs = $session->search(
    object               => 'Infoblox::DHCP::Range',
    extensible_attributes => {'Site' => 'Santa Clara'},
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Cisco ISE endpoint.

address( )

Use this method to set or retrieve the fully-qualified domain name (FQDN) or IP address of the Cisco ISE endpoint.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IP address or FQDN in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address value
my $address = $object->address();

#Modify address value
$object->address('foo.com');
```

bulk_download_certificate( )

Use this method to set the path to a bulk download certificate file. This is a write-only attribute.

Include the specified parameter to set the attribute value.

Parameter

The valid value is a path to a certificate in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify bulk_download_certificate value
$object->bulk_download_certificate('/path/to/cert.pem');
```

bulk_download_certificate_subject( )

Use this method to retrieve the bulk download certificate subject. This is a read-only attrbiute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get bulk_download_certificate_subject value
my $bulk_download_certificate_subject = $object->bulk_download_certificate_subject();
```

bulk_download_certificate_valid_from( )

Use this method to retrieve the time from which the bulk download certificate is valid. This is a read-only attrbiute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get bulk_download_certificate_valid_from value
my $bulk_download_certificate_valid_from = $object->bulk_download_certificate_valid_from();
```

bulk_download_certificate_valid_to( )

Use this method to retrieve the bulk download certificate expiration time. This is a read-only attrbiute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get bulk_download_certificate_valid_to value
my $bulk_download_certificate_valid_to = $object->bulk_download_certificate_valid_to();
```

client_certificate( )

Use this method to set the path to a client certificate file. This is a write-only attribute.

Include the specified parameter to set the attribute value.

Parameter

The valid value is a path to a certificate in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Modify client_certificate value
$object->client_certificate('/path/to/cert.pem');
```

client_certificate_subject( )

Use this method to retrieve the client certificate subject. This is a read-only attrbiute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get client_certificate_subject value
my $client_certificate_subject = $object->client_certificate_subject();
```

client_certificate_valid_from( )

Use this method to retrieve the time from which the client certificate is valid. This is a read-only attrbiute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get client_certificate_valid_from value
my $client_certificate_valid_from = $object->client_certificate_valid_from();
```

client_certificate_valid_to( )

Use this method to retrieve the bulk client certificate expiration time. This is a read-only attrbiute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get client_certificate_valid_to value
my $client_certificate_valid_to = $object->client_certificate_valid_to();
```

comment( )

Use this method to set or retrieve the Cisco ISE endpoint comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired comment in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment value
my $comment = $object->comment();

#Modify comment value
$object->comment('ise comment');
```

connection_status( )

Use this method to retrieve the Cisco ISE endpoint connection status. This is a read-only attrbiute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get connection_status value
my $connection_status = $object->connection_status();
```

connection_timeout( )

Use this method to set or retrieve the timeout value (in seconds) for the Cisco ISE endpoint connections.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer between 1 and 180. The default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get connection_timeout value
my $connection_timeout = $object->connection_timeout();

#Modify connection_timeout value
$object->connection_timeout('20');
```

disable( )

Use this method to set or retrieve the flag that indicates whether the Cisco ISE endpoint is enabled or disabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to disable the Cisco ISE endpoint or 'false' to enable it. The default value is 'true'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable value
my $disable = $object->disable();

#Modify disable value
$object->disable('false');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Cisco ISE endpoint object.

Parameter

Valid value is a hash reference that contains the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs value
my $extattrs = $object->extattrs();

#Modify extattrs value
$dhcp_range->extattrs({'Site' => $extattr1, 'Administrator' => $extattr2});
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a Cisco ISE endpoint object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes value
my $extensible_attributes = $object->extensible_attributes();
#Modify extensible attributes
$object->extensible_attributes({'Site' => 'Santa Clara', 'Administrator' => ['Peter', 'Tom']});
```

network_view( )

Use this method to set or retrieve the Cisco ISE endpoint network view name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired network view name in string format. The default value is 'default'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network_view value
my $network_view = $object->network_view();

#Modify network_view value
$object->network_view('internal');
```

publish_settings( )

Use this method to set or retrieve the Cisco ISE endpoint publish settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::CiscoISE::PublishSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get publish_settings value
my $publish_settings = $object->publish_settings();

#Modify publish_settings value
$object->publish_settings($publish_settings);
```

resolved_address( )

Use this method to retrieve the resolved IP address of the Cisco ISE endpoint. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get resolved_address value
my $resolved_address = $object->resolved_address();
```

resolved_secondary_address( )

Use this method to retrieve the resolved secondary IP address of the Cisco ISE endpoint. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get resolved_secondary_address value
my $resolved_secondary_address = $object->resolved_secondary_address();
```

secondary_address( )

Use this method to set or retrieve the secondary fully-qualified domain name (FQDN) or IP address of the Cisco ISE endpoint.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired IP address or FQDN in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get secondary_address value
my $secondary_address = $object->secondary_address();

#Modify secondary_address value
$object->secondary_address('foo.com');
```

subscribe_settings( )

Use this method to set or retrieve the Cisco ISE endpoint subscribe settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::CiscoISE::SubscribeSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscribe_settings value
my $subscribe_settings = $object->subscribe_settings();

#Modify subscribe_settings value
$object->subscribe_settings($subscribe_settings);
```

subscribing_member( )

Use this method to set or retrieve the Cisco ISE endpoint subscribing member host name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired subscribing member host name in string format. The default value is 'default'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscribing_member value
my $subscribing_member = $object->subscribing_member();

#Modify subscribing_member value
$object->subscribing_member('infoblox.com');
```

type( )

Use this method to set or retrieve the Cisco ISE endpoint type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is 'TYPE_CISCO'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get type value
my $type = $object->type();

#Modify type value
$object->type('TYPE_CISCO');
```

version( )

Use this method to set or retrieve the Cisco ISE endpoint version.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are 'VERSION_1_3', 'VERSION_1_4' and 'VERSION_2_0'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get version value
my $version = $object->version();

#Modify version value
$object->version('VERSION_2_0');
```

NAME

Infoblox::CiscoISE::PublishSetting - A Cisco ISE publish settings.

DESCRIPTION

The Cisco ISE publish setting contains a list of extensible attributes that are enabled for publishing to a Cisco ISE server.

CONSTRUCTOR

```
my $publish_setting = Infoblox::CiscoISE::PublishSetting->new(
    enabled_attributes => ['CLIENT_ID' | 'FINGERPRINT' | 'HOSTNAME' | 'IPADDRESS' |
                           'INFOBLOX_MEMBER' | 'LEASE_STATE' | 'LEASE_START_TIME' |
                           'LEASE_END_TIME' | 'MAC_OR_DUID' | 'NETBIOS_NAME', ...],
);
```

SESSION METHODS

The object does not have any session methods.

MODULE METHODS

This section describes all the functions that you can apply to Cisco ISE publish settings object.

Infoblox::CiscoISE::Endpoint->publish_settings( )

Use this method to set or retrieve the Cisco ISE endpoint publish settings. See Infoblox::CiscoISE::Endpoint->publish_settings() for parameters and return values.

Example

```
#Get publish_settings value
my $publish_settings = $object->publish_settings();

#Modify publish_settings value
$object->publish_settings($publish_settings);
```

Infoblox::Notification::Rule->publish_settings( )

Use this method to set or retrieve the notification rule publish settings. See Infoblox::Notification::Rule->publish_settings() for parameters and return values.

Example

```
#Get publish_settings value
my $publish_settings = $object->publish_settings();

#Modify publish_settings value
$object->publish_settings($publish_settings);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Cisco ISE publish settings.

enabled_attributes( )

Use this method to set or retrieve the list of extensible attributes that are enabled for publishing to a Cisco ISE server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array that contains following values: 'CLIENT_ID', 'FINGERPRINT', 'HOSTNAME', 'IPADDRESS', 'INFOBLOX_MEMBER', 'LEASE_STATE', 'LEASE_START_TIME', 'LEASE_END_TIME', 'MAC_OR_DUID', 'NETBIOS_NAME'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enabled_attributes value
my $enabled_attributes = $object->enabled_attributes();

#Modify enabled_attributes value
$object->enabled_attributes(['CLIENT_ID', 'IPADDRESS']);
```

NAME

Infoblox::CiscoISE::PublishSetting - A Cisco ISE subscribe settings.

DESCRIPTION

The Cisco ISE subscribe setting contains list of extensible attributes that are enabled for subscription from Cisco ISE server.

CONSTRUCTOR

```
 my $subscribe_setting = Infoblox::CiscoISE::PublishSetting->new(
     enabled_attributes   => ['DOMAINNAME' | 'ENDPOINT_PROFILE' | 'SECURITY_GROUP' | 'SESSION_STATE' |
'SSID' | 'USERNAME' | 'VLAN', ...], #Required
     mapped_ea_attributes => [$ea_assoc1, $ea_assoc2, ...],
#Optional / Default is undefined
 );
```

SESSION METHODS

The object does not have any session methods.

MODULE METHODS

This section describes all the functions that you can apply to Cisco ISE subscribe settings object.

Infoblox::CiscoISE::Endpoint->subscribe_settings( )

Use this method to set or retrieve the Cisco ISE endpoint subscribe settings. See Infoblox::CiscoISE::Endpoint->subscribe_settings() for parameters and return values.

Example

```
#Get subscribe_settings value
my $subscribe_settings = $object->subscribe_settings();

#Modify subscribe_settings value
$object->subscribe_settings($subscribe_settings);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Cisco ISE subscribe settings.

enabled_attributes( )

Use this method to set or retrieve the list of attributes that are enabled for subscription from the Cisco ISE server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array that contains following values: 'DOMAINNAME', 'ENDPOINT_PROFILE', 'SECURITY_GROUP', 'SESSION_STATE', 'SSID', 'USERNAME', 'VLAN'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enabled_attributes value
my $enabled_attributes = $object->enabled_attributes();

#Modify enabled_attributes value
$object->enabled_attributes(['DOMAINNAME', 'SECURITY_GROUP']);
```

mapped_ea_attributes( )

Use this method to set or retrieve the list of extensible attribute associations that are mapped to Cisco ISE attributes.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of Infoblox::CiscoISE::EAAssociation objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mapped_ea_attributes value
my $mapped_ea_attributes = $object->mapped_ea_attributes();

#Modify mapped_ea_attributes value
$object->mapped_ea_attributes([$ea_assoc1, $ea_assoc2]);
```

Infoblox::Cursor - Manages paged searches.

- NAME
- DESCRIPTION
- CONSTRUCTOR
- METHODS
  - fetch_size( )
  - other parameters
  - Supported object types
- SAMPLE CODE
- AUTHOR
- SEE ALSO
- COPYRIGHT

NAME

Infoblox::Cursor - Manages paged searches.

DESCRIPTION

This class enables users to conduct database searches returning large datasets in an object-by-object manner.

CONSTRUCTOR

```
my $cursor=$session->new_cursor(
                                fetch_size     => 200,
                                object         => "Infoblox::DNS::AllRecords",
                                return_methods => ['name'],
                                name           => ".*"
                               );
```

METHODS

This section describes all the methods that you can use when creating a cursor used for paged searches.

fetch_size( )

This method is used to set the amount of records returned from the back-end to the client for every request. Larger values will cause less requests to be sent to the back-end and more memory used on the client-side; smaller values will cause more requests.

The default value is 100.

other parameters

Other parameters for this constructor are any valid search parameters as described in Infoblox::Session->search()

Supported object types

Paged search is supported for the following object types:

Infoblox::DNS::AllRecords
Infoblox::DNS::Zone
Infoblox::DHCP::FixedAddr
Infoblox::DHCP::Network
Infoblox::DNS::Host
Infoblox::DNS::Record::A
Infoblox::DNS::Record::AAAA
Infoblox::DNS::Record::PTR
Infoblox::DNS::Record::TXT
Infoblox::DNS::Record::MX
Infoblox::DNS::Record::SRV
Infoblox::DNS::Record::CNAME
Infoblox::DNS::Record::DNAME

SAMPLE CODE

The following sample code demonstrates how to execute a paged search.

```
#PROGRAM STARTS: Include all the modules that will be used
```

```
$cursor=$session->new_cursor(
                             fetch_size => 100,
                             object => "Infoblox::DNS::AllRecords",
                             name   => '.*',
                            );

while ($current_record = $cursor->fetch()) {
    # $current_record will contain a matching record object
}
```

NAME

Infoblox::DHCP::DDNS - DHCP DDNS object.

DESCRIPTION

The object is used to configure Multi-Grid Master preferences for updates from DHCP to Multi-Grid Master zones.

CONSTRUCTOR

```
my $ddns = Infoblox::DHCP::DDNS->new(
    dns_ext_zone      => $string,           # required if zone_match is 'EXTERNAL'
    dns_grid_zone     => $string,           # required if zone_match is 'GRID'
    view              => $string,           # optional / The default value is the name of the default view
    external_primary  => $ipaddr,           # required if zone_match is 'EXTERNAL' or 'ANY_EXTERNAL'
    grid_primary      => $string,           # required if zone_match is 'GRID' or 'ANY_GRID'
    zone_match        => 'ANY_EXTERNAL' | 'ANY_GRID' | 'EXTERNAL' | 'GRID',  # required
);
```

SESSION METHODS

The object doesn't support any session methods.

METHODS

This section describes all the methods that you can use to configure and retrieve a DHCP DDNS object.

dns_ext_zone( )

Use this method to set or retrieve a zone name, in FQDN (Fully Qualified Domain Name) format, that is contained in an external member.

Parameter

A zone name in FQDN format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $value = $ddns->dns_ext_zone();
# Modify the attribute value
$ddns->dns_ext_zone('exmmdns.com');
```

dns_grid_zone( )

Use this method to set or retrieve a zone name, in FQDN (Fully Qualified Domain Name) format, that is contained in a Grid member.

Parameter

A zone name in FQDN format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $value = $ddns->dns_grid_zone();
# Modify the attribute value
$ddns->dns_grid_zone('mmdns.com');
```

view( )

Use this method to set or retrieve the name of the DNS view in which the zone is located.

Parameter

The name of the DNS view in string format. The default value is the name of the default view.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $value = $ddns->view();
# Modify the attribute value
$ddns->view('dnsview');
```

external_primary( )

Use this method to set or retrieve the IP address of an external member.

Parameter

The IP address of an external member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $value = $ddns->external_primary();
# Modify the attribute value
$ddns->external_primary('10.0.0.1');
```

grid_primary( )

Use this method to set or retrieve the name of the primary Grid member.

Parameter

The name of the primary Grid member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $value = $ddns->grid_primary();
# Modify the attribute value
$ddns->grid_primary('grid.com');
```

zone_match( )

Use this method to set or retrieve the matching type.

Parameter

The valid value is 'ANY_EXTERNAL', 'ANY_GRID', 'EXTERNAL' or 'GRID'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $value = $ddns->zone_match();
# Modify the attribute value
$ddns->zone_match('GRID');
```

NAME

Infoblox::DHCP::ExclusionRange - DHCP ExclusionRange object.

DESCRIPTION

The DHCP exclusion range describes the range of IP addresses that can be excluded in an address range. If static addresses are assigned to certain hosts in the middle of an address range, those addresses can be excluded from the address range so the DHCP server does not assign those IP addresses to clients.

CONSTRUCTOR

```
my $exclusion_range = Infoblox::DHCP::ExclusionRange->new(
      end_address   => $ipv4addr,      #Required
      start_address => $ipv4addr,      #Required
      comment       => $string,        #Optional / Default is empty
);
```

MODULE METHODS

The following functions are available to apply to a DHCP exclusion range object.

Infoblox::DHCP::Range->exclude( )

Use this function to specify exclusion range for the DHCP range. See Infoblox::DHCP::Range->exclude() for parameters and return values.

Example

```
#Construct a DHCP ExclusionRange object
my $exclusion_range = Infoblox::DHCP::ExclusionRange->new(
         end_address   => "10.0.0.8",
         start_address => "10.0.0.5",
         comment       => "Exclude four IP addresses"
);

# Configure DHCP ExclusionRange on the DHCP Range object
my $response = $dhcp_range->exclude([$exclusion_range]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP exclusion range object.

comment( )

Use this method to set or retrieve a descriptive comment of a DHCP exclusion range object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $exclusion_range->comment();
#Modify comment
$exclusion_range->comment("Modifying the DHCP exclusion range comment");
```

end_address( )

Use this method to set or retrieve the end address of a DHCP exclusion range object.

An end address is the last IP address in the DHCP exclusion range which is not available for the clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the end address of the DHCP exclusion range in IPv4 address format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get end_address
my $end_address = $exclusion_range->end_address();
#Modify end_address
$exclusion_range->end_address("10.0.0.9");
```

start_address( )

Use this method to set or retrieve the start address of a DHCP exclusion range object.

A start address is the first IP address in the DHCP exclusion range which is not available for the clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the start address of the DHCP exclusion range in IPv4 address format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get start_address
my $start_address = $exclusion_range->start_address();
#Modify start_address
$exclusion_range->start_address("10.0.0.6");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP exclusion range object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP exclusion range object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
              master   => "192.168.1.2", #appliance host ip
                                         #appliance user login
```

```
                username => "admin",
                password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create the Network object
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/8",
    comment => "add network",
);
unless($network) {
       die("Construct Network object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network object created successfully\n";

#Add the Network object into the Infoblox appliance through a session
$session->add($network)
    or die("Add Network object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "Network object added to Infoblox appliance successfully\n";

#Create the DHCP Range object
my $dhcp_range = Infoblox::DHCP::Range->new(
        end_addr   => "10.0.0.10",
        network    => "10.0.0.0/8",
        start_addr => "10.0.0.1",
);
unless($dhcp_range) {
       die("Construct DHCP Range object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Range object created successfully\n";

#Add the DHCP Range object into the Infoblox appliance through a session
$session->add($dhcp_range)
    or die("Add DHCP Range object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Range object added to Infoblox appliance successfully\n";
```

#Create a DHCP exclusion range object

```
my $exclusion_range = Infoblox::DHCP::ExclusionRange->new(
         end_address   => "10.0.0.8",
         start_address => "10.0.0.5",
         comment       => "Exclude four IP addresses"
);
unless($exclusion_range) {
       die("Construct DHCP exclusion range object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP exclusion range object created successfully\n";
```

#Add DHCP exclusion range to DHCP Range

```
#Get the DHCP Range object
my @retrieved_objs = $session->get(
    object     => "Infoblox::DHCP::Range",
    start_addr => "10.0.0.1"
);
my $object = $retrieved_objs[0];
unless ($object) {
       die("Get DHCP Range object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get DHCP Range object found at least 1 matching entry\n";

#Apply the changes to the DHCP Range object
$object->exclude([$exclusion_range]);

#Submit the changes to the Session
$session->modify($object)
    or die("Adding DHCP exclusion range to DHCP Range object failed: ",
```

```
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Range with exclusion range updated to Infoblox appliance successfully\n";
```

#Modify DHCP exclusion range

```
#Modifying the end address of the DHCP exclusion range object.
$exclusion_range->end_address("10.0.0.9");

#Modifying the start address of the DHCP exclusion range object.
$exclusion_range->start_address("10.0.0.6");

#Modifying the comment of the DHCP exclusion range object.
$exclusion_range->comment("Modified DHCP Exclusion Range");

#Apply changes to the DHCP Range object.
$object->exclude([$exclusion_range]);

#Update DHCP Range object through the Infoblox session.
$session->modify($object)
  or die("Modify DHCP Range object failed: ",
  $session->status_code() . ":" . $session->status_detail());
print "DHCP Range object with modified DHCP exclusion range updated to Infoblox appliance successfully\n";
```

#Remove DHCP exclusion range

```
#Remove the exclusion range from the DHCP Range object.
$object->exclude([]);

#Update DHCP Range object through the Infoblox session.
$session->modify($object)
  or die("Modify DHCP Range object failed: ",
  $session->status_code() . ":" . $session->status_detail());
print "Removed DHCP exclusion range from DHCP Range successfully\n";
```

NAME

Infoblox::DHCP::ExclusionRangeTemplate - DHCP ExclusionRangeTemplate object.

DESCRIPTION

The DHCP exclusion range template describes the range of IP addresses that can be excluded in an address range template. If static IP addresses are assigned to certain hosts in the middle of an address range, those addresses can be excluded from the address range so the DHCP server does not assign those IP addresses to the clients.

CONSTRUCTOR

```
my $exclusion_range_template = Infoblox::DHCP::ExclusionRangeTemplate->new(
      offset               => $num,          #Required
      number_of_addresses  => $num,          #Required
      comment              => $string,       #Optional / Default is empty
);
```

MODULE METHODS

The following functions are available to be applied to a DHCP exclusion range template object.

Infoblox::DHCP::RangeTemplate->exclude( )

Use this function to specify exclusion range for the DHCP range template object. See Infoblox::DHCP::RangeTemplate->exclude() for parameters and return values.

Example

```
#Construct a DHCP ExclusionRangeTemplate object
my $exclusion_range_template = Infoblox::DHCP::ExclusionRangeTemplate->new(
        offset               => "10",
        number_of_addresses  => "5",
        comment              => "Exclude five IP addresses"
);

# Configure DHCP ExclusionRangeTemplate on the DHCP Range template object
my $response = $dhcp_range_template->exclude([$exclusion_range_template]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP exclusion range template object.

comment( )

Use this method to set or retrieve a descriptive comment of a DHCP exclusion range template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $exclusion_range_template->comment();
#Modify comment
$exclusion_range_template->comment("Modifying the DHCP exclusion range template comment");
```

number_of_addresses( )

Use this method to set or retrieve the number of addresses in the DHCP exclusion range template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of addresses in this exclusion range template.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get number_of_addresses
my $number_of_addresses = $exclusion_range_template->number_of_addresses();
#Modify number_of_addresses
$exclusion_range_template->number_of_addresses("10");
```

offset( )

Use this method to set or retrieve the address offset of the DHCP exclusion range template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The address offset of this exclusion range template. The offset is calculated from the start address of network template to which the DHCP range template is assigned to. For example, if offset is set to 10 and number_of_addresses is set to 10, and network is set to 10.0.0.0/8, then start address of exclusion range created from this exclusion range template will be 10.0.0.10 and end address will be 10.0.0.20.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get offset
my $offset = $exclusion_range_template->offset();
#Modify offset
$exclusion_range_template->offset("10");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP exclusion range object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#PROGRAM STARTS: Include all the modules that will be used

```
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
              master   => "192.168.1.2", #appliance host ip
              username => "admin",       #appliance user login
              password => "infoblox"     #appliance password
```

```
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create the DHCP Range template object

```
my $dhcp_range_template = Infoblox::DHCP::RangeTemplate->new(
        name                    => "custom_range_template",
        offset                  => "10",
        number_of_addresses     => "10",
        authority               => "TRUE",
        bootfile                => "bootfile1.com",
);
unless($dhcp_range_template) {
       die("Construct DHCP Range template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Range template object created successfully\n";

#Add the DHCP Range object into the Infoblox appliance through a session
$session->add($dhcp_range_template)
    or die("Add DHCP Range template object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Range object added to Infoblox appliance successfully\n";
```

#Create a DHCP exclusion range templat object

```
my $exclusion_range_template = Infoblox::DHCP::ExclusionRangeTemplate->new(
         offset              => "10",
         number_of_addresses => "5",
         comment             => "Exclude five IP addresses"
);
unless($exclusion_range_template) {
       die("Construct DHCP exclusion range template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP exclusion range template object created successfully\n";
```

#Add DHCP exclusion range template to DHCP Range template

```
#Get the DHCP Range template object
my @retrieved_objs = $session->get(
    object     => "Infoblox::DHCP::RangeTemplate",
    name       => "custom_range_template"
);
my $object = $retrieved_objs[0];
unless ($object) {
       die("Get DHCP Range template object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get DHCP Range template object found at least 1 matching entry\n";

#Apply the changes to the DHCP Range template object
$object->exclude([$exclusion_range_template]);

#Submit the changes to the Session
$session->modify($object)
    or die("Adding DHCP exclusion range to DHCP Range template object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Range template with exclusion range template updated to Infoblox appliance successfully\n";
```

#Remove DHCP exclusion range template

```
#Remove the exclusion range template from the DHCP Range template object.
$object->exclude([]);

#Update DHCP Range template object through the Infoblox session.
$session->modify($object)
  or die("Modify DHCP Range template object failed: ",
  $session->status_code() . ":" . $session->status_detail());
print "Removed DHCP exclusion range template from DHCP Range successfully\n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::ExpandNetwork - Join or Expand an existing network

---

DESCRIPTION

Expanding/Joining multiple networks into a larger network is the opposite of spliting a network. You can select a network and expand it into a larger network with smaller netmask.

CONSTRUCTOR

```
#Constructor a DHCP Expand Network object
my $expand_network = Infoblox::DHCP::ExpandNetwork->new (
       network                => $Network|$IPv6Network, #Required
       prefix                 => $num,                 #Required
       auto_create_reversezone => "true" | "false",      #Optional / Default is "false"
       option_delete_ea        => "RETAIN" | "REMOVE",   #Optional / Default is "REMOVE"
    );
```

SESSION METHODS

This section describes all the methods in Infoblox::Session that you can apply to a DHCP ExpandNetwork object.

Infoblox::Session->add( )

Use this method to expand an existing network on the Infoblox appliance. See Infoblox::Session->`add()` for parameters and return values

Example

```
# construct the network to be expanded
my $network = Infoblox::DHCP::Network->new(
         network => "123.0.0.0/16",
           );

# construct a Expand Network object
my $expand_network = Infoblox::DHCP::ExpandNetwork->new (
        network                => $network,
        prefix                 => "13",
        auto_create_reversezone => "false"
);

# Submit the Expand network operation.
$session->add($expand_network);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute value of a Expand Network.

auto_create_reversezone( )

Use this method to set the auto_create_reversezone flag. When set, this flag will automatically create reverse-mapping zones for the

subnet.

Include the specified parameter to set the attribute value.

Parameter

Specify "true" to set auto_create_reversezone flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set auto_create_reversezone
$split_network->auto_create_reversezone("true");
```

network( )

Use this method to specify the network to be expanded.

Include the specified parameter to set the attribute value.

Parameter

The valid values are either Infoblox::DHCP::Network or Infoblox::DHCP::IPv6Network objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Specify network
my $network = Infoblox::DHCP::Network->new(
                    network => "123.0.0.0/16",
                    );
$expand_network->network($network);

#Specify IPv6 network
my $network = Infoblox::DHCP::IPv6Network->new(
                    network => "12::/68",
                    );
$expand_network->network($network);
```

option_delete_ea( )

Use this method to specify the action for inheritable extensible attributes that exist on descendants if a parent network is deleted.

Parameter

Valid value is "RETAIN" or "REMOVE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Specify option_delete_ea
$expand_network->option_delete_ea('RETAIN');
```

prefix( )

Use this method to specify the appropriate subnet mask to be expanded on the network.

Include the specified parameter to set the attribute value.

Parameter

Number with the subnet mask value. This value must be 1 smaller then the subnet mask of the network to be expanded. The minimuim value is 8.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Specify prefix
$expand_network->prefix(13);
```

SAMPLE CODE

The following sample code demonstrates different operations that can be applied to an object such as create, modify, and remove an object. This sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create network prior to splitting the network my $network = Infoblox::DHCP::Network->new(network => "123.0.0.0/16", comment => "add network",); unless($network){ die("Construct network object fail: ", Infoblox::status_code(). ":" .Infoblox::status_detail()); }

```
print"Network object created successfully.\n";

#Verify if the network exists
my $object = $session->get(
               object  => "Infoblox::DHCP::Network",
               network => "123.0.0.0/16"
               );
unless($object){
       print"Network does not exist on server, safe to add the network.\n";
       $session->add($network)
               or die("Add network failed: ",
                       $session->status_code(). ":" .$session->status_detail());
       }

print"Network added successfully.\n";
```

#Expand the network

```
my $expand_network = Infoblox::DHCP::ExpandNetwork->new (
                        network                => $network,
                        prefix                 => "13",
                        auto_create_reversezone => "false",
                      );
unless($expand_network){
       die("Construct expand network object fail: ",
               Infoblox::status_code(). ":" .Infoblox::status_detail());
       }

print"Expand network object created successfully.\n";

#Expand the network
$session->add( $expand_network )
         or die("Expand network fail:",
                     $session->status_code(). ":" .$session->status_detail());

print "Expand network successfully.\n";

NAME

Infoblox::DHCP::FailOver - DHCP Failover object.

DESCRIPTION

DHCP failover is a protocol designed to allow a backup DHCP server to take over for a main server if the main server is taken off the network for any reason. DHCP failover can be used to configure two DHCP servers to operate as a redundant pair.

CONSTRUCTOR

```
 my $dhcp_failover = Infoblox::DHCP::FailOver->new(
     name                   => $string,                              #Required
     primary                => $ipv4addr | $Member                   #Required
     secondary              => $ipv4addr | $Member                   #Required
     comment                => $string,                              #Optional / Default is empty
     extattrs               => { $string => $extattr, ... },         #Optional / Default is undefined
     extensible_attributes  => { $string => $string | $num, $string => [ $string | $num, ... ], ... },
#Optional / Default is undefined
     load_balance_split     => $num,                                 #Optional / Default value is 128
     max_load_balance_delay => $num,                                 #Optional / Default value is 3
     max_client_lead_time   => $num,                                 #Optional / Default value is 3600
     max_unacked_updates    => $num,                                 #Optional / Default value is 10
     max_response_delay     => $num,                                 #Optional / Default value is 60
     recycle_leases         => "true" | "false" | undef,             #Optional / Default value is undefined
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that can be applied to a DHCP failover object.

Infoblox::Session->add( )

Use this method to add a DHCP failover object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Create a DHCP Member object
my $memberdhcp = Infoblox::DHCP::Member->new(
      name     => "infoblox.localdomain",
      ipv4addr => "192.168.1.2"
);

#Construct an object
my $dhcp_failover = Infoblox::DHCP::FailOver->new(
    name                  => "peer1",
    primary               => $memberdhcp,
    secondary             => "1.1.1.1",
    load_balance_split    => 128,
    max_load_balance_delay => 3,
    max_client_lead_time  => 3600,
    max_unacked_updates   => 10,
    max_response_delay    => 60,
    recycle_leases        => "false",
);

# Submit for addition
my $response = $session->add( $dhcp_failover );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching DHCP failover objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP failover object:

name - Required. Name of a DHCP failover in string format.
extattrs     - Optional. A hash reference containing extensible attributes.
```

Example

```
my @retrieved_objs = $session->get(
                     object     => "Infoblox::DHCP::FailOver",
                     name       => "peer1" );
```

Infoblox::Session->modify( )

Use this method to modify a DHCP failover object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use method to modify the load_balance_split.
$dhcp_failover->load_balance_split(130);
# Submit modification
my $response = $session->modify( $dhcp_failover );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP failover object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP failover object, and then submit this object for removal.

Example

```
# Get the objects with the same name
my @retrieved objs   $session  get
```

```
                    =         ->    (
    object  => "Infoblox::DHCP::FailOver",
    name    => "peer1" );
# Find the desired object from the retrieved list.
my $desired_dhcp_failover = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_dhcp_failover );
```

Infoblox::Session->search( )

Use this method to search for DHCP failover objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

Apply the following attributes, to search for a DHCP failover object:

```
name    - Optional. The name of a DHCP failover object. Regular expression supported.
comment - Optional. The comment of the DHCP failover object. Regular expression supported.
extattrs      - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for DHCP failover object with name as peer1
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::FailOver",
    name    => "pe.*" );

# search all DHCP failover associations with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
   object => "Infoblox::DHCP::FailOver",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP failover object.

association_type( )

Use this method to retrieve the value indicating whether the failover assocation is Microsoft or Grid based. This is a read-only attribute.

Parameter

None

Returns

The return value can be "MS" or "GRID".

Example

```
#Get association type
my $association_type = $failover->association_type();
```

ms_association_mode( )

Use this method to retrieve the value that indicates whether the failover association is read-write or read-only. This is a read-only attribute.

Parameter

None

Returns

The valid return values are "RO" and "RW".

Example

```
#Get association_mode
my $association_mode = $failover->ms_association_mode();
```

ms_enable_authentication( )

Use this method to enable or disable authentication for the failover association.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable authentication for the failover association or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ms_enable_authentication value
my $enable_authentication_value = $failover->ms_enable_authentication();
#Modify ms_enable_authentication value
$failover->ms_enable_authentication("true");
```

ms_enable_switchover_interval( )

Use this method to enable or disable the switchover interval.

The ms_enable_switchover_interval attribute can be specified explicitly. It is also set implicitly when ms_switchover_interval is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the switchover interval or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ms_enable_switchover_interval value
my $enable_switchover_interval = $failover->ms_enable_switchover_interval();
#Modify ms_enable_switchover_interval value
$failover->ms_enable_switchover_interval("true");
```

ms_failover_mode( )

Use this method to set or retrieve the mode for the failover association.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid parameters are "LOADBALANCE" and "HOTSTANDBY".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

```
=item B<Example>

#Get ms_failover_mode
my $failover_mode = $failover->ms_failover_mode();
#Modify ms_failover_mode
$failover->ms_failover_mode("HOTSTANDBY");
```

ms_failover_partner( )

Use this method to set or retrieve the failover partner defined in the association for the Microsoft Server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that the failover partner must be retrieved from the server settings and cannot be changed after being written.

Parameter

The valid parameter is an Infoblox::Grid::MSServer object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ms_failover_partner
my $failover_partner = $failover->ms_failover_partner();
#Modify ms_failover_partner
$failover->ms_failover_partner($failover_partner);
```

ms_hotstandby_partner_role( )

Use this method to set or retrieve the partner role in the case of HotStandby.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid values are "ACTIVE" and "PASSIVE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ms_hotstandby_partner_role
my $partner_role = $failover->ms_hotstandby_partner_role();
#Modify ms_hotstandby_partner_role
$failover->ms_hotstandby_partner_role("ACTIVE");

=back
```

ms_is_conflict( )

Use this method to retrieve the flag used to indicate whether the matching Microsfot failover association (if any) is in synchronization (False) or not (True). The method returns False if there is no matching failover association. This is a read-only attribute.

Parameter

None

Returns

The valid return values are "true" and "false".

Example

```
#Get ms_is_conflict value
my $is_conflict = $failover->ms_is_conflict();
```

ms_server( )

Use this method to set or retrieve the primary Microsoft Server object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that the Microsoft server must be retrieved from the server settings and cannot be changed after being written.

Parameter

The valid parameter is an Infoblox::Grid::MSServer object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ms_server
my $server = $failover->ms_server();
#Modify ms_failover_partner
$failover->ms_server($server);
```

ms_shared_secret( )

Use this method to set the shared secret for the failover association authentication. This is a write-only attribute.

Parameter

The valid value is a string that contains the shared secret for the failover association authentication.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set ms_shared_secret value
$failover->ms_shared_secret($shared_secret);
```

ms_state( )

Use this method to retrieve the failover association state. This is a read-only attribute.

Parameter

None

Returns

The valid return values are "NO_STATE", "INIT", "STARTUP", "NORMAL", "COMMUNICATION_INIT", "PARTNER_DOWN", "POTENTIAL_CONFLICT", "CONFLICT_DONE", "RESOLUTION_INIT", "RECOVER", "RECOVER_DONE", "RECOVER_WAIT".

Example

```
#Get ms_state value
my $state = $failover->ms_state();
```

ms_switchover_interval( )

Use this method to set or retrieve the time (in seconds) that DHCPv4 server will wait before transitioning the server from the COMMUNICATION-INT state to PARTNER-DOWN state.

Setting this method to a defined value implicitly sets the ms_enable_switchover_interval method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the ms_enable_switchover_interval method to "false".

Note that when ms_switchover_interval is set to a defined value and ms_enable_switchover_interval is set to "false", the last operation takes precedence. Thus the sequence $object->ms_switchover_interval(20); $object->ms_enable_switchover_interval("false"); will set ms_enable_switchover_interval to "false", and the sequence $object->ms_enable_switchover_interval("false"); $object->ms_switchover_interval(20); will result in ms_enable_switchover_interval="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value are integers between 1 and 65535.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ms_switchover_interval value
my $so_interval = $failover->ms_switchover_interval();
#Modify ms_switchover_interval value
$failover->ms_switchover_interval(1000);
```

ms_previous_state( )

Use this method to retrieve the previous failover association state. This is a read-only attribute.

Parameter

None

Returns

The valid return values are "NO_STATE", "INIT", "STARTUP", "NORMAL", "COMMUNICATION_INIT", "PARTNER_DOWN", "POTENTIAL_CONFLICT", "CONFLICT_DONE", "RESOLUTION_INIT", "RECOVER", "RECOVER_DONE", "RECOVER_WAIT".

Example

```
#Get ms_previous_state value
my $previous_state = $failover->ms_previous_state();
```

name( )

Use this method to set or retrieve the name of a DHCP failover object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $dhcp_failover->name();
#Modify name
$dhcp_failover->name("peer2");
```

primary( )

Use this method to set or retrieve primary server of a DHCP failover object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify external primary server in IPv4 address format or grid primary server in a defined Infoblox::DHCP::Member object. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get primary
my $primary = $dhcp_failover->primary();
#Modify primary
$dhcp_failover->primary($member); #$member is a Infoblox::DHCP::Member object
```

secondary( )

Use this method to set or retrieve secondary server of a DHCP failover object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify external secondary server in IPv4 address format or grid secondary server in a defined Infoblox::DHCP::Member object. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get secondary
my $secondary = $dhcp_failover->secondary();
#Modify secondary
$dhcp_failover->secondary("2.2.2.2");
```

comment( )

Use this method to set or retrieve a descriptive comment about a DHCP failover object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $dhcp_failover->comment();
# Modify comment
$dhcp_failover->comment("add a network");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP failover object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $dhcp_failover->extattrs();
#Modify extattrs
$dhcp_failover->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP failover object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $dhcp_failover->extensible_attributes();
#Modify extensible attributes
$dhcp_failover->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom'
] });
```

load_balance_split( )

Use this method to set or retrieve a load balancing split value of a DHCP failover object.

Load balancing split determines which server handles IP address requests. This parameter is specified on the primary only.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the value of the maximum load balancing delay in a 8-bit integer format (range from 0 to 255). The default value is 128.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get load_balance_split
my $load_balance_split = $dhcp_failover->load_balance_split();
#Modify load_balance_split
$dhcp_failover->load_balance_split(200);
```

max_load_balance_delay( )

Use this method to set or retrieve the maximum load balancing delay value of a DHCP failover object.

Maximum load balancing delay specifies the cutoff after which load balancing is disabled. The cutoff is based on the number of seconds since the client sent its first DHCPDISCOVER or DHCPREQUEST message. For instance, if one of the failover peers gets into a state where it is responding to failover messages, but not responding to some client requests, the other failover peer will take over its client load automatically as the clients retry.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the value of the maximum load balancing delay in a 32-bit integer format (range from 0 to 4294967295) that represents the duration in seconds. The default value is 3.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_load_balance_delay
my $max_load_balance_delay = $dhcp_failover->max_load_balance_delay();
#Modify max_load_balance_delay
$dhcp_failover->max_load_balance_delay("500");
```

max_client_lead_time( )

Use this method to set or retrieve the maximum client lead time value of a DHCP failover object.

Maximum client lead time value specifies the length of time that a failover peer can renew a lease without contacting the other peer. The larger the number, the longer it takes for the peer server to recover IP addresses after moving to the Partner Down mode. The smaller the number, the more load your servers experience when they are not communicating. This is specified on the primary server only.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the value of the maximum client lead time in a 32-bit integer format (range from 0 to 4294967295) that represents the duration in seconds. The default value is 3600.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_client_lead_time
my $max_client_lead_time = $dhcp_failover->max_client_lead_time();
```

```
#Modify max_client_lead_time
$dhcp_failover->max_client_lead_time(600);
```

max_unacked_updates( )

Use this method to set or retrieve the maximum number of unacked updates value of a DHCP failover object.

Maximum number of unacked updates value specifies how many update messages the server can send before it should receive an ACK from the failover peer. If no ACK is received after these messages are sent, failover occurs.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the value of the maximum number of unacked updates in a 32-bit integer format (range from 0 to 4294967295) that represents the number of messages. The default value is 10.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_unacked_updates
my $max_unacked_updates = $dhcp_failover->max_unacked_updates();
#Modify max_unacked_updates
$dhcp_failover->max_unacked_updates(700);
```

max_response_delay( )

Use this method to set or retrieve the maximum response delay value of a DHCP failover object.

Maximum response delay value before failover specifies how many seconds can transpire before the primary server assumes its peer (the secondary server) is not sending messages due to failure.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the value of the maximum response delay in a 32-bit integer format (range from 0 to 4294967295) that represents the duration in seconds. The default value is 60.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get max_response_delay
my $max_response_delay = $dhcp_failover->max_response_delay();
#Modify max_response_delay
$dhcp_failover->max_response_delay(800);
```

primary_state( )

Use this method to retrieve the primary server status of a DHCP failover object.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get primary_state
my $primary_state = $dhcp_failover->primary_state();
```

recycle_leases( )

Use this method to set or retrieve the recycle leases flag of a DHCP failover object.

If the flag is enabled, the leases are kept in recycle bin until one week after expiration and when the flag is disabled, the leases are irrecoverably deleted.

Parameter

Specify "true" to set the recycle_leases flag or "false" to deactivate/unset it. The default value for this field is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $dhcp_failover->recycle_leases();
#Modify recycle_leases
$dhcp_failover->recycle_leases("true");
#Un-override recycle_leases
$dhcp_failover->recycle_leases(undef);
```

secondary_state( )

Use this method to retrieve the secondary server status of a DHCP failover object.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get secondary_state
my $secondary_state = $dhcp_failover->secondary_state();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP failover object such as add, search, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP failover object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a DHCP Member object
my $memberdhcp = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2"
);
unless($memberdhcp) {
       die("Construct member failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Member object created successfully\n";

#Create the Network object with member
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/8",
    comment => "add network",
```

```
    members => [ $memberdhcp ]

NAME

Infoblox::DHCP::Filter::Fingerprint - DHCP Fingerprint Filter object.

DESCRIPTION

DHCP Fingerprint Filter object.

CONSTRUCTOR

```
 my $filter = Infoblox::DHCP::Filter::Fingerprint->new(
    name            => $string,                                  # required
    fingerprint     => [$fingerprint1, $fingerprint2, ...],      # required, reference to an array of
Infoblox::DHCP::Fingerprint objects
    comment         => $string,                                  # optional
    extattrs        => { $string => $extattr, ... },             # optional / Default is undefined
    extensible_attributes => { $string => $string | $num, $string => [ $string | $num, ... ], ... },
#Optional / Default is undefined
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to DHCP Fingerprint Filter object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $filter = Infoblox::DHCP::Filter::Fingerprint->new(
   name        => 'fingerprint_filter',
   fingerprint => [$fingerprint],
);

#Submit for addition
my $response = $session->add( $filter );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP Fingerprint Filter object:

 name       - Optional. The name of DHCP Fingerprint Filter object.
 comment    - Optional. The comment.
 extattrs   - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
# Get DHCP Fingerprint Filter object by name
my @retrieved_objs = $session->get(
   object    => 'Infoblox::DHCP::Filter::Fingerprint',
   name      => 'fingerprint_filter',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Modify comment
$filter->comment("This is modified object");
# Submit modification
my $response = $session->modify( $filter );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Get the object by name
my @retrieved_objs = $session->get(
   object   => 'Infoblox::DHCP::Filter::Fingerprint',
   name     => 'fingerprint_filter',
);
#Find the desired object from the retrieved list.
my $desired_filter = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_filter );
```

Infoblox::Session->search( )

Use this method to search for DHCP Fingerprint Filter objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for specific DHCP Fingerprint Filter objects:

 name       - Optional. The name of DHCP Fingerprint Filter object (regular expression).
 comment    - Optional. The comment (regular expression).
 extattrs   - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
# Search DHCP Fingerprint Filter object by name
my @retrieved_objs = $session->search(
   object    => 'Infoblox::DHCP::Filter::Fingerprint',
   name      => 'fingerprint_filter',
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of DHCP Fingerprint Filter objects.

comment( )

Use this method to set or retrieve a descriptive comment.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $filter->comment();
#Modify attribute value
$filter->comment('new comment');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Fingerprint Filter object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $filter->extattrs();
#Modify extattrs
$filter->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Fingerprint Filter object.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $extensible_attributes = $filter->extensible_attributes();
#Modify extensible attributes
$filter->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

fingerprint( )

Use this method to set or retrieve a list of DHCP Fingerprint objects.

Parameter

Reference to an array of Infoblox::DHCP::Fingerprint objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $filter->fingerprint();
#Modify attribute value
$filter->fingerprint([$fingerprint]);
```

name( )

Use this method to set or retrieve the name of a DHCP Fingerprint Filter object.

Parameter

The name in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $filter->name();
#Modify attribute value
$filter->name('new_fingerprint_filter');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify, search and remove. This sample also includes error handling for the operations.

#Preparation prior to getting and modifying DHCP Fingerprint Filter object

```
use strict;
use Infoblox;

#refers to Infoblox Appliance IP address
my $host_ip = "192.168.1.2";

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create DHCP Fingerprint Filter object

```
my $fingerprint = Infoblox::DHCP::Fingerprint->new('name' => 'Microsoft Windows 8');
unless ($fingerprint) {
       die("Construct DHCP Fingerprint object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Fingerprint object created successfully\n";

my $filter = Infoblox::DHCP::Filter::Fingerprint->new(
   'name'        => 'fingerprint_filter',
   'fingerprint' => [$fingerprint],
);

unless ($filter) {
       die("Construct DHCP Fingerprint Filter object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Fingerprint Filter object created successfully\n";

my $response = $session->add($filter);

unless ($response) {
    die("Add DHCP Fingerprint Filter object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"DHCP Fingerprint Filter object added successfully \n";
```

#Search for DHCP Fingerprint Filter object

```
my @retrieved_objs = $session->search(
```

```
    object  => 'Infoblox::DHCP::Filter::Fingerprint',
    name    => 'fingerprint_filter',
);

$filter = $retrieved_objs[0];

unless ($filter) {
        die("Search DHCP Fingerprint Filter object object failed: ",
                $session->status_code() . ":" . $session->status_detail());
}
print "Search DHCP Fingerprint Filter object found at least 1 matching entry\n";
```

#Get and modify DHCP Fingerprint Filter object

```
@retrieved_objs = $session->get(
    object  => 'Infoblox::DHCP::Filter::Fingerprint',
    name    => 'fingerprint_filter',
);

$filter = $retrieved_objs[0];

unless ($filter) {
    die("Get DHCP Fingerprint Filter object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Get DHCP Fingerprint Filter object successful \n";

$filter->comment("This is modified object");

$session->modify($filter)
    or die("Modify DHCP Fingerprint Filter object failed",
             $session->status_code() . ":" . $session->status_detail());
print "DHCP Fingerprint Filter object modified successfully \n";
```

#Remove DHCP Fingerprint Filter object

```
@retrieved_objs = $session->get(
    object  => 'Infoblox::DHCP::Filter::Fingerprint',
    name    => 'fingerprint_filter',
);

$filter = $retrieved_objs[0];

unless ($filter) {
    die("Get DHCP Fingerprint Filter object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Get DHCP Fingerprint Filter object successful \n";

$session->remove( $filter )
    or die("Remove DHCP Fingerprint Filter object failed",
            $session->status_code() . ":" . $session->status_detail());
print"DHCP Fingerprint Filter object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::Filter::MAC - DHCP MAC Address Filter object.

DESCRIPTION

An Infoblox appliance can filter address requests by the MAC address and/or vendor prefix (i.e., the first 6 hexadecimal characters in MAC address) of a requesting host. The filter instructs the infoblox appliance either to grant or deny an address request if the requesting host matches the filter.

CONSTRUCTOR

```
 my $mac_filter = Infoblox::DHCP::Filter::MAC->new(
       name                            => $string,                    #Required
       comment                         => $string,                    #Optional / Default is empty
       default_mac_address_expiration => $num,                        #Optional / Default is 0 for never
expire
       enforce_expiration_times        => "true" | "false",           #Optional / Default is "true"
       extattrs                        => { $string => $extattr, ... },      #Optional / Default is
undefined
       extensible_attributes           => { $string => $string | $num, $string => [ $string | $num, ... ],
... }, #Optional / Default is undefined
       lease_time                      => $time,                      #Optional / Default is empty
       option_list                     => [$Option1, $Option2,...],   #Optional / Default is empty
       reserved_for_infoblox           => $string,                    #Optional / Default is empty
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that can be applied to a DHCP MAC Address Filter object.

Infoblox::Session->add( )

Use this method to add a DHCP MAC Address Filter object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
       #Construct a DHCP MAC Address Filter object
       my $mac_filter = Infoblox::DHCP::Filter::MAC->new (
             name                              => "filter_script",
```

```
        comment                         => "Created through script",
        default_mac_address_expiration => "70",
        enforce_expiration_times        => "true",
        reserved_for_infoblox           => "This is reserved for infoblox",
);
#Submit for addition
my $response = $session->add($mac_filter)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP MAC Address Filter object:

 name - Required. Name of the MAC Address Filter.
 extattrs      - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
#Get DHCP MAC Address Filter object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::MAC",
    name   => "filter_script",
);

# get all objects with a given extensible attribute
my @retrieved_objs = $session->get(
    object                => "Infoblox::DHCP::Filter::MAC",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP MAC Address Filter object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the default_mac_address_expiration
$mac_filter->default_mac_address_expiration("1234");
#Submit modification
my $response = $session->modify( $mac_filter );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP MAC Address Filter object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP MAC Address Filter object, then submit this object for removal.

Example

```
#Get DHCP MAC Address Filter object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::MAC",
    name   => "filter_script",
);
#Find the desired object from the retrieved list.
my $desired_mac_filter = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_mac_filter );
```

Infoblox::Session->search( )

Use this method to search for DHCP MAC Address Filter objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific DHCP MAC Address Filter object:

 name - Name of the MAC Address Filter (regular expression).
 comment - Comment string for the MAC Address Filter (regular expression).
```

```
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.

Either name or comment must be specified.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all DHCP MAC Address Filter objects whose name starts with "filter".
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::Filter::MAC",
    name    => "filter.*",
);

# search for all DHCP MAC Address Filter objects whose comment starts with "user1".
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::Filter::MAC",
    comment    => "user1.*",
);

# search all DHCP MAC Address Filter associations with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
   object => "Infoblox::DHCP::Filter::MAC",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that can be used to set and retrieve the attribute values of a DHCP MAC Address Filter object.

comment( )

Use this method to set or retrieve a descriptive comment of a DHCP MAC Address Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $mac_filter->comment();
#Modify comment
$mac_filter->comment("Modified DHCP MAC Address Filter comment");
```

default_mac_address_expiration( )

Use this method to set or retrieve the default mac address expiration time of a DHCP MAC Address Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

By default, the MAC address filter never expires; otherwise, it is the absolute interval when the MAC address filter expires. The maximum value can extend up to 4294967295 secs. The minimum value is 60 secs (1 min).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get default_mac_address_expiration
my $default_mac_address_expiration = $mac_filter->default_mac_address_expiration();
#Modify default_mac_address_expiration
$mac_filter->default_mac_address_expiration("1234");
```

disable( )

Use this method to set or retrieve the disable flag of a DHCP MAC Address Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value for this field is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $mac_filter->disable();
#Modify disable
$mac_filter->disable("true");
```

enforce_expiration_times( )

Use this method to set or retrieve the enforce_expiration_times flag of a DHCP MAC Address Filter object.

Determines whether lease requests will be denied from expired MAC Addresses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the expired flag or "false" to deactivate/unset it. Default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enforce_expiration_times
my $enforce_expiration_times = $mac_filter->enforce_expiration_times();
#Modify enforce_expiration_times
$mac_filter->enforce_expiration_times("false");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP MAC Address Filter object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $mac_filter->extattrs();
#Modify extattrs
$mac_filter->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP MAC Address Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $mac_filter->extensible_attributes();
#Modify extensible attributes
$mac_filter->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

lease_time( )

Use this method to set or retrieve a lease_time attribute of a DHCP MAC address filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter appropriate values in seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get lease_time
my $lease_time = $mac_filter->lease_time();
# Modify lease_time
$mac_filter->lease_time("7200");
```

name( )

Use this method to set or retrieve the name of a DHCP MAC Address Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the DHCP MAC Address filter. Maximum length up to 1024 bytes is supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $mac_filter->name();
#Modify name
$mac_filter->name("filter1");
```

option_list( )

Use this method to set or retrieve the option_list of a DHCP MAC address filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains the Infoblox::DHCP::Option objects. The option list describes filter option configuration settings and various services.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get option_list
my $options = $mac_filter->option_list();
#Modify option_list
$mac_filter->option_list([$option1]);
```

reserved_for_infoblox( )

Set this flag to reserve the MAC address filter for an Infoblox appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Reserved to write comment related to this particular MAC address filter. The length of comment cannot exceed 1024 bytes long.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get reserved_for_infoblox
my $reserved_for_infoblox = $mac_filter->reserved_for_infoblox();
#Modify reserved_for_infoblox
$mac_filter->reserved_for_infoblox("reserved for Infoblox");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP MAC Address Filter object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP MAC Address Filter object

```
#Create a DHCP MAC Address Filter object
my $mac_filter = Infoblox::DHCP::Filter::MAC->new (
       name                          => "script_filter",
       comment                       => "Create through script",
       default_mac_address_expiration => "70",
       enforce_expiration_times      => "true",
       reserved_for_infoblox         => "This is reserved for infoblox",
);

unless($mac_filter) {
     die("Construct mac address filter failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "MAC Address Filter object created successfully\n";

#Verify if the DHCP MAC Address Filter exists in the Infoblox appliance
my $object = $session->get(object => "Infoblox::DHCP::Filter::MAC", name => "script_filter");
unless ($object) {
   print "Mac address filter does not exist on server, safe to add the mac address filter\n";
   $session->add($mac_filter)
      or die("Add mac address filter failed: ",
```

```
            $session->status_code() . ":" . $session->status_detail());
}
print "DHCP MAC Address Filter added successfully\n";
```

#Search for a specific DHCP MAC Address Filter object

```
#Search for all DHCP MAC address filter objects
my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::Filter::MAC",
    name   => ".*" );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search for MAC Address Filter object failed: ",
              $session->status_code() . ":" . $session->status_detail());
}
print "Search MAC Address Filter object found at least 1 matching entry\n";
```

#Get and modify a MAC Address Filter object

```
#Get MAC Address Filter object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::MAC",
    name   => "script_filter" );

my $object = $retrieved_objs[0];
unless ($object) {
    die("Get MAC Address Filter object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get MAC Address Filter object found at least 1 matching entry\n";

#Modify one of the attributes of the obtained MAC Address Filter object
$object->default_mac_address_expiration("1234");

#Apply the changes
$session->modify($object)
    or die("Modify MAC Address Filter object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "MAC Address Filter object modified successfully \n";
```

#Remove a MAC Address Filter object

```
#Get MAC Address Filter object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::MAC",
    name   => "script_filter",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get MAC Address Filter object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get MAC Address Filter object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove MAC Address Filter object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "MAC Address Filter object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::Filter::NAC - DHCP NAC Filter object.

DESCRIPTION

If NAC authentication is configured, the appliance receives authentication responses from NAC authentication servers, and it grants or denies a lease request if the authentication response matches conditions defined by the NAC filters.

CONSTRUCTOR

```
 my $nac_filter = Infoblox::DHCP::Filter::NAC->new(
       name                          => $string,                  #Required
       expression                    => $string,                  #Optional / Default is empty
       extattrs                      => { $string => $extattr, ... },      #Optional / Default is
undefined
       extensible_attributes         => { $string => $string | $num, $string => [ $string | $num, ... ],
... }, #Optional / Default is undefined
       comment                       => $string,                  #Optional / Default is empty
       lease_time                    => $time,                    #Optional / Default is empty
       option_list                   => [$Option1, $Option2,...],  #Optional / Default is empty
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that can be applied to a DHCP NAC Filter object.

Infoblox::Session->add( )

Use this method to add a DHCP NAC Filter object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
       #Construct a DHCP NAC Filter object
       my $nac_filter = Infoblox::DHCP::Filter::NAC->new (
              name                          => "filter_script",
              comment                       => "Created through script",
              expression                    => 'Sophos.ComplianceState="PartialCompliant"',
       );
       #Submit for addition
       my $response = $session->add($nac_filter)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP NAC Filter object:

 name - Required. Name of the NAC Filter.
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
#Get DHCP NAC Filter object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::NAC",
    name   => "filter_script",
);

# get all objects with a given extensible attribute
my @retrieved_objs = $session->get(
    object               => "Infoblox::DHCP::Filter::NAC",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP NAC Filter object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the default_nac_address_expiration
$nac_filter->comment("modified comment");
#Submit modification
my $response = $session->modify( $nac_filter );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP NAC Filter object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP NAC Filter object, then submit this object for removal.

Example

```
#Get DHCP NAC Filter object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::NAC",
    name   => "filter_script",
);
#Find the desired object from the retrieved list.
my $desired_nac_filter = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_nac_filter );
```

Infoblox::Session->search( )

Use this method to search for DHCP NAC Filter objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific DHCP NAC Filter object:

 name - Name of the NAC filter (regular expression).
 comment - Comment string for the NAC filter (regular expression).
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference that contains extensible attributes.

Either a name or comment must be specified.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all DHCP NAC Filter objects whose name starts with "filter".
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::Filter::NAC",
    name    => "filter.*",
);

# search for all DHCP NAC Filter objects whose comment starts with "user1".
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::Filter::NAC",
    comment    => "user1.*",
);

# search all DHCP NAC Filter associations with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
   object => "Infoblox::DHCP::Filter::NAC",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that can be used to set and retrieve the attribute values of a DHCP NAC Filter object.

comment( )

Use this method to set or retrieve a descriptive comment of a DHCP NAC Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format, with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $nac_filter->comment();
#Modify comment
$nac_filter->comment("Modified DHCP NAC Filter comment");
```

expression( )

Use this method to set or retrieve the conditional expression of a DHCP NAC Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An expression in string format, with a maximum of 4096 characters. The expression must comply with the NAC filter expression syntax.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting expression
my $expression = $nac_filter->expression( );
#Modifying expression
$nac_filter->expression('Sophos.ComplianceState="PartialCompliant"');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP NAC Filter object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $nac_filter->extattrs();
#Modify extattrs
$nac_filter->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP NAC Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $nac_filter->extensible_attributes();
#Modify extensible attributes
$nac_filter->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

lease_time( )

Use this method to set or retrieve a lease_time attribute of a DHCP NAC filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter appropriate values in seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get lease_time
my $lease_time = $nac_filter->lease_time();
# Modify lease_time
$nac_filter->lease_time("7200");
```

name( )

Use this method to set or retrieve the name of a DHCP NAC Filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the DHCP NAC filter. The maximum length supported is 1024 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
```

```
my $name = $nac_filter->name();
#Modify name
$nac_filter->name("filter1");
```

option_list( )

Use this method to set or retrieve the option_list of a DHCP NAC filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains the Infoblox::DHCP::Option objects. The option list describes filter option configuration settings and various services.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get option_list
my $options = $nac_filter->option_list();
#Modify option_list
$nac_filter->option_list([$option1]);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP NAC Filter object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP NAC Filter object

```
#Create a DHCP NAC Filter object
my $nac_filter = Infoblox::DHCP::Filter::NAC->new (
       name                          => "script_filter",
       comment                       => "Create through script",
       expression                    => 'Sophos.ComplianceState="PartialCompliant"',
);

unless($nac_filter) {
     die("Construct nac filter failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "NAC Filter object created successfully\n";

#Verify if the DHCP NAC Filter exists in the Infoblox appliance
my $object = $session->get(object => "Infoblox::DHCP::Filter::NAC", name => "script_filter");
unless ($object) {
   print "nac filter does not exist on server, safe to add the nac filter\n";
   $session->add($nac_filter)
      or die("Add nac filter failed: ",
             $session->status_code() . ":" . $session->status_detail());
}
print "DHCP NAC Filter added successfully\n";
```

#Search for a specific DHCP NAC Filter object

```
#Search for all DHCP NAC filter objects
my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::Filter::NAC",
    name   => ".*" );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search for NAC Filter object failed: ",
               $session->status_code() . ":" . $session->status_detail());
}
print "Search NAC Filter object found at least 1 matching entry\n";
```

#Get and modify a NAC Filter object

```
#Get a NAC Filter object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::NAC",
    name   => "script_filter" );

my $object = $retrieved_objs[0];
unless ($object) {
    die("Get NAC Filter object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get NAC Filter object found at least 1 matching entry\n";

#Modify one of the attributes of the obtained NAC Filter object
$object->comment("Modified comment");

#Apply the changes
$session->modify($object)
    or die("Modify NAC Filter object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "NAC Filter object modified successfully \n";
```

#Remove a NAC Filter object

```
#Get a NAC Filter object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::NAC",
    name   => "script_filter",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get NAC Filter object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get NAC Filter object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove NAC Filter object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "NAC Filter object removed successfully \n";

NAME

Infoblox::DHCP::Filter::Option - DHCP filter option object

DESCRIPTION

A Filter::Option defines a DHCP option filter. In the ISC DHCP terms, it defines a class of clients that match a particular (option, value) pair. To define an option filter, add Option to the DHCP Filter object.

CONSTRUCTOR

```
  my $optionFilter = Infoblox::DHCP::Filter::Option->new(
                 name                   => $string,                          #Required
                 apply_as_class         => "true" | "false",                 #Optional / Default is "true"
                 comment                => $string,                          #Optional / Default is empty
                 boot_file              => $filename | undef,                #Optional / Default is
undefined
                 boot_server            => $fqdn | undef,                    #Optional / Default is
undefined
                 extattrs               => { $string => $extattr, ... },     #Optional / Default is
undefined
                 extensible_attributes  => { $string => $string | $num, $string => [ $string | $num, ... ],
... }, #Optional / Default is undefined
                 expression             => $string,                          #Optional / Default is empty
                 lease_time             => $time,                            #Optional / Default is empty
                 next_server            => $fqdn | undef,                    #Optional / Default is
undefined
                 option_list            => [$Option1, $Option2,...],         #Optional / Default is empty
                 option_space           => $string,                          #Optional / Default is "DHCP"
                 pxe_lease_time         => $time,                            #Optional / Default is empty
                );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that can be applied to a DHCP filter option object.

Infoblox::Session->add( )

Use this method to add a DHCP filter option object to the Infoblox device. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my  $optionFilter = Infoblox::DHCP::Filter::Option->new(
       name              => "option_filter",

        );

# Submit for adding a option Filter
my $response = $session->add( $optionFilter );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching DHCP option filter objects from the Infoblox device. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP relayagent filter object:

name - Required. An option filter name in string format.
extattrs              - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
my  @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::Option" ,
    name   => "option_filter",
);

# get all objects with a given extensible attribute
my @retrieved_objs = $session->get(
    object               => "Infoblox::DHCP::Filter::Option",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP option filter object in the Infoblox device. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify boot_server method.
$object->boot_server("myboot_server.com");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP option filter object from the Infoblox device. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Get the object under the same name
my @retrieved_objs = $session->get(
           object  => "Infoblox::DHCP::Filter::Option" ,
           "name"  => "option_filter",
       );

# find the desired object from retrieved list.
my $desired_obj = $retrieved_objs[0];

# Submit for removal
my $response = $session->remove( $desired_obj);
```

Infoblox::Session->search( )

Use this method to search for DHCP option filter object in the Infoblox device. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a DHCP Network object:

 name - Required. An option filter name in string format (regular expression).
 comment - Optional . A comment in string format (regular expression).
 extattrs              - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all DHCP option filter objects
     my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::Filter::Option",
    name   => "option.*",
);

# search all DHCP option filter associations with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
   object => "Infoblox::DHCP::Filter::Option",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of DHCP option filter object

name( )

Use this method to set or retrieve the name of a DHCP option filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the name in string format. The default value for this field is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get name
my $name = $optionFilter->name();
#Modify name
$optionFilter->name("option_filter");
```

apply_as_class( )

Use this method to set or retrieve the "apply_as_class" flag of a DHCP filter option object. If this flag is set to "true" the filter is treated as global DHCP class, e.g it is written to dhcpd config file even if it is not present in any DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the "apply_as_class" flag or "false" to deactivate/unset it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get apply_as_class flag
my $apply_as_class = $optionFilter->apply_as_class();
#Modify apply_as_class flag
$optionFilter->apply_as_class("true");
```

boot_file( )

Use this method to set or retrieve a boot_file attribute of a DHCP filter option object. If this attribute is not set, it will inherit the member level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the file that the client must download.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get boot_file
my $boot_file = $optionFilter->boot_file();
# Modify boot_file
$optionFilter->boot_file("bootfile1");
#Un-override boot_file
$optionFilter->boot_file(undef);
```

boot_server( )

Use this method to set or retrieve a bootserver attribute of a DHCP filter option object. You can specify the name and/or IP address of the boot server that host needs to boot. If this attribute is not set, it will inherit the member level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get boot_server
my $bootserver = $optionFilter->bootserver();
# Modify boot_server
$optionFilter->boot_server("abc.domain.com");
#Un-override boot_server
$optionFilter->boot_server(undef);
```

comment( )

Use this method to set or retrieve the descriptive comment of a DHCP filter option object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $optionFilter->comment();
#Modify comment
$optionFilter->comment("Modified DHCP filter option object comment");
```

expression( )

Use this method to set or retrieve the conditional expression of a DHCP filter option object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An expression in string format, with a maximum of 32768 characters. The expression must comply with the option filter expression syntax.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting expression
my $expression = $optionFilter->expression( );
#Modifying expression
$optionFilter->expression('Sophos.ComplianceState="PartialCompliant"');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Filter Option object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $optionFilter->extattrs();
#Modify extattrs
$optionFilter->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Filter Option object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $optionFilter->extensible_attributes();
#Modify extensible attributes
$optionFilter->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom'
] });
```

lease_time( )

Use this method to set or retrieve a lease_time attribute of a DHCP filter option object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter appropriate values in seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get lease_time
my $lease_time = $optionFilter->lease_time();
# Modify lease_time
$optionFilter->lease_time("7200");
```

next_server( )

Use this method to set or retrieve a next_server attribute of a DHCP filter option object. You can specify the name and/or IP address of the next server that the host needs to boot. If this attribute is not set, it will inherit the member level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). The next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get next_server
my $nextserver = $optionFilter->next_server();
# Modify next_server
$optionFilter->next_server("blue.domain.com");
#Un-override next_server
$optionFilter->next_server(undef);
```

option_list( )

Use this method to set or retrieve the option_list of a DHCP filter option object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects. Option list describe filter option configuration settings and various services.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get option_list
my $options = $optionFilter->option_list();
#Modify option_list
$optionFilter->option_list([$option1]);
```

option_space( )

Use this method to retrieve the option_space of a DHCP filter option object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the option space value in string format. The default value of option_space is DHCP.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get option_space
my $options = $optionFilter->option_space();
#Modify option_space
```

```
$optionFilter->option_space("Infoblox_DHCP");
```

pxe_lease_time( )

Use this method to set or retrieve a pxe_lease_time attribute of a DHCP filter option object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter appropriate values in seconds.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get pxe_lease_time
my $pxe_lease_time = $optionFilter->pxe_lease_time();
# Modify pxe_lease_time
$optionFilter->pxe_lease_time("3600");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP option filter object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox device

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP Filter Option object

```
my  $optionfilter = Infoblox::DHCP::Filter::Option->new(

       name             => "option_filter",
       next_server      => "abc_server.com" ,
       boot_file        => "file1" ,
       boot_server      => "boot_server.com" ,
       lease_time       => "7200",
       pxe_lease_time   => "3600",
              );

unless ($optionfilter) {
   die("Construct DHCP Filter::Option failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Filter::Option object created successfully\n";
my $response = $session->add($optionfilter)
       or die("Add DHCP Filter Option failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "DHCP Filter Option added successfully\n";
```

#Search for a specific DHCP Filter Option

```
#Search the  DHCP Filter Option
my @retrieved_objs = $session->search(
    object             => "Infoblox::DHCP::Filter::Option",
```

```
    name               => "option.*",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search DHCP Filter Option  failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Search DHCP Filter Option found at least 1 matching entry\n";
```

#Get and modify a DHCP Filter Option attribute

```
#Get  DHCP Filter Option through the session
my  @retrieved_objs = $session->get(

              object      =>"Infoblox::DHCP::Filter::Option" ,
              name        => "option_filter",
                      );

my $object = $retrieved_objs[0];
unless ($object) {
    die("Get option filter object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Get DHCP Filter Option found at least 1 matching entry\n";

#Modify one of the attributes of the specified DHCP Filter Option attribute

$object->boot_server("another_Server");

#Apply the changes
$session->modify($object)
    or die("Modify DHCP Filter Option attribute failed: ",
           $session->status_code() . ":" . $session->status_detail());

print "DHCP Filter Option object modified successfully \n";
```

#Remove a DHCP Filter Option Object

```
 #Get object through the session
 my @retrieved_objs = $session->get(

           object  => "Infoblox::DHCP::Filter::Option" ,
           "name"  => "option_filter",
                   );

   my $object = $retrieved_objs[0];

   unless ($object) {
    die("Get a DHCP Filter Optionobject failed: ",
        $session->status_code() . ":" . $session->status_detail());
    }

print "Get a DHCP Filter Option object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove a DHCP Filter Option failed: ",
        $session->status_code() . ":" . $session->status_detail());

print "DHCP Filter Option removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::Filter::RelayAgent - DHCP relay agent filter object

---

DESCRIPTION

The Infoblox appliance can screen address requests through relay agent filters (DHCP option 82) that assist the agents in forwarding address assignments across the proper circuit. When a relay agent receives the DHCPDISCOVER message, it can add one or two agent IDs in the DHCP option 82 suboption fields to the message. If the agent ID strings match those defined in a relay agent filter applied to a DHCP address range, the Infoblox appliance either assigns addresses from that range or denies the request (based on previously configured parameters; that is, the Grant lease and Deny lease parameters).

CONSTRUCTOR

```
  my $relayagentFilter = Infoblox::DHCP::Filter::RelayAgent->new(
                  name                        => $string | $ipv4addr,
# Required
                  comment                     => $string,
# Optional / Default is empty
                  circuit_id_name             => $string,
# Optional / Default is empty
                  extattrs                    => { $string => $extattr, ... },
# Optional / Default is undefined
                  extensible_attributes       => { $string => $string | $num, $string => [ $string | $num,
... ], ... }, # Optional / Default is undefined
                  remote_id_name              => $string,
# Optional / Default is empty
                  is_circuit_id               => $string,
# Optional / Default is empty
                  is_remote_id                => $string,
# Optional / Default is empty
                  is_circuit_id_substring     => 'true' | 'false',
# Optional / Default is 'false'
                  circuit_id_substring_offset => $uint,
# Optional / Default is undefined
                  circuit_id_substring_length => $uint,
# Optional / Default is undefined
                  is_remote_id_substring      => 'true' | 'false',
# Optional / Default is 'false'
                  remote_id_substring_offset  => $uint,
# Optional / Default is undefined
                  remote_id_substring_length  => $uint,
```

```
# Optional / Default is undefined
                );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that can be applied to a DHCP relay agent filter object.

Infoblox::Session->add( )

Use this method to add a DHCP relay agent filter object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my  $relayagentFilter = Infoblox::DHCP::Filter::RelayAgent->new(
       name             => "relayagent_filter",
       circuit_id_name  => "circuit",
       remote_id_name   => "remote"
        );

# Submit for adding a relay agent filter
my $response = $session->add( $relayagentFilter );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching DHCP relay agent filter objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP relay agent filter object:

 name - Required. A relay agent filter name in string format or in ipv4address format.
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
my  @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::Filter::RelayAgent" ,
    name   => "relayagent_filter",
);

# get all objects with a given extensible attribute
my @retrieved_objs = $session->get(
    object               => "Infoblox::DHCP::Filter::RelayAgent",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP relay agent filter object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify circuit id name method.
$object->circuit_id_name("diff_Circuit");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP relay agent filter object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific object, then submit this object for removal.

Example

```
# Get the object under the same name
my @retrieved_objs = $session->get(
           object  => "Infoblox::DHCP::Filter::RelayAgent" ,
```

```
            "name"   => "relayagent_filter",
        );

    # find the desired object from retrieved list.
    my $desired_obj = $retrieved_objs[0];

    # Submit for removal
    my $response = $session->remove( $desired_obj);
```

Infoblox::Session->search( )

Use this method to search for a DHCP relay agent filter object in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a DHCP Network object:

 name - Required. A relay agent filter name in string format (regular expression).
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
 comment - Optional . A comment in string format (regular expression).
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all DHCP relayagent objects
     my @retrieved_objs = $session->search(
               object   => "Infoblox::DHCP::Filter::RelayAgent",
               name     => 'relayagent\..*',
               );

# search all DHCP relay agent associations with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
   object => "Infoblox::DHCP::Filter::RelayAgent",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP relay agent filter object.

name( )

Use this method to set or retrieve the name of a DHCP relay agent filter object. The name can be an IP address or name of the router acting as relay agent.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the name in string format or in ipv4addr format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2). The default value for this field is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get name
my $name = $relayagentFilter->name()
# Modify name
$relayagentFilter->name("relay_filter");
```

comment( )

Use this method to set or retrieve the descriptive comment of a DHCP relay agent filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $relayagentFilter->comment();
#Modify comment
$relayagentFilter->comment("Modified DHCP relay agent filter object comment");
```

circuit_id_name( )

Use this method to set or retrieve a circuit_id_name of a DHCP relay agent filter object. This filter identifies the circuit between the remote host and the relay agent. For example, the identifier can be the ingress interface number of the circuit access unit, perhaps concatenated with the unit ID number and slot number. Also, the circuit ID can be an ATM virtual circuit ID or cable data virtual circuit ID.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify circuit id name in string format. example: Text String: 001122334455 Binary String: \x00\x11\x22\x33\x44\x55. The default value for this field is empty.

To reset this value, set it to an empty string together with the is_circuit_id flag (anything except "Matches_Value").

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get circuit_id_name
my $circuit_id_name = $relayagentFilter->circuit_id_name();
# Modify circuit_id_name
$relayagentFilter->circuit_id_name("001122334455");
# Set is_circuit_id to "Not_Set"
$relayagentFilter->is_circuit_id("Not_Set");
# Set circuit_id_name to empty string
$relayagentFilter->circuit_id_name("");
```

circuit_id_substring_length( )

Use this method to set or retrive the circuit ID substring length.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get circuit_id_substring_length value
my $circuit_id_substring_length = $relayagentfilter->circuit_id_substring_length();

#modify circuit_id_substring_length value
$relayagentfilter->circuit_id_substring_length(10);
```

circuit_id_substring_offset( )

Use this method to set or retrive the circuit ID substring offset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get circuit_id_substring_offset value
my $circuit_id_substring_offset = $relayagentfilter->circuit_id_substring_offset();

#modify circuit_id_substring_offset value
$relayagentfilter->circuit_id_substring_offset(10);
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP relay agent filter object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $relayagentFilter->extattrs();
#Modify extattrs
$relayagentFilter->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP relay agent filter object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $relayagentFilter->extensible_attributes();
#Modify extensible attributes
$relayagentFilter->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

remote_id_name( )

Use this method to set or retrieve a remote ID name attribute of a relay agent filter object. This filter identifies the remote host. The remote ID name can represent many different things such as the caller ID telephone number for a dial-up connection, a user name for logging in to the ISP, a modem ID, etc. When the remote ID name is defined on the relay agent, the DHCP server will have a trusted relationship to identify the remote host. The remote ID name is considered as a trusted identifier.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify remote_id_name in string format. example: Text String: 001122334455 Binary String: \x00\x11\x22\x33\x44\x55. The default value for this field is empty.

To reset this value, set it to an empty string together with the is_remote_id flag (anything except "Matches_Value").

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get remote_id_name
my $remote_id_name = $relayagentFilter->remote_id_name();
# Modify remote_id_name
$relayagentFilter->remote_id_name("\x00\x11\x22\x33\x44\x55");
# Set is_remote_id to "Not_Set"
$relayagentFilter->is_remote_id("Not_Set");
# Set remote_id_name to empty string
$relayagentFilter->remote_id_name("");
```

remote_id_substring_length( )

Use this method to set or retrive the remote ID substring length.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get remote_id_substring_length value
my $remote_id_substring_length = $relayagentfilter->remote_id_substring_length();

#modify remote_id_substring_length value
$relayagentfilter->remote_id_substring_length(10);
```

remote_id_substring_offset( )

Use this method to set or retrive the remote ID substring offset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an unsigned integer.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get remote_id_substring_offset value
my $remote_id_substring_offset = $relayagentfilter->remote_id_substring_offset();

#modify remote_id_substring_offset value
$relayagentfilter->remote_id_substring_offset(10);
```

is_circuit_id( )

Use this method to set or retrieve the is_circuit_id flag of a DHCP relay agent filter object. The possible values for the is_circuit_id flag are Any, Not_Set, Matches_Value. The circuit_id value takes effect only if the value is Matches_Value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify is_circuit_id in string format. example: Text String: Any

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get is_circuit_id
my $is_circuit_id = $relayagentFilter->is_circuit_id();
# Modify is_circuit_id
$relayagentFilter->is_circuit_id("Any");
```

is_circuit_id_substring( )

Use this method to set or retrive the flag that indicates whether the substring of circuit ID, instead of the full circuit ID, is matched.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable the circuit ID substring match or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get is_circuit_id_substring
my $is_circuit_id_substring = $relayagentFilter->is_circuit_id_substring();
# Modify is_circuit_id_substring
$relayagentFilter->is_circuit_id_substring("true");
```

is_remote_id( )

Use this method to set or retrieve the is_remote_id flag of a DHCP relay agent filter object. The possible values for the is_remote_id flag are Any, Not_Set, Matches_Value. The remote_id value takes effect only if the value is Matches_Value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify is_remote_id in string format. example: Text String: Not_Set

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get is_remote_id
my $is_remote_id = $relayagentFilter->is_remote_id();
# Modify is_remote_id
$relayagentFilter->is_remote_id("Not_Set");
```

is_remote_id_substring( )

Use this method to set or retrive the flag that indicates whether the substring of the remote ID, instead of the full remote ID, is matched.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable remote id substring match or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get is_remote_id_substring
my $is_remote_id_substring = $relayagentFilter->is_remote_id_substring();
# Modify is_remote_id_substring
```

```
$relayagentFilter->is_remote_id_substring("true");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP relay agent filter object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a FilterRule relayagent filter object>

my $filter = Infoblox::DHCP::FilterRule::RelayAgent->new(
               filter_name => "relayagent_filter",
               permission => "grant" );
```

#Create a DHCP relay agent filter object

```
my  $relayagentfilter = Infoblox::DHCP::Filter::RelayAgent->new(

       name             => "relayagent_filter",
       circuit_id_name  => "circuit",
       remote_id_name   => "remote"
             );
        my $response = $session->add($relayagentfilter)
       or die("Add DHCP Relay Agent Filter failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "DHCP Relay Agent Filter added successfully\n";
```

#Search for a specific DHCP relay agent filter

```
#Search the DHCP Relay Agent Filter
my @retrieved_objs = $session->search(
               object => "Infoblox::DHCP::Filter::RelayAgent",
               name   => "relayagent.*",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search DHCP Relay Agent Filter  failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Search DHCP relay agent filter found at least 1 matching entry\n";
```

#Get and modify a DHCP relay agent filter attribute

```
#Get  DHCP Relay Agent Filter through the session
my  @retrieved_objs = $session->get(
              object => "Infoblox::DHCP::Filter::RelayAgent" ,
              name   => "relayagent_filter",
       );
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get Network object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Get DHCP relay agent filter found at least 1 matching entry\n";
```

```
#Modify the attributes of the specified DHCP Relay Agent Filter object
$object->circuit_id_name("diff_Circuit");
$object->remote_id_name("diff_remote");
$session->modify($object)
    or die("Modify DHCP Relay Agent Filter attribute failed: ",
           $session->status_code() . ":" . $session->status_detail());

print "DHCP Relay Agent Filter object modified successfully \n";

#Create the Network object with the member
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/8",
    comment => "add network",
);
unless($network) {
       die("Construct Network object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network object created successfully\n";

#Add the Network object into the Infoblox appliance through a session
$session->add($network)
    or die("Add Network object failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "Network object added to Infoblox appliance successfully\n";
```

#Create a DHCP Range object that uses the relayagent filter

```
my $dhcp_range = Infoblox::DHCP::Range->new(
        end_addr                => "10.0.0.10",
        network                 => "10.0.0.0/8",
        start_addr              => "10.0.0.1",
        authority               => "true",
        filters                 => [$filter],
);
unless($dhcp_range) {
       die("Construct DHCP Range object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "DHCP Range object created successfully\n";

#Add the DHCP Range object into the Infoblox appliance through a session
$session->add($dhcp_range)
    or die("Add DHCP Range object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Range object added to the network successfully\n";

#Remove the Network object into the Infoblox appliance through a session
$session->remove($network)
    or die("Remove Network object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "Network object removed from Infoblox appliance successfully\n";
```

#Remove a DHCP relay agent filter Object

```
 #Get object through the session
 my @retrieved_objs = $session->get(
         object   => "Infoblox::DHCP::Filter::RelayAgent" ,
         name     => "relayagent_filter",
       );
  my $object = $retrieved_objs[0];    unless ($object) {
    die("Get a DHCP Relay Agent Filterobject failed: ",
        $session->status_code() . ":" . $session->status_detail());
  }

print "Get a DHCP relay agent filter object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove a DHCP Relay Agent Filter failed: ",
        $session->status_code() . ":" . $session->status_detail());

print "DHCP relay agent filter removed successfully \n";

NAME

Infoblox::DHCP::FilterRule::Fingerprint - DHCP Fingerprint Filter Rule object.

DESCRIPTION

DHCP Fingerprint Filter Rule object.

CONSTRUCTOR

```
my $filter_rule = Infoblox::DHCP::FilterRule::Fingerprint->new(
      filter_name    => $string,           #Required
      permission     => "grant" | "deny", #Required
);
```

MODULE METHODS

The following functions are available to apply to a DHCP Fingerprint Filter Rule object.

Infoblox::DHCP::Range->filters( )

Use this method to add a DHCP fingerprint Filter Rule object to the DHCP Range on the Infoblox appliance. See Infoblox::DHCP::Range->filters() for parameters and return values.

Example

```
#Construct a DHCP Fingerprint Filter Rule object
my $filter_rule = Infoblox::DHCP::FilterRule::Fingerprint->new(
      filter_name    => "filter",
      permission     => "grant",
);

#Add Fingerprint Filter Rule to the DHCP Range object.
my $response = $dhcp_range->filters([$filter_rule]);
```

Infoblox::DHCP::RangeTemplate->filters( )

Use this method to add a DHCP fingerprint Filter Rule object to the DHCP Range Template on the Infoblox appliance. See Infoblox::DHCP::RangeTemplate->filters() for parameters and return values.

Example

```
#Construct a DHCP Fingerprint Filter Rule object
my $filter_rule = Infoblox::DHCP::FilterRule::Fingerprint->new(
      filter_name    => "filter",
      permission     => "grant",
);

#Add Fingerprint Filter Rule to the DHCP Range Template object.
my $response = $dhcp_range_template->filters([$filter_rule]);
```

METHODS

This section describes all the methods that can be used to set and retrieve the attribute values of a DHCP Fingerprint Filter Rule object.

filter_name( )

Use this method to set or retrieve the filter_name of a DHCP Fingerprint Filter Rule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the DHCP Fingerprint filter. Maximum length up to 1024 bytes is supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get filter_name
my $filter_name = $filter_rule->filter_name();
#Modify filter_name
$filter_rule->filter_name("fingerprint filter");
```

permission( )

Use this method to set or retrieve the permission of a DHCP Fingerprint Filter Rule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the permission in string format. The permission can be either "grant" or "deny".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get permission
my $permission = $filter_rule->permission();
#Modify permission
$filter_rule->permission("deny");
```

NAME

Infoblox::DHCP::FilterRule::MAC - DHCP MAC Address Filter Rule object.

DESCRIPTION

MAC Address Filter Rule allows a user to grant/deny the lease of an IP defined in DHCP Range.

CONSTRUCTOR

```
my $mac_filter_rule = Infoblox::DHCP::FilterRule::MAC->new(
      filter_name    => $string,          #Required
      permission     => "grant" | "deny", #Required
);
```

MODULE METHODS

The following functions can be applied to a DHCP MAC Filter Rule object.

Infoblox::DHCP::Range->filters( )

Use this method to add a DHCP MAC Address Filter Rule object to the DHCP Range on an Infoblox appliance. See Infoblox::DHCP::Range->filters() for parameters and return values.

Example

```
#Construct a DHCP MAC Address Filter Rule object
my $mac_filter_rule1 = Infoblox::DHCP::FilterRule::MAC->new(
      filter_name    => "filter1",
      permission     => "grant",
);

#Add MAC Address Filter Rule to the DHCP Range object.
my $response = $dhcp_range->filters([$mac_filter_rule1]);
```

METHODS

This section describes all the methods that can be used to set and retrieve the attribute values of a DHCP MAC Address Filter Rule object.

filter_name( )

Use this method to set or retrieve the filter_name of a DHCP MAC Address Filter Rule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the DHCP MAC Address filter. Maximum length up to 1024 bytes is supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get filter_name
my $filter_name = $mac_filter_rule->filter_name();
#Modify filter_name
$mac_filter_rule->filter_name("filter2");
```

permission( )

Use this method to set or retrieve the permission of a DHCP MAC Address Filter Rule object.

Permission indicates whether members of this MAC address filter are allowed or denied an IP address from the defined DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Permission value can be either "grant" or "deny".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get permission
my $permission = $mac_filter_rule->permission();
#Modify permission
$mac_filter_rule->permission("deny");
```

SAMPLE CODE

The following sample code demonstrates different functions that can be applied to an object such as modify. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP MAC Address Filter Rule object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create the Network object
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/8",
    comment => "add network",

$session->add($mac_filter)
    or die("Add MAC Address Filter object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "MAC Address Filter object added to Infoblox appliance successfully\n";
```

#Create a DHCP MAC Address Filter Rule object

```
#Construct a DHCP MAC Address Filter Rule object
my $mac_filter_rule1 = Infoblox::DHCP::FilterRule::MAC->new(
      filter_name   => "filter1",
      permission    => "grant",
);

unless ( $mac_filter_rule1 ) {
       die("Construct MAC Address Filter Rule failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail() );
}
print "MAC Address Filter Rule object created successfully\n";

#Create the DHCP Range object with this MAC Address Filter Rule.
my $dhcp_range = Infoblox::DHCP::Range->new(
        end_addr   => "10.0.0.10",
        network    => "10.0.0.0/8",
        start_addr => "10.0.0.1",
        filters    => [ $mac_filter_rule1 ],
);
unless($dhcp_range) {
       die("Construct DHCP Range object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Range object created successfully\n";

#Add the DHCP Range object into the Infoblox appliance through a session
$session->add($dhcp_range)
    or die("Add DHCP Range object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Range object added to Infoblox appliance successfully\n";
```

#Get and modify a MAC Address Filter Rule object

```
#Get MAC Address Filter Rule object from the DHCP Range object through session
my @retrieved_objs = $session->get(
    object      => "Infoblox::DHCP::Range",
    start_addr  => "10.0.0.1",
);

my $object = $retrieved_objs[0];
my $filter = $object->filters();

my @filters = @{$filter};

my $mac_filterrule = $filters[0];

#Modify one of the attributes of the obtained MAC Address Filter Rule object
$mac_filterrule->permission("deny");
$object->filters([$mac_filterrule]);

#Apply the changes
$session->modify($object)
    or die("Modify MAC Address Filter Rule object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "MAC Address Filter Rule object modified and added to the DHCP Range object successfully \n";
```

#Remove a MAC Address Filter Rule object

```
$object->filters([]);

my $response = $session->modify($object);
```

```
unless($response) {
       die("Remove MAC Address Filter Rule failed: ",
                session->status_code() . ":" . session->status_detail() );
}
print "MAC Address Filter Rule object removed successfully \n";

#Submit the network object for removal
$session->remove($network)
    or die("Remove Network object failed: ",

NAME

Infoblox::DHCP::FilterRule::NAC - DHCP NAC Filter Rule object.

DESCRIPTION

A NAC Filter Rule object is used to grant or deny the lease of an IP address in a DHCP range based on whether the authentication response matches the NAC filter.

CONSTRUCTOR

```
my $nac_filter_rule = Infoblox::DHCP::FilterRule::NAC->new(
      filter_name    => $string,          #Required
      permission     => "grant" | "deny", #Required
);
```

MODULE METHODS

The following functions can be applied to a DHCP NAC Filter Rule object.

Infoblox::DHCP::Range->filters( )

Use this method to add a DHCP NAC Filter Rule object to a DHCP range. See Infoblox::DHCP::Range->filters() for parameters and return values.

Example

```
#Construct a DHCP NAC Filter Rule object
my $nac_filter_rule1 = Infoblox::DHCP::FilterRule::NAC->new(
      filter_name    => "filter1",
      permission     => "grant",
);

#Add a NAC Filter Rule to the DHCP Range object.
my $response = $dhcp_range->filters([$nac_filter_rule1]);
```

METHODS

This section describes all the methods that can be used to set and retrieve the attribute values of a DHCP NAC Filter Rule object.

filter_name( )

Use this method to set or retrieve the filter_name of a DHCP NAC Filter Rule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the DHCP NAC filter. The maximum length supported is 1024 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get filter_name
my $filter_name = $nac_filter_rule->filter_name();
#Modify filter_name
$nac_filter_rule->filter_name("filter2");
```

permission( )

Use this method to set or retrieve the permission of a DHCP NAC Filter Rule object.

The permission indicates whether a DHCP client whose NAC authentication response matches this NAC filter is allowed or denied a lease from the defined DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The permission value can be either "grant" or "deny".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get permission
my $permission = $nac_filter_rule->permission();
#Modify permission
$nac_filter_rule->permission("deny");
```

SAMPLE CODE

The following sample code demonstrates different functions that can be applied to an object such as modify. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP NAC Filter Rule object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",

NAME

Infoblox::DHCP::FilterRule::Option - DHCP filter rule option object.

DESCRIPTION

A DHCP filter rule option object gives the ability to grant and/or deny a lease of an IP defined in DHCP Range.

CONSTRUCTOR

```
my $FilterRuleOption = Infoblox::DHCP::FilterRule::Option->new(
              filter_name   =>  $string,          #Required
              permission    =>  "grant" | "deny", #Required
          );
```

MODULE METHODS

The following functions are available to apply to a DHCP filter rule option object.

Infoblox::DHCP::Range->filters( )

Use this function to specify filters at the DHCP range level. See details for Infoblox::DHCP::Range objects

Example

```
#Construct DHCP filter rule option object
my $filter = Infoblox::DHCP::FilterRule::Option->new(
    filter_name => "filter1",
    permission  => "grant"
);

# Configure  filters
my $response = $range->filters([$res]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP filter rule option object.

filter_name( )

Use this method to set or retrieve the filter name of a DHCP filter rule option object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify filter name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get filters from  range
my $resp = $range->filters();
# Modify filters
$range->filters([$res]);
```

permission( )

Use this method to set or retrieve the permission of a DHCP filter rule option object. When selecting Grant lease, you need to assign addresses from the address range to requesting hosts whose user class (as defined on their network adapter) matches an entry in the option filter rules. When selecting Deny lease, you need to refuse an address request from a host whose user class matches an entry in the option filter rules.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The permission can be either "grant" or "deny". The default value is "grant" lease.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get permission
 $res->permission();
#modify permission value
$res->permission("deny");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, modify. Also, this sample includes error handling for the operations.

##Preparation prior to a DHCP filter rule option object insertion

NAME

Infoblox::DHCP::FilterRule::RelayAgent - DHCP RelayAgent Filter Rule object.

DESCRIPTION

A relay agent adds the circuit ID and Remote ID information to the client request and sends it to DHCP Server. Infoblox appliance uses Relay Agent Filter Rules to grant/deny the lease to a request that comes from those Relay Agents.

CONSTRUCTOR

```
my $ra_filter_rule = Infoblox::DHCP::FilterRule::RelayAgent->new(
      filter_name    => $string,          #Required
      permission     => "grant" | "deny", #Required
);
```

MODULE METHODS

The following functions are available to apply to a DHCP RelayAgent Filter Rule object.

Infoblox::DHCP::Range->filters( )

Use this method to add a DHCP RelayAgent Filter Rule object to the DHCP Range on the Infoblox appliance. See Infoblox::DHCP::Range->filters() for parameters and return values.

Example

```
#Construct a DHCP RelayAgent Filter Rule object
my $ra_filter_rule1 = Infoblox::DHCP::FilterRule::RelayAgent->new(
      filter_name    => "filter1",
      permission     => "grant",
);

#Add RelayAgent Filter Rule to the DHCP Range object.
my $response = $dhcp_range->filters([$ra_filter_rule1]);
```

METHODS

This section describes all the methods that can be used to set and retrieve the attribute values of a DHCP RelayAgent Filter Rule object.

filter_name( )

Use this method to set or retrieve the filter_name of a DHCP RelayAgent Filter Rule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the DHCP RelayAgent filter. Maximum length up to 1024 bytes is supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get filter_name
my $filter_name = $ra_filter_rule->filter_name();
#Modify filter_name
$ra_filter_rule->filter_name("filter2");
```

permission( )

Use this method to set or retrieve the permission of a DHCP RelayAgent Filter Rule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the permission in string format. The permission can be either "grant" or "deny".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get permission
my $permission = $ra_filter_rule->permission();
#Modify permission
$ra_filter_rule->permission("deny");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as modify. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP RelayAgent Filter Rule object insertion

NAME

Infoblox::DHCP::Fingerprint - DHCP Fingerprint object.

DESCRIPTION

DHCP Fingerprint object.

CONSTRUCTOR

```
my $fingerprint = Infoblox::DHCP::Fingerprint->new(
   name                  => $string,                              # required
   device_class          => $string,                              # required
   type                  => 'CUSTOM' | 'STANDARD',                # optional, default is 'CUSTOM'
   comment               => $string,                              # optional
   disable               => 'true' | 'false',                     # optional, default is 'false'
   vendor_id             => [$string1, $string2, ...],            # optional
   option_sequence       => [$string1, $string2, ...],            # optional
   ipv6_option_sequence  => [$string1, $string2, ...],            # optional
   extattrs              => { $string => $extattr, ... },         # optional / Default is undefined
   extensible_attributes => $extattrs,                            # optional
);
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

At least one of option_sequence, ipv6_option_sequence or vendor_id must be defined.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to DHCP Fingerprint objects.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance if the type value is 'CUSTOM'. Otherwise this method is not supported. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $fingerprint = Infoblox::DHCP::Fingerprint->new(
   name => 'Infoblox',
   device_class => 'Inc',
```

```
    option_sequence => ['1'],
);

#Submit for addition
my $response = $session->add( $fingerprint );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP Fingerprint object:

 name                       - Optional. The name of the DHPC Fingerprint object.
 device_class               - Optional. The class of DHCP Fingerprint object.
 type                       - Optional. The type of DHCP Fingerprint object.
 comment                    - Optional. The comment.
 extattrs                   - Optional. A hash reference containing extensible attributes.
 extensible_attributes      - Optional. A hash reference containing extensible attributes.
```

Example

```
# Get DHCP Fingerprint object by name
my @retrieved_objs = $session->get(
    object  => 'Infoblox::DHCP::Fingerprint',
    name    => 'Infoblox',
);

# Get all base DHCP Fingerprint objects
my @retrieved_objs = $session->get(
    object  => 'Infoblox::DHCP::Fingerprint',
    type    => 'STANDARD',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Modify comment
$fingerprint->comment("This is modified object");
# Submit modification
my $response = $session->modify( $fingerprint );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance if the type value is 'CUSTOM'. Otherwise this method is not supported. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Get the object by name
my @retrieved_objs = $session->get(
    object    => 'Infoblox::DHCP::Fingerprint',
    name      => 'Infoblox',
);
#Find the desired object from the retrieved list.
my $desired_fingerprint = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_fingerprint );
```

Infoblox::Session->search( )

Use this method to search for DHCP Fingerprint objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for specific DHCP Fingerprint objects:

  name                       - Optional. The name of the DHPC Fingerprint object (regular
expression).
  device_class               - Optional. The class of DHCP Fingerprint object (regular expression).
  type                       - Optional. The type of DHCP Fingerprint object.
```

```
 comment                    - Optional. The comment (regular expression).
 extattrs                   - Optional. A hash reference containing extensible attributes.
 extensible_attributes      - Optional. A hash reference containing extensible attributes.
```

Example

```
# Search DHCP Fingerprint object by name
my @retrieved_objs = $session->search(
   object  => 'Infoblox::DHCP::Fingerprint',
   name    => 'Infoblox',
);

# Search all base DHCP Fingerprint objects
my @retrieved_objs = $session->search(
   object  => 'Infoblox::DHCP::Fingerprint',
   type    => 'STANDARD',
);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of DHCP Fingerprint objects.

comment( )

Use this method to set or retrieve a descriptive comment.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->comment();
#Modify attribute value
$fingerprint->comment('new comment');
```

device_class( )

Use this method to set or retrieve a class of DHCP Fingerprint object.

Parameter

The class in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->device_class();
#Modify attribute value
$fingerprint->device_class('Infoblox Inc.');
```

name( )

Use this method to set or retrieve a name of DHCP Fingerprint object.

Parameter

The name in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->name();
#Modify attribute value
$fingerprint->name('custom fingerprint');
```

disable( )

Use this method to enable or disable a DHCP Fingerprint object.

If a DHCP Fingerprint object is enabled, the option number sequence and vendor_ids for this operating system or device will be included in the list of fingerprints to match incoming lease requests.

Parameter

Specify "true" to disable DHCP Fingerprint object or "false" to enable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->disable();
#Modify attribute value
$fingerprint->disable('false');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Fingerprint object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $fingerprint->extattrs();
#Modify extattrs
$fingerprint->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with DHCP Fingerprint objects.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->extensible_attributes();
#Modify attribute value
$fingerprint->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

option_sequence( )

Use this method to set or retrieve a list (comma separated list) of IPv4 option number sequences of the device or operating system.

At least one of option_sequence, ipv6_option_sequence or vendor_id must be defined.

Parameter

Reference to an array of IPv4 option number sequence (comma separated list) in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->option_sequence();
#Modify attribute value
$fingerprint->option_sequence(['1,2,3']);
```

ipv6_option_sequence( )

Use this method to set or retrieve a list (comma separated list) of IPv6 option number sequences of the device or operating system.

At least one of option_sequence, ipv6_option_sequence or vendor_id must be defined.

Parameter

Reference to an array of IPv6 option number sequence (comma separated list) in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->ipv6_option_sequence();
#Modify attribute value
$fingerprint->ipv6_option_sequence(['1,2,3']);
```

type( )

Use this method to set or retrieve the type of the DHCP Fingerprint object.

Parameter

Valid value can be 'STANDARD' or 'CUSTOM'. Standard fingerprints are the fingerprints from fingerbank. Custom fingerprints are user defined fingerprints.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->type();
#Modify attribute value
$fingerprint->type('CUSTOM');
```

vendor_id( )

Use this method to set or retrieve a list of vendor IDs of the device or operating system.

At least one of option_sequence, ipv6_option_sequence or vendor_id must be defined.

Parameter

Reference to an array of vendor ID in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attribute value
my $value = $fingerprint->vendor_id();
#Modify attribute value
$fingerprint->vendor_id(['3','4']);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify, search and remove. This sample also includes error handling for the operations.

#Preparation prior to getting and modifying DHCP Fingerprint object

```
use strict;
use Infoblox;

#refers to Infoblox Appliance IP address
my $host_ip = "192.168.1.2";

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create DHCP Fingerprint object

```
my $fingerprint = Infoblox::DHCP::Fingerprint->new(
   'name' => 'Infoblox',
   'device_class' => 'Inc',
   'option_sequence' => ['1'],
);

unless ($fingerprint) {
       die("Construct DHCP Fingerprint object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Fingerprint object created successfully\n";

my $response = $session->add($fingerprint);

unless ($response) {
    die("Add DHCP Fingerprint object failed: ",
           $session->status_code() . ":" . $session->status_detail());
}
print"DHCP Fingerprint object added successfully \n";
```

#Search for DHCP Fingerprint object

```
my @retrieved_objs = $session->search(
   object   => 'Infoblox::DHCP::Fingerprint',
   name     => 'Infoblox',
);

$fingerprint = $retrieved_objs[0];

unless ($fingerprint) {
        die("Search DHCP Fingerprint object object failed: ",
                $session->status_code() . ":" . $session->status_detail());
}
print "Search DHCP Fingerprint object found at least 1 matching entry\n";
```

#Get and modify DHCP Fingerprint object

```
@retrieved_objs = $session->get(
   object  => 'Infoblox::DHCP::Fingerprint',
   name    => 'Infoblox',
```

```
);

$fingerprint = $retrieved_objs[0];

unless ($fingerprint) {
    die("Get DHCP Fingerprint object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Get DHCP Fingerprint object successful \n";

$fingerprint->comment("This is modified object");

$session->modify($fingerprint)
   or die("Modify DHCP Fingerprint object failed",
             $session->status_code() . ":" . $session->status_detail());
print "DHCP Fingerprint object modified successfully \n";
```

#Remove DHCP Fingerprint object

```
@retrieved_objs = $session->get(
   object   => 'Infoblox::DHCP::Fingerprint',
   name     => 'Infoblox',
);

$fingerprint = $retrieved_objs[0];

unless ($fingerprint) {
    die("Get DHCP Fingerprint object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Get DHCP Fingerprint object successful \n";

$session->remove( $fingerprint )
    or die("Remove DHCP Fingerprint object failed",
            $session->status_code() . ":" . $session->status_detail());
print"DHCP Fingerprint object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::FixedAddr - DHCP Fixed Address object.

DESCRIPTION

A Fixed Address is a specific IP address that a DHCP server always assigns when a lease request comes from a particular MAC address of the client.

CONSTRUCTOR

```
 my $fixed_addr = Infoblox::DHCP::FixedAddr -> new(
       ipv4addr                          => $ipv4addr,                  #Required
       agent_circuit_id                  => $circuit_id,                #Optional / Default is undefined
       agent_remote_id                   => $remote_id,                 #Optional / Default is undefined
       always_update_dns                 => "true" | "false",           #Optional / Default is "false"
       bootfile                          => $filename | undef,          #Optional / Default is undefined
       bootserver                        => $ipv4addr | $fqdn | undef,  #Optional / Default is undefined
       client_identifier_prepend_zero    => "true" | "false",           #Optional / Default is "false"
       comment                           => $string,                    #Optional / Default is empty
       configure_for_dhcp                => "true" | "false",           #Optional / Default is "false"
                                                                        # When both the IP address and MAC
address are present, the default value is "true"
                                                                        # Applicable only when adding this
fixed address to a host
       ddns_domainname                   => $string,                    #Optional / Default is empty
       ddns_hostname                     => $string,                    #Optional / Default is empty
       deny_bootp                        => "true" | "false" | undef,   #Optional / Default is undefined

network view
       nextserver                        => $ipv4addr | $fqdn | undef,  #Optional / Default is undefined
       options                           => [$option1, $option2, ...]   #Optional / Default is empty
       override_ddns_domainname          => "true" | "false",           #Optional / Default value is "false"
       pxe_lease_time                    => $time,                      #Optional / Default is empty
       template                          => $string,                    #Optional / Default is undefined
       cli_credentials                   => [$cli1, ...],               #Optional
       override_cli_credentials          => "true" | "false",           #Optional / Default is "false"
       reserved_interface                => $interface,                 #Optional
       device_type                       => $string,                    #Optional
```

```
        device_vendor                   => $string,                     #Optional
        device_location                 => $string,                     #Optional
        device_description              => $string,                     #Optional
        allow_telnet                    => "true" | "false",            #Optional / Default is "false"
        logic_filters                   => [ $filter_name | $filter_obj, ...], # Optional / Default is
undefined
        override_logic_filters          => "true' | 'false",                    # Optional / Default value is
"false"
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DHCP Fixed Address object.

Infoblox::Session->add( )

Use this method to add a DHCP Fixed Address object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
        #Construct a DHCP Fixed Address object
        my $fixed_addr = Infoblox::DHCP::FixedAddr->new(
                "ipv4addr"                          => "10.0.0.5",
                "bootfile"                          => "bootfile",
                "bootserver"                        => "bootserver.com",
                "client_identifier_prepend_zero"    => "true",
                "comment"                           => "add fixed address using uid",
                "ddns_domainname"                   => "ddns.domain.com",
                "ddns_hostname"                     => "ddns.host.domain.com",
                "deny_bootp"                        => "false",
                "dhcp_client_identifier"            => "foo",
                "disable"                           => "false",
                "enable_ddns"                       => "false",
                "match_client"                      => "MAC",
                "network"                           => "10.0.0.0/8",
                "network_view"                      => $nview,
                "nextserver"                        => "3.3.3.3",
                "options"                           => [ $option1,  $option2, $option3,  $option4, $option5,
      $option6 ],
                "pxe_lease_time"                    => "3600",
         );

         #Submit for addition
         my $response = $session->add($fixed_addr)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
        Apply the following attributes to get a specific DHCP Fixed Address object:

          ipv4addr                - Optional. IPV4 address of the fixed address.
          mac                     - Optional. MAC address of the fixed address.
          dhcp_client_identifier  - Optional, DHCP option 61 client identifier.
          network                 - Optional. Network address of the fixed address.
          network_view            - Optional. Network view in which the fixed address is located. By default,
      all network views are searched.
          extattrs                - Optional. A hash reference containing extensible attributes.
          extensible_attributes   - Optional. A hash reference containing extensible attributes.
          v_cluster               - Optional. Discovered VMware cluster name.
          v_datacenter            - Optional. Discovered VMware datacenter name.
          v_host                  - Optional. Discovered VMware server name.
          v_name                  - Optional. Discovered VMware host or virtual machine name.
          v_netadapter            - Optional. Discovered VMware physical network adapter name.
          v_switch                - Optional. Discovered VMware virtual switch name.
          v_type                  - Optional. Discovered VMware entity type (possible values:
      "VirtualMachine", "HostSystem", "VirtualCenter").
```

Examples

```
        #Get DHCP Fixed Address object through the session
```

```
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::FixedAddr",
    mac    => "11:11:11:11:11.11",
);
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::FixedAddr",
    dhcp_client_identifier => "foo",
);
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::FixedAddr",
    ipv4addr     => "10.0.0.4",
    network_view => "default",
);

my @retrieved_objs = $session->get(
   object                => "Infoblox::DHCP::FixedAddr",
   extensible_attributes => { 'Site' => 'Santa Clara' });

 # get FixedAddr by v_type:
 my @retrieved_objs = $session->get(
   object    => 'Infoblox::DHCP::FixedAddr',
   v_type    => 'VirtualMachine');
```

Infoblox::Session->modify( )

Use this method to modify a DHCP Fixed Address object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the pxe_lease_time
$fixed_address->pxe_lease_time("1234");
#Submit modification
my $response = $session->modify( $fixed_address );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP Fixed Address object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP Fixed Address object, and then submit this object for removal.

Example

```
#Get DHCP Fixed Address object through the session
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::FixedAddr",
    mac          => "11:11:11:11:11:11",
    network_view => "default"
);
#Find the desired object from the retrieved list.
my $desired_fixed_addr = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_fixed_addr );
```

Infoblox::Session->search( )

Use this method to search for DHCP Fixed Address object and matching Host object with MAC address in the Infoblox appliance (see below). See Infoblox::Session->search() for parameters and return values.

Note that if the Infoblox library is invoked with the :hostaddress option, only DHCP Fixed Address objects are searched.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
Apply the following attributes to search for a specific DHCP Fixed Address object:

  name          - Optional. Name of the fixed address. If name is passed it implies no_hostaddresses
  ipv4addr      - Optional. IPV4 address of the fixed address (regular expression).
  mac           - Optional. MAC address of the fixed address (regular expression).
  network       - Optional. Network address of the fixed address.
  network_view  - Optional. Network view in which the fixed address is located. By default, all
network views are searched.
  extattrs      - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  v_cluster     - Optional. Discovered VMware cluster name (regular expression).
  v_datacenter  - Optional. Discovered VMware datacenter name (regular expression).
```

```
  v_host        - Optional. Discovered VMware server name (regular expression).
  v_name        - Optional. Discovered VMware host or virtual machine name (regular expression).
  v_netadapter  - Optional. Discovered VMware physical network adapter name (regular expression).
  v_switch      - Optional. Discovered VMware virtual switch name (regular expression).
  v_type        - Optional. Discovered VMware entity type (possible values: "VirtualMachine",
"HostSystem", "VirtualCenter").
  no_hostaddresses - Optional. If specified and set to "true", only Fixed Address objects will be
returned by the search.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# Search for all DHCP Fixed Address objects that are specified in the network "10.0.0.0/8" in the
"default" network view.
my @retrieved_objs = $session->search(
    object       => "Infoblox::DHCP::FixedAddr",
    mac          => "11:11:11:11:11.*",
    network      => "10.0.0.0/8",
    network_view => "default"
);

# Search for all DHCP Fixed Address objects with "Santa Clara" for the "Site" extensible attribute
my @retrieved_objs = $session->search(
    object               => "Infoblox::DHCP::FixedAddr",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);

# search FixedAddr by v_datacenter:
my @retrieved_objs = $session->search(
   object               => 'Infoblox::DHCP::FixedAddr',
   v_datacenter => 'test.*');
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DHCP Fixed Address object.

allow_telnet( )

Use this method to set or retrieve the flag that enables copying SSH credential to TELNET.

Parameter

Specify 'true' to copy SSH credential to TELNET or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $fixed_addr->allow_telnet();
# Modify attribute value
$fixed_addr->allow_telnet('true');
```

bootfile( )

Use this method to set or retrieve the bootfile value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::FixedAddr->bootserver() and Infoblox::DHCP::FixedAddr->nextserver().

Parameter

The name of the file that the client must download. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootfile
my $bootfile = $fixed_addr->bootfile();
#Modify bootfile
$fixed_addr->bootfile("boot_file");
#Un-override bootfile
$fixed_addr->bootfile(undef);
```

agent_circuit_id( )

Use this method to set or retrieve the agent circuit ID of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Use the agent_circuit_id to assign fixed addresses to DHCP clients from whom the member DHCP server receives DHCPDISCOVER and DHCPREQUEST messages that include option 82. To enable the member DHCP server to match the agent circuit ID, set the "match_client" field to "CIRCUIT_ID".

Returns

If you specified a parameter, the method returns true when the modification succeeds and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get agent_circuit_id
my $uid = $fixed_addr->agent_circuit_id();
#Modify agent_circuit_id
$fixed_addr->agent_circuit_id("foo");
```

agent_remote_id( )

Use this method to set or retrieve the agent remote ID of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Use the agent_remote_id to assign fixed addresses to DHCP clients from whom the member DHCP server receives DHCPDISCOVER and DHCPREQUEST messages that include option 82. To enable the member DHCP server to match the agent remote ID, set the "match_client" field to "REMOTE_ID".

Returns

If you specified a parameter, the method returns true when the modification succeeds and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get agent_remote_id
my $uid = $fixed_addr->agent_remote_id();
#Modify agent_remote_id
$fixed_addr->agent_remote_id("foo");
```

always_update_dns( )

Use this method to set or retrieve the always_update_dns flag of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This flag only applies if the fixed address is associated with a Microsoft (r) server. If it is set to "true", the DHCP server will always update DNS, regardless of the requests from the DHCP clients. If this flag is set to false, clients will be allowed to update DNS when they request it.

Parameter

Specify "true" to set the always_update_dns flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get always_update_dns
my $always_update_dns = $fixed_addr->always_update_dns();
#Modify always_update_dns
$fixed_addr->always_update_dns("false");
```

bootserver( )

Use this method to set or retrieve the bootserver of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::FixedAddr->bootfile() and Infoblox::DHCP::FixedAddr->nextserver().

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootserver
my $bootserver = $fixed_addr->bootserver();
#Modify bootserver
$fixed_addr->bootserver("bootserver2.com");
#Un-override bootserver
$fixed_addr->bootserver(undef);
```

client_identifier_prepend_zero( )

Use this method prepend "\000" to the dhcp-client-identifier of a fixed address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

When you set the client_identifier_prepend_zero parameter to "true", it prefixes a 0 (zero) to the DHCP client identifier whenever option 61 is used to assign fixed addresses. The following is an excerpt from "man dhcp-options":

Please be aware that some DHCP clients, when configured with client identifiers that are ASCII text, will prepend a zero to the ASCII text. So you may need to write:

```
option dhcp-client-identifier "\000foo"
```

rather than:

```
option dhcp-client-identifier "foo".
```

Returns

If you specified a parameter, the method returns true when the modification succeeds and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get client_identifier_prepend_zero
my $client_identifier_prepend_zero = $fixed_addr->client_identifier_prepend_zero();
#Modify dhcp_client_identifier
$fixed_addr->client_identifier_prepend_zero("true");
```

cli_credentials( )

Use this method to set or retrieve the discovery CLI credentials.

Setting this method to a defined value implicitly sets the override_cli_credentials method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_cli_credentials attribute to "false".

Note that when cli_credentials is set to a defined value and override_cli_credentials is set to "false", the last operation takes precedence. Thus the sequence $fixed_addr->cli_credentials([$cli]); $fixed_addr->override_cli_credentials("false"); will set override_cli_credentials to "false", and the sequence $fixed_addr->override_cli_credentials("false"); $fixed_addr->cli_credentials([$cli]); will result in override_cli_credentials="true".

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::CLICredential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get cli_credentials
my $cli_credentials = $fixed_addr->cli_credentials();
#Modify cli_credentials
$fixed_addr->cli_credentials([$cli1, $cli2]);
```

comment( )

Use this method to set or retrieve the descriptive comment of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $fixed_addr->comment();
#Modify comment
$fixed_addr->comment("Modified DHCP Fixed Address object comment");
```

configure_for_dhcp( )

Use this method to set or retrieve the configure_for_dhcp flag of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the configure_for_dhcp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get configure_for_dhcp
my $configure_for_dhcp = $fixed_addr->configure_for_dhcp();
#Modify configure_for_dhcp
$fixed_addr->configure_for_dhcp("true");
```

cloud_info( )

Use this method to retrieve cloud API related information for the Infoblox::DHCP::FixedAddr object.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $object->cloud_info();
```

ddns_domainname( )

Use this method to set or retrieve the DDNS domain name value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_dddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

Specify the DDNS domain name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the DDNS domain name
my $ddns_domainname = $fixed_addr->ddns_domainname();
#Modify the DDNS domain name
$fixed_addr->ddns_domainname("ddns.domain.com");
```

ddns_hostname( )

Use this method to set or retrieve the DDNS host name value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the DDNS host name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the DDNS host name
my $ddns_hostname = $fixed_addr->ddns_hostname();
#Modify the DDNS host name
$fixed_addr->ddns_hostname("host.ddns.domain.com");
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is undefined which indicates that this attribute inherits the upper-level setting

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $fixed_addr->deny_bootp();
#Modify deny_bootp
$fixed_addr->deny_bootp("true");
```

device_description( )

Use this method to set or retrieve the description of the discovery device.

Parameter

The device description in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_description
my $device_description = $fixed_addr->device_description();
#Modify device_description
$fixed_addr->device_description('example');
```

device_location( )

Use this method to set or retrieve the location of the discovery device.

Parameter

The device location in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_location
my $device_location = $fixed_addr->device_location();
#Modify device_location
$fixed_addr->device_location('example');
```

device_type( )

Use this method to set or retrieve the type of the discovery device.

Parameter

The device type in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_type
my $device_type = $fixed_addr->device_type();
#Modify device_type
$fixed_addr->device_type('example');
```

device_vendor( )

Use this method to set or retrieve the vendor name of the discovery device.

Parameter

The device vendor name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_vendor
my $device_vendor = $fixed_addr->device_vendor();
#Modify device_vendor
$fixed_addr->device_vendor('example');
```

dhcp_client_identifier( )

Use this method to set or retrieve the dhcp-client-identifier value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Use the dhcp_client_identifier or uid to assign fixed addresses if the DHCP clients send option 61. A DHCP client identifier can be a string or a MAC address. Set the "match_client" field to "CLIENT_IDENTIFIER" for fixed addresses to use the dhcp_client_identifier instead of the mac_address.

Returns

If you specified a parameter, the method returns true when the modification succeeds and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dhcp_client_identifier
my $uid = $fixed_addr->dhcp_client_identifier();
#Modify dhcp_client_identifier
$fixed_addr->dhcp_client_identifier("foo");
or
$fixed_addr->dhcp_client_identifier("1:11::11::11::11::11::12");
```

disable( )

Use this method to set or retrieve the disable flag of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $fixed_addr->disable();
#Modify disable
$fixed_addr->disable("true");
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $fixed_addr->discover_now_status();
```

discovered_data( )

Use this method to retrieve the discovered data of a DHCP Fixed Address object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Data object.

Example

```
#Get discovered_data value
my $discovered_data = $object->discovered_data();
```

discovered_mac( )

Use this method to retrieve the discovered MAC address of a DHCP Fixed Address object.

Parameter

none

Returns

The method returns the discovered MAC address.

Example

```
#Get discovered_mac
my $discovered_mac = $fixed_addr->discovered_mac();
```

discovered_name( )

Use this method to retrieve the discovered name of a DHCP Fixed Address object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
my $discovered_name = $fixed_addr->discovered_name();
```

discoverer( )

Use this method to retrieve the discoverer of a DHCP Fixed Address object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $fixed_addr->discoverer();
```

enable_ddns( )

Use this method to set or retrieve the enable_ddns flag of a DHCP Fixed Address object.

If enable_ddns value is specified as "true", then the A and PTR records corresponding to the Fixed Address object will be placed on the DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_ddns flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ddns
my $enable_ddns = $fixed_addr->enable_ddns();
#Modify enable_ddns
$fixed_addr->enable_ddns("true");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Fixed Address object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $fixed_addr->extattrs();
#Modify extattrs
$fixed_addr->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Fixed Address object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $fixed_addr->extensible_attributes();
#Modify extensible attributes
$fixed_addr->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

first_discovered( )

Use this method to retrieve the date and time that the DHCP Fixed Address object was first discovered.

Parameter

none

Returns

The method returns the date and time that the DHCP Fixed Address object was first discovered.

Example

```
#Get first_discovered
my $first_discovered = $fixed_addr->first_discovered();
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a DHCP Fixed address object. If this flag is set to false all the defined DHCP options will be returned to the client.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate/unset it. The default value is false which indicates that this attribute inherit the member level setting..

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $fixed_addr->ignore_dhcp_option_list_request();
# Un-override ignore_dhcp_option_list_request
$fixed_addr->ignore_dhcp_option_list_request(undef);
# Modify ignore_dhcp_option_list_request
$fixed_addr->ignore_dhcp_option_list_request("true");
```

ipv4addr( )

Use this method to set or retrieve the ipv4addr value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $fixed_addr->ipv4addr();
#Modify ipv4addr
$fixed_addr->ipv4addr("10.0.0.5");
```

is_invalid_mac( )

Use this method to retrieve the flag used to indicate whether an invalid MAC address is used. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get is_invalid_mac value
my $is_invalid_mac = $fixed_addr->is_invalid_mac();
```

last_discovered( )

Use this method to retrieve the time this object was last seen by a discovery job.

The default value for this field is empty.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get last_discovered
my $last_discovered = $fixed_addr->last_discovered();
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Fixed Address.

Filters are used to screen address assignments for the DHCP Fixed Address if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $fixed_addr->logic_filters();
#Modify logic_filters
$fixed_addr->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an Infoblox::DHCP::Filter::MAC,
Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

mac( )

```
Use this method to set or retrieve the MAC address value of a DHCP Fixed Address object.
```

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

MAC Address of the DHCP Fixed address object. Format for the hexadecimal strings for MAC addresses and vendor prefixes with colons or dashes. Both of the following formats are acceptable: 11:11:11:11:11:11 and 11-11-11-11-11-11.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mac
my $mac = $fixed_addr->mac();
#Modify mac
$fixed_addr->mac("11::11::11::11::11::11::12");
```

match_client( )

Use this method to set or retrieve the match_client value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

```
    match_client "MAC": The fixed IP address is leased to the matching MAC address.

    match_client "CLIENT_IDENTIFIER": The fixed IP address is leased to the matching DHCP client
identifier

    match_client "RESERVED": The fixed IP address is reserved for later use with a MAC address that
only has zeros.

    match_client "CIRCUIT_ID": The fixed IP address is leased to the DHCP client with a matching
circuit ID. Note that
                  the "agent_circuit_id" field must be set in this case.

    match_client "REMOTE_ID": The fixed IP address is leased to the DHCP client with a matching
remote ID. Note that
                  the "agent_remote_id" field must be set in this case.
```

Returns

```
    If you specified a parameter, the method returns true when the modification succeeds, and returns
false when the operation fails.

    If you did not specify a parameter, the method returns the attribute value.
```

Example

```
#Get match_client
my $match_client = $fixed_addr->match_client();
#Modify match_client
$fixed_addr->match_client("CLIENT_IDENTIFIER");
```

member( )

Use this method to set or retrieve the Microsoft server associated with this fixed address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a defined Infoblox::DHCP::MSServer object. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member
my $ref_member = $dhcp_fixedaddr->member();
#Modify member
$dhcp_fixedaddr->member($member1); #$member1 is an Infoblox::DHCP::MSServer object
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $dhcp_fixedaddr->ms_ad_user_data();
```

name( )

```
Use this method to set or retrieve the name of a DHCP Fixed Address object.
```

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A string specifying the name of the fixed address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $fixed_addr->name();
#Modify name
$fixed_addr->name("fxname");
```

netbios( )

Use this method to retrieve the name in the NetBIOS reply that responded to a NetBIOS query.

Returns

The method returns the attribute value.

Example

```
#Get netbios
my $netbios = $fixed_addr->netbios();
```

ms_options( )

Use this method to set or retrieve the Microsoft server custom DHCP options associated with this DHCP fixed address.

Note: You can set only options that are specified in both the Microsoft server and NIOS option definitions. Options that are not common to both the Microsoft server and NIOS cannot be modified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::MSOption objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $ref_options = $dhcp_fixedaddr->ms_options();
#Modify options
$dhcp_fixedaddr->ms_options([$option12]); #$option12 is an Infoblox::DHCP::MSOption object
```

network( )

Use this method to retrieve the network value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An network is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points followed by prefix (example: 1.0.0.0/8).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network
my $network = $fixed_addr->network();
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $fixed_addr->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the IP address of the network device.

Example

```
#Get network_component_ip
my $network_component_ip = $fixed_addr->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the network device name.

Example

```
#Get network_component_name
my $network_component_name = $fixed_addr->network_component_name();
```

network_component_port_description( )

Use this method to retrieve the description of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the description of the port on the network device.

Example

```
#Get network_component_port_description
my $network_component_port_description = $fixed_addr->network_component_port_description();
```

network_component_port_name( )

Use this method to retrieve the name of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the name of the port on the network device.

Example

```
#Get network_component_port_name
my $network_component_port_name = $fixed_addr->network_component_port_name();
```

network_component_port_number( )

Use this method to retrieve the number of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the network device port number.

Example

```
#Get network_component_port_number
my $network_component_port_number = $fixed_addr->network_component_port_number();
```

network_component_type( )

Use this method to retrieve the type of the network device that is connected to DHCP Fixed Address object.

Parameter

none

Returns

The method returns the network device type.

Example

```
#Get network_component_type
my $network_component_type = $fixed_addr->network_component_type();
```

network_view( )

Use this method to set or retrieve the network view of the DHCP fixed address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the fixed address is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $fixed_addr->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$fixed_addr->network_view($nview);
```

nextserver( )

Use this method to set or retrieve the nextserver value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::FixedAddr->bootfile() and Infoblox::DHCP::FixedAddr->bootserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nextserver
my $nextserver = $fixed_addr->nextserver();
#Modify nextserver
$fixed_addr->nextserver("3.3.3.4");
#Un-override nextserver
$fixed_addr->nextserver(undef);
```

options( )

Use this method to set or retrieve the options of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

See Infoblox::DHCP::Option for parameters and methods available for this object.

Parameter

Options describe network configuration settings and various services available on the network. These options occur as variable-length fields at the end of DHCP messages.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $fixed_addr->options();
#Modify options
$fixed_addr->options([$option1, $option2]);
```

os( )

Use this method to retrieve the operating system associated with this fixed address.

Returns

The method returns the attribute value.

Example

```
#Get os
my $os = $fixed_addr->os();
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP Fixed Address is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$fixed_addr->override_ddns_domainname( );
#Modifying override_ddns_domainname
$fixed_addr->override_ddns_domainname("true");
```

override_cli_credentials( )

The override_cli_credentials attribute controls whether the cli_credentials value in the object is used, instead of the grid default.

The override_cli_credentials attribute can be specified explicitly. It is also set implicitly when cli_credentials is set to a defined value.

Parameter

Specify "true" to set the override_cli_credentials flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $fixed_addr->override_cli_credentials();
# Modify attribute value
$fixed_addr->override_cli_credentials('true');
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value of the DHCP Fixed Address is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$fixed_addr->override_logic_filters( );
#Modifying override_logic_filters
$fixed_addr->override_logic_filters("true");
```

port_duplex( )

Use this method to retrieve the duplex setting of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the port duplex setting. Returned values, if any, are one of the following:

```
Full
Half
```

Example

```
#Get port_duplex
my $port_duplex = $fixed_addr->port_duplex();
```

port_link_status( )

Use this method to retrieve the link status of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the network device port link status. Returned values, if any, are one of the following:

```
Connected
Not Connected
Unknown
```

Example

```
#Get port_link_status
my $port_link_status = $fixed_addr->port_link_status();
```

port_speed( )

Use this method to retrieve the speed of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the network device port speed. Returned values, if any, are one of the following:

```
10M
100M
1G
10G
100G
Unknown
```

Example

```
#Get port_speed
my $port_speed = $fixed_addr->port_speed();
```

port_status( )

Use this method to retrieve the status of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the network device port status. Returned values, if any, are one of the following:

```
Up
Down
Unknown
```

Example

```
#Get port_status
my $port_status = $fixed_addr->port_status();
```

port_vlan_description( )

Use this method to retrieve the VLAN description of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the VLAN description of the network device port.

Example

```
#Get port_vlan_description
my $port_vlan_description = $fixed_addr->port_vlan_description();
```

port_vlan_name( )

Use this method to retrieve the VLAN name of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the network device port VLAN name.

Example

```
#Get port_vlan_name
my $port_vlan_name = $fixed_addr->port_vlan_name();
```

port_vlan_number( )

Use this method to retrieve the VLAN number of the network device port that is connected to the DHCP Fixed Address object.

Parameter

none

Returns

The method returns the port VLAN number.

Example

```
#Get port_vlan_number
my $port_vlan_number = $fixed_addr->port_vlan_number();
```

pxe_lease_time( )

Use this method to set or retrieve the pxe_lease_time value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter appropriate values in the Days, Hours, Mins and Secs fields. User can specify the duration of time it takes a host to connect to a boot server, such as a TFTP server, and download the file it needs to boot.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get pxe_lease_time
my $pxe_lease_time = $fixed_addr->pxe_lease_time();
#Modify pxe_lease_time
$fixed_addr->pxe_lease_time("369");
```

reserved_interface( )

Use this method to set or retrieve the reserved discovery interface.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get reserved_interface
my $reserved_interface = $fixed_addr->reserved_interface();
#Modify reserved_interface
$fixed_addr->reserved_interface($interface);
```

template( )

Use this method to set or retrieve the fixed address template name for a DHCP Fixed Address object.

Template is the name of a DHCP Fixed Address template which will be used to create the DHCP Fixed Address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid name in sting format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

The template parameter can be used to only add a new DHCP Fixed Address and cannot be used during object modify or returned during object get.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get template
my $template = $fixed_addr->template();
#Modify template
$fixed_addr->template("Template_Name");
```

v_cluster( )

Use this method to retrieve the name of the VMware cluster associated with the DHCP Fixed Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware cluster name. The default value is an empty string.

Example

```
#Get v_cluster
my $v_cluster = $fixed_addr->v_cluster();
```

v_datacenter( )

Use this method to retrieve the name of the VMware datacenter associated with the DHCP Fixed Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware datacenter name. The default value is an empty string.

Example

```
#Get v_datacenter
my $v_datacenter = $fixed_addr->v_datacenter();
```

v_host( )

Use this method to retrieve the name of the VMware host associated with the DHCP Fixed Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware host name. The default value is an empty string.

Example

```
#Get v_host
my $v_host = $fixed_addr->v_host();
```

v_name( )

Use this method to retrieve the name of the VMware entity associated with the DHCP Fixed Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware entity name. The default value is an empty string.

Example

```
#Get v_name
my $v_name = $fixed_addr->v_name();
```

v_netadapter( )

Use this method to retrieve the name of the physical network adapter through which the VMware entity is connected to the appliance. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the network adapter name. The default value is an empty string.

Example

```
#Get v_netadapter
my $v_netadapter = $fixed_addr->v_netadapter();
```

v_switch( )

Use this method to retrieve the name of the virtual switch through which the VMware entity is connected to the appliance. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the virtual switch name. The default value is an empty string.

Example

```
#Get v_switch
my $v_switch = $fixed_addr->v_switch();
```

v_type( )

Use this method to retrieve the type of VMware entity associated with the DHCP Fixed Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware entity type. The default value is an empty string. The returned value, if any, can be one of the following:

```
VirtualMachine
HostSystem
VirtualCenter
```

Example

```
#Get v_type
my $v_type = $fixed_addr->v_type();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP Fixed Address object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
```

```
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a network object
my $network = Infoblox::DHCP::Network->new(
                                          "network" => "10.0.0.0/8",
                                         );
unless($network) {
     die("Construct Network object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network object created successfully\n";

$session->add($network)
    or die("Add network failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Network added successfully\n";

my $option1 = Infoblox::DHCP::Option->new(
                                          "name"  => "lease-time",
                                          "value" => "50"
                                         );

NAME

Infoblox::DHCP::FixedAddrTemplate - DHCP Fixed Address template object.

DESCRIPTION

A fixed address template works as a 'cookie cutter' and can be used to create a real fixed address object in a quick and consistant way. A Fixed address object created from a fixed address template will inherit most properties defined in fixed address template object so most of the fixed address template properties are the same as the fixed address object properties.

CONSTRUCTOR

```
 my $fixed_addr_template = Infoblox::DHCP::FixedAddrTemplate -> new(
       name                              => $string,                        #Required
       number_of_addresses               => $num | undef,                   #Optional / Default is undefined
       offset                            => $num | undef,                   #Optional / Default is undefined
       bootfile                          => $filename | undef,              #Optional / Default is undefined
       bootserver                        => $ipv4addr | $fqdn | undef,      #Optional / Default is undefined
       comment                           => $string,                        #Optional / Default is empty
       deny_bootp                        => "true" | "false" | undef,       #Optional / Default is undefined
       enable_ddns                       => "true" | "false",               #Optional / Default is false
       ddns_domainname                   => $string | undef,                #Optional / Default is undefined
       ddns_hostname                     => $string | undef,                #Optional / Default is undefined
       extattrs                          => { $string => $extattr, ... },      #Optional / Default is
undefined
       extensible_attributes             => { $string => $string | $num, $string => [ $string | $num, ... ],
... } #Optional / Default is undefined

       ignore_dhcp_option_list_request   => "true" | "false" | undef,       #Optional / Default is false
       nextserver                        => $ipv4addr | $fqdn | undef,      #Optional / Default is undefined
       options                           => [$option1, $option2, ...]       #Optional / Default is empty
```

```
        override_ddns_domainname          => "true" | "false",            #Optional / Default value is
"false"
        pxe_lease_time                    => $time,                       #Optional / Default is empty
        logic_filters                     => [ $filter_name | $filter_obj, ...], # Optional / Default is
undefined
        override_logic_filters            => "true' | 'false",                  # Optional / Default value
is "false"
         );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

MODULE METHODS

The following functions are available to be applied to a DHCP fixed address template object.

Infoblox::DHCP::NetworkTemplate-> fixed_address_templates( )

Use this function to specify a fixed address template at network template on the Infoblox appliance. See Infoblox::DHCP::NetworkTemplate->fixed_address_templates() for parameters and return values.

Example

```
        #Create the Network Template object with fixed address template
         my $template = Infoblox::DHCP::Template->new(
           name                    => "custom_fa_template"
         );
         my $network_template = Infoblox::DHCP::NetworkTemplate->new(
           name                    => "custom_network_template",
           comment                 => "add network",
           fixed_address_templates => [$template]
         );
```

SESSION METHODS

This section describes all the methods in Infoblox::Session module that can be applied to a DHCP Fixed Address template object.

Infoblox::Session->add( )

Use this method to add a DHCP Fixed Address template object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
        #Construct a DHCP Fixed Address template object
        my $fixed_addr_template = Infoblox::DHCP::FixedAddrTemplate->new(
               "name"                  => "custom_fa_template",
               "offset"                => "10",
               "number_of_addresses"   => "1",
               "bootfile"              => "bootfile",
               "bootserver"            => "bootserver.com",
               "comment"               => "add fixed address",
               "deny_bootp"            => "false",
               "enable_ddns"           => "false",
               "nextserver"            => "3.3.3.3",
               "options"               => [ $option1,  $option2 ],
               "pxe_lease_time"        => "3600",
        );

        #Submit for addition
        my $response = $session->add($fixed_addr_template);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
        Apply the following attributes to get a specific DHCP Fixed Address template object:

        name - Optional. The name of the Fixed address template.
        extattrs     - Optional. A hash reference containing extensible attributes.
        extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Examples

```
#Get DHCP Fixed Address template object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::FixedAddrTemplate",
    name   => "custom_fa_template",
);

my @retrieved_objs = $session->get(
  object               => "Infoblox::DHCP::FixedAddrTemplate",
  extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a DHCP Fixed Address template object:

name    - Optional. The name of the fixed address template (regular expression).
comment - Optional. The comment of the fixed address template (regular expression).
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
#Search DHCP Fixed Address template object through the session
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::FixedAddrTemplate",
    name    => "custom_fa_template",
    comment => ".*",
);

#Search for DHCP Fixed Address template objects defining "Santa Clara" for "Site" extensible attribute
my @retrieved_objs = $session->search(
    object               => "Infoblox::DHCP::FixedAddrTemplate",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP Fixed Address template object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the pxe_lease_time
$fixed_addr_templateess->pxe_lease_time("1234");
#Submit modification
my $response = $session->modify( $fixed_addr_templateess );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP Fixed Address template object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` to retrieve the specific DHCP Fixed Address template object, and then submit this object for removal.

Example

```
#Get DHCP Fixed Address template object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::FixedAddrTemplate",
    name   => "custom_fa_template",
);
#Find the desired object from the retrieved list.
my $desired_fixed_addr_template = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_fixed_addr_template );
```

METHODS

This section describes all the methods that can be used to set and retrieve the attribute values of a DHCP Fixed Address template object.

bootfile( )

Use this method to set or retrieve the bootfile value of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::FixedAddrTemplate->bootserver() and Infoblox::DHCP::FixedAddrTemplate->nextserver().

Parameter

The name of the file that the client must download. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootfile
my $bootfile = $fixed_addr_template->bootfile();
#Modify bootfile
$fixed_addr_template->bootfile("boot_file");
#Un-override bootfile
$fixed_addr_template->bootfile(undef);
```

bootserver( )

Use this method to set or retrieve the bootserver of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::FixedAddrTemplate->bootfile() and Infoblox::DHCP::FixedAddrTemplate->nextserver().

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootserver
my $bootserver = $fixed_addr_template->bootserver();
#Modify bootserver
$fixed_addr_template->bootserver("bootserver2.com");
#Un-override bootserver
$fixed_addr_template->bootserver(undef);
```

comment( )

Use this method to set or retrieve the descriptive comment of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $fixed_addr_template->comment();
#Modify comment
$fixed_addr_template->comment("Modified DHCP Fixed Address template object comment");
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $fixed_addr_template->deny_bootp();
#Modify deny_bootp
$fixed_addr_template->deny_bootp("true");
```

enable_ddns( )

Use this method to set or retrieve the enable_ddns flag of a DHCP Fixed Address template object. If enable_ddns value is specified as "true", then the A and PTR records corresponding to the Fixed Address template object will be placed on the DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_ddns flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ddns
my $enable_ddns = $fixed_addr_template->enable_ddns();
#Modify enable_ddns
$fixed_addr_template->enable_ddns("true");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Fixed Address template object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $fixed_addr_template->extattrs();
#Modify extattrs
$fixed_addr_template->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Fixed Address template object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $fixed_addr_template->extensible_attributes();
#Modify extensible attributes
$fixed_addr_template->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_dddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

Desired name for the dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $fixed_addr->ddns_domainname();
#Modify ddns_domainname
$fixed_addr->ddns_domainname("test_domain.com");
```

ddns_hostname( )

Use this method to set or retrieve the ddns_hostname value of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name for the dynamic DNS host name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_hostname
my $ddns_hostname = $fixed_addr->ddns_hostname();
#Modify ddns_hostname
$fixed_addr->ddns_hostname("test_host");
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a DHCP fixed address teplate object. If this flag is set to false all the defined DHCP options will be returned to the client. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate it. The default value is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $fixed_addr_template->ignore_dhcp_option_list_request();
# Modify ignore_dhcp_option_list_request
$fixed_addr_template->ignore_dhcp_option_list_request("true");
# Un-override ignore_dhcp_option_list_request
$fixed_addr_template->ignore_dhcp_option_list_request(undef);
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Fixed Address Template.

Filters are used to screen address assignments for the DHCP Fixed Address Template if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $fixed_addr_template->logic_filters();
#Modify logic_filters
$fixed_addr_template->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an
Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

name( )

Use this method to set or retrieve the name of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the fixed address template in string format with a maximum of 64 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.
If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $fixed_address_template->name();
#Modify name
$fixed_address_template->name("custom_fa_template");
```

nextserver( )

Use this method to set or retrieve the nextserver value of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::FixedAddrTemplate->bootfile() and Infoblox::DHCP::FixedAddrTemplate->bootserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nextserver
my $nextserver = $fixed_addr_template->nextserver();
#Modify nextserver
$fixed_addr_template->nextserver("3.3.3.4");
#Un-override nextserver
$fixed_addr_template->nextserver(undef);
```

number_of_addresses( )

Use this method to set or retrieve the number of addresses in a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of addresses in this fixed address template.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get number_of_addresses
my $number_of_addresses = $fixed_address_template-> number_of_addresses();
#Modify number_of_addresses
$fixed_address_template->number_of_addresses("10");
```

offset( )

Use this method to set or retrieve the address offset of a Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The address offset of this fixed address template. The offset is calculated from the start address of network template to which the fixed address template is assigned to. For example, if offset is set to 10 and number_of_addresses is set to 10, and network is set to 10.0.0.0/8, then there will be 10 fixed address object created and start address will be 10.0.0.10 and end address will be 10.0.0.20.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get offset
my $offset = $fixed_address_template->offset();
#Modify offset
$fixed_address_template->offset("10");
```

options( )

Use this method to set or retrieve the options of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

See Infoblox::DHCP::Option for parameters and methods available for this object.

Parameter

Options describe network configuration settings and various services available on the network. These options occur as variable-length fields at the end of DHCP messages.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $fixed_addr_template->options();
#Modify options
$fixed_addr_template->options([$option1, $option2]);
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP Fixed Address is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$fixed_addr_template->override_ddns_domainname( );
#Modifying override_ddns_domainname
$fixed_addr_template->override_ddns_domainname("true");
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value of the DHCP Fixed Address Template is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$fixed_addr_template->override_logic_filters( );
#Modifying override_logic_filters
$fixed_addr_template->override_logic_filters("true");
```

pxe_lease_time( )

Use this method to set or retrieve the pxe_lease_time value of a DHCP Fixed Address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter appropriate values in the Days, Hours, Mins and Secs fields. User can specify the duration of time it takes a host to connect to a boot server, such as a TFTP server, and download the file it needs to boot.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get pxe_lease_time
my $pxe_lease_time = $fixed_addr_template->pxe_lease_time();
#Modify pxe_lease_time
$fixed_addr_template->pxe_lease_time("369");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify, and remove. Also, this sample includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $option1 = Infoblox::DHCP::Option->new(
                                          "name"  => "fqdn",
                                          "value" => "mydomain.com"
                                         );
unless($option1) {
     die("Construct option1 object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "option1 object created successfully\n";

my $option2 = Infoblox::DHCP::Option->new(
                                          "name"     => "merit-dump",
                                           "value"   => "sometextdump",
                                         );
unless($option2) {
     die("Construct option2 object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "option2 object created successfully\n";
```

#Create a DHCP Fixed Address template object

```
#Create a DHCP Fixed Address template object
my $fixed_addr_template = Infoblox::DHCP::FixedAddrTemplate->new(
    "name"                  => "custom_fa_template",
    "offset"                => "10",
    "number_of_addresses"   => "1",
    "comment"               => "add fixed address template",
    "enable_ddns"           => "TRUE",
    "ddns_domainname"       => "test_domain.com",
```

```
    "ddns_hostname"          => "test_host",
    "pxe_lease_time"         => "3600",
    "bootserver"             => "someserver.com",
    "nextserver"             => "3.3.3.3",
    "bootfile"               => "bootfile.com",
    "options"                => [ $option1, $option2 ],
);
unless($fixed_addr_template) {
     die("Construct Fixed Address template failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Fixed Address template object created successfully\n";

#Verify if the DHCP Fixed Address templateexists in the Infoblox appliance
my $object = $session->get(
       object => "Infoblox::DHCP::FixedAddrTemplate",
       name   => "custom_fa_template"
);

unless ($object) {
   print "Fixed Address template does not exist on server, safe to add the fixed address template\n";
   $session->add($fixed_addr_template)
      or die("Add Fixed Address template failed: ",
             $session->status_code() . ":" . $session->status_detail());
}
print "DHCP Fixed Address template added successfully\n";
```

#Search a DHCP Fixed Address template object

```
#Search DHCP Fixed Address template object through the session
my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::FixedAddrTemplate",
    name   => "custom_fa_template",
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Search Fixed Address template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search Fixed Address template object found at least 1 matching entry\n";
```

#Get and modify a DHCP Fixed Address template object

```
#Get DHCP Fixed Address template object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::FixedAddrTemplate",
    name   => "custom_fa_template",
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Get Fixed Address template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Fixed Address template object found at least 1 matching entry\n";

#Modify one of the attributes of the obtained Fixed Address template object
$object->pxe_lease_time("1234");

#Un-override bootfile
$object->bootfile(undef);

#Un-override bootserver
$object->bootserver(undef);

#Un-override nextserver
$object->nextserver(undef);

#Apply the changes
$session->modify($object)
  or die("Modify Fixed Address template failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "DHCP Fixed Address template added successfully\n";
```

#Create the Network Template object with fixed address template

```
my $template = Infoblox::DHCP::Template->new(
    name => "custom_fa_template",
);

my $network_template = Infoblox::DHCP::NetworkTemplate->new(
    name    => "custom_network_template",
    comment => "add network",
    fixed_address_templates => [$template]
);

unless($network_template) {
       die("Construct Network template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "Network template object created successfully\n";

#Add the Network template object into the Infoblox appliance through a session
my $resp = $session->add($network_template)
or die("Add Network object failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "Network template object added to Infoblox appliance successfully\n";
```

#Remove a Fixed Address template object

```
#Remove a Network Template object
$session->remove($network_template)
    or die("Remove Network Template template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "Network Template object removed successfully \n";

#Get Fixed Address template object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::FixedAddrTemplate",
    name   => "custom_fa_template",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get Fixed Address template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Fixed Address template object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove Fixed Address template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "Fixed Address template object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::HostAddr - DHCP Host Address object.

DESCRIPTION

A Host Address is an object used to specify addresses in a DNS Host object.

CONSTRUCTOR

```
my $host_addr = Infoblox::DHCP::HostAddr -> new(
      ipv4addr                          => $ipv4addr,                  #Required
      bootfile                          => $filename,                  #Optional / Default is undefined
      bootserver                        => $ipv4addr | $fqdn,          #Optional / Default is undefined
      configure_for_dhcp                => "true" | "false",           #Optional / Default is "false"
      deny_bootp                        => "true" | "false",           #Optional / Default is "false"
      dhcp_client_identifier            => $string,                    #Optional / Default is empty
      enable_pxe_lease_time             => "true" | "false",           #Optional / Default is "false"
      ignore_client_requested_options   => "true" | "false",           #Optional / Default is "false"
      mac                               => $mac_addr,                  #Optional / Default is empty
      match_client                      => $string,                    #Optional / Default is "MAC"
                                                                       #Possible values are:
                                                                       #
"MAC","CLIENT_IDENTIFIER","RESERVED",
                                                                       # "CIRCUIT_ID", "REMOTE_ID"
      nextserver                        => $ipv4addr | $fqdn | undef,  #Optional / Default is undefined
      options                           => [$option1, $option2, ...]   #Optional / Default is empty
      override_bootfile                 => "true" | "false",           #Optional / Default is "false"
      override_bootserver               => "true" | "false",           #Optional / Default is "false"
      override_deny_bootp               => "true" | "false",           #Optional / Default is "false"
      override_ignore_client_requested_options => "true" | "false",    #Optional / Default is "false"
      override_nextserver               => "true" | "false",           #Optional / Default is "false"
      override_options                  => "true" | "false",           #Optional / Default is "false"
      override_pxe_lease_time           => "true" | "false",           #Optional / Default is "false"
      pxe_lease_time                    => $time,                      #Optional / Default is empty
      use_for_ea_inheritance            => "true" | "false",           #Optional / Default is "false"
      reserved_interface                => $interface,                 #Optional
      logic_filters                     => [ $filter_name | $filter_obj, ...], # Optional / Default is
undefined
      override_logic_filters            => "true' | 'false",                  # Optional / Default value is
"false"
 );
```

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DHCP Host Address object.

Infoblox::DNS::Host->ipv4addrs( )

Use this function to specify the addresses associated with the Host record. See Infoblox::DNS::Host->ipv4addrs() for parameters and return values.

Example

```
      #Construct a Host Address object
      my $h1 = Infoblox::DHCP::HostAddr->new(
                  ipv4addr  => "10.0.0.1"
      );

      # Configure an address in the Host record object
      $host->ipv4addrs([$h1]);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
    Apply the following attributes to get a specific DHCP Host Address object:

     ipv4addr                - Optional. IPV4 address of the host address.
     mac                     - Optional. MAC address of the host address.
     host                    - Optional, the name of the host to which this address belongs.

     discovered_mac                          - Optional. Discovered MAC address.
     discovered_name                         - Optional. Discovered name.
     discoverer                              - Optional. Discoverer name.
     first_discovered                        - Optional. Time of the first discovery.
     last_discovered                         - Optional. Time of the last discovery.
     netbios                                 - Optional. Discovered NetBIOS name.
     network_component_description           - Optional. Discovered network component description.
     network_component_ip                    - Optional. Discovered network component IP address.
     network_component_name                  - Optional. Discovered network component name.
     network_component_port_description      - Optional. Discovered network component port description.
     network_component_port_name             - Optional. Discovered network component port name.
     network_component_port_number           - Optional. Discovered network component port number.
     network_component_type                  - Optional. Discovered network component type.
     os                                      - Optional. Discovered OS.
     port_duplex                             - Optional. Discovered port duplex settings.
     port_link_status                        - Optional. Discovered port link status.
     port_speed                              - Optional. Discovered port speed settings.
     port_status                             - Optional. Discovered port status settings.
     port_vlan_description                   - Optional. Discovered port VLAN description.
     port_vlan_name                          - Optional. Discovered port VLAN name.
     port_vlan_number                        - Optional. Discovered port VLAN number.
     v_cluster                               - Optional. Discovered VMware cluster name.
     v_datacenter                            - Optional. Discovered VMware datacenter name.
     v_host                                  - Optional. Discovered VMware server name.
     v_name                                  - Optional. Discovered VMware host or virtual machine name.
     v_netadapter                            - Optional. Discovered VMware physical network adapter name.
     v_switch                                - Optional. Discovered VMware virtual switch name.
     v_type                                  - Optional. Discovered VMware entity type (possible values:
"VirtualMachine", "HostSystem", "VirtualCenter").
```

Examples

```
#Get DHCP Host Address object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::HostAddr",
    mac    => "11:11:11:11:11.11",
);

# get HostAddr by v_type:
my @retrieved_objs = $session->get(
   object    => 'Infoblox::DHCP::HostAddr',
   v_type    => 'VirtualMachine');
```

Infoblox::Session->modify( )

Use this method to modify a DHCP Host Address object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the pxe_lease_time
$host_address->pxe_lease_time("1234");
#Submit modification
my $response = $session->modify( $host_address );
```

Infoblox::Session->search( )

Use this method to search for DHCP Host Address object. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
    Apply the following attributes to search for a specific DHCP Host Address object:

     ipv4addr                - Optional. IPV4 address of the host address (regular expression).
     mac                     - Optional. MAC address of the host address (regular expression).
     host                    - Optional, the name of the host to which this address belongs (regular
expression).

     discovered_mac                          - Optional. Discovered MAC address.
     discovered_name                         - Optional. Discovered name (regular expression).
     discoverer                              - Optional. Discoverer name (regular expression).
     first_discovered                        - Optional. Time of the first discovery.
     last_discovered                         - Optional. Time of the last discovery.
     netbios                                 - Optional. Discovered NetBIOS name (regular expression).
     network_component_description           - Optional. Discovered network component description (regular
expression).
     network_component_ip                    - Optional. Discovered network component IP address (regular
expression).
     network_component_name                  - Optional. Discovered network component name (regular
```

```
expression).
  network_component_port_description    - Optional. Discovered network component port description
(regular expression).
  network_component_port_name           - Optional. Discovered network component port name (regular
expression).
  network_component_port_number         - Optional. Discovered network component port number.
  network_component_type                - Optional. Discovered network component type (regular
expression).
  os                                    - Optional. Discovered OS (regular expression).
  port_duplex                           - Optional. Discovered port duplex settings.
  port_link_status                      - Optional. Discovered port link status.
  port_speed                            - Optional. Discovered port speed settings.
  port_status                           - Optional. Discovered port status settings.
  port_vlan_description                 - Optional. Discovered port VLAN description (regular
expression).
  port_vlan_name                        - Optional. Discovered port VLAN name (regular expression).
  port_vlan_number                      - Optional. Discovered port VLAN number.
  v_cluster                             - Optional. Discovered VMware cluster name (regular
expression).
  v_datacenter                          - Optional. Discovered VMware datacenter name (regular
expression).
  v_host                                - Optional. Discovered VMware server name (regular
expression).
  v_name                                - Optional. Discovered VMware host or virtual machine name
(regular expression).
  v_netadapter                          - Optional. Discovered VMware physical network adapter name
(regular expression).
  v_switch                              - Optional. Discovered VMware virtual switch name (regular
expression).
  v_type                                - Optional. Discovered VMware entity type (possible values:
"VirtualMachine", "HostSystem", "VirtualCenter").
```

Examples

```
# Search DHCP Host Address object through the session
my @retrieved_objs = $session->search(
    object       => "Infoblox::DHCP::HostAddr",
    mac          => "11:11:11:11:11.*",
);

# search HostAddr by v_datacenter:
my @retrieved_objs = $session->search(
   object                => 'Infoblox::DHCP::HostAddr',
   v_datacenter => 'test.*');
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DHCP Host Address object.

bootfile( )

Use this method to set or retrieve the bootfile value of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that when bootfile is set to a defined value and override_bootfile is set to "false", the last operation takes precedence. Thus the sequence $object->bootfile("boot_file"); $object->override_bootfile("false"); will set override_bootfile to "false", and the sequence $object->override_bootfile("false"); $object->bootfile("boot_file"); will set override_bootfile to "true".

Parameter

The name of the file that the client must download. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootfile
my $bootfile = $host_addr->bootfile();
#Modify bootfile
$host_addr->bootfile("boot_file");
```

bootserver( )

Use this method to set or retrieve the bootserver of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that when bootserver is set to a defined value and override_bootserver is set to "false", the last operation takes precedence. Thus

the sequence $object->bootserver("bootserver2.com"); $object->override_bootserver("false"); will set override_bootserver to "false", and the sequence $object->override_bootserver("false"); $object->bootserver("bootserver2.com"); will set override_bootserver to "true".

Parameter

The boot server IP address or FQDN (Fully Qualified Domain Name). The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootserver
my $bootserver = $host_addr->bootserver();
#Modify bootserver
$host_addr->bootserver("bootserver2.com");
#Un-override bootserver
$host_addr->bootserver(undef);
```

configure_for_dhcp( )

Use this method to set or retrieve the configure_for_dhcp flag of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the configure_for_dhcp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get configure_for_dhcp
my $configure_for_dhcp = $host_addr->configure_for_dhcp();
#Modify configure_for_dhcp
$host_addr->configure_for_dhcp("true");
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that when deny_bootp is set to a defined value and override_deny_bootp is set to "false", the last operation takes precedence. Thus the sequence $object->deny_bootp("true"); $object->override_deny_bootp("false"); will set override_deny_bootp to "false", and the sequence $object->override_deny_bootp("false"); $object->deny_bootp("true"); will result in override_deny_bootp="true".

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $host_addr->deny_bootp();
#Modify deny_bootp
$host_addr->deny_bootp("true");
```

discovered_data( )

Use this method to retrieve the discovered data of a DHCP Host Address object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Data object.

Example

```
#Get discovered_data value
my $discovered_data = $object->discovered_data();
```

discovered_mac( )

Use this method to retrieve the discovered MAC address of a DHCP Host Address object.

Parameter

none

Returns

The method returns the discovered MAC address.

Example

```
#Get discovered_mac
my $discovered_mac = $host_addr->discovered_mac();
```

discovered_name( )

Use this method to retrieve the discovered name of a DHCP Host Address object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
my $discovered_name = $host_addr->discovered_name();
```

discoverer( )

Use this method to retrieve the discoverer of a DHCP Host Address object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $host_addr->discoverer();
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $host_addr->discover_now_status();
```

enable_pxe_lease_time( )

Use this method to set or retrieve the enable_pxe_lease_time flag of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_pxe_lease_time flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_pxe_lease_time
my $enable_pxe_lease_time = $host_addr->enable_pxe_lease_time();
#Modify enable_pxe_lease_time
$host_addr->enable_pxe_lease_time("true");
```

first_discovered( )

Use this method to retrieve the date and time that the DHCP Host Address object was first discovered.

Parameter

none

Returns

The method returns the date and time that the DHCP Host Address object was first discovered.

Example

```
#Get first_discovered
my $first_discovered = $host_addr->first_discovered();
```

host( )

Use this method to retrieve the name of the Host record this address belongs to.

Parameter

none

Returns

The method returns the host value.

Example

```
#Get host
my $host = $host_addr->host();
```

ignore_client_requested_options( )

Use this method to set or retrieve the ignore_client_requested_option flag of a DHCP Host address object. If this flag is set to false, all the defined DHCP options are returned to the client.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that when ignore_client_requested_options is set to a defined value and override_ignore_client_requested_options is set to "false", the last operation takes precedence. Thus the sequence $object->ignore_client_requested_options("true"); $object->override_ignore_client_requested_options("false"); will set override_ignore_client_requested_options to "false", and the sequence $object->override_ignore_client_requested_options("false"); $object->ignore_client_requested_options("true"); will set override_ignore_client_requested_options to "true".

Parameter

Specify "true" to set the ignore_client_requested_option flag or "false" to deactivate/unset it. The default value is false, which

indicates that this attribute inherits the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_client_requested_option
my $ignore_client_requested_option = $host_addr->ignore_client_requested_options();
# Un-override ignore_client_requested_option
$host_addr->ignore_client_requested_options(undef);
# Modify ignore_client_requested_option
$host_addr->ignore_client_requested_options("true");
```

ipv4addr( )

Use this method to set or retrieve the ipv4addr value of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $host_addr->ipv4addr();
#Modify ipv4addr
$host_addr->ipv4addr("10.0.0.5");
```

is_invalid_mac( )

Use this method to retrieve the flag used to indicate whether an invalid MAC address is used. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get is_invalid_mac value
my $is_invalid_mac = $host_addr->is_invalid_mac();
```

last_discovered( )

Use this method to retrieve the time this object was last seen by a discovery job.

The default value for this field is empty.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get last_discovered
my $last_discovered = $host_addr->last_discovered();
```

last_queried( )

Use this method to retrieve the time when the associated record was last queried. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_queried
my $last_queried = $host_addr->last_queried();
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Host Address.

Filters are used to screen address assignments for the DHCP Host Address if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $host_addr->logic_filters();
#Modify logic_filters
$host_addr->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an Infoblox::DHCP::Filter::MAC,
Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

mac( )

Use this method to set or retrieve the MAC address value of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

MAC Address of the DHCP Host address object. The format for MAC addresses and vendor prefixes are hexadecimal strings separated by colons or dashes. The following formats are acceptable: 11:11:11:11:11:11 and 11-11-11-11-11-11.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mac
my $mac = $host_addr->mac();
#Modify mac
$host_addr->mac("11::11::11::11::11::12");
```

match_client( )

Use this method to set or retrieve the match_client value of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

```
    match_client "MAC": The fixed IP address is leased to the matching MAC address.

    match_client "CLIENT_IDENTIFIER": The fixed IP address is leased to the matching DHCP client
identifier

    match_client "RESERVED": The fixed IP address is reserved for later use with a MAC address that
only has zeros.

    match_client "CIRCUIT_ID": The fixed IP address is leased to the DHCP client with a matching
circuit ID. Note that
                  the "agent_circuit_id" field must be set in this case.

    match_client "REMOTE_ID": The fixed IP address is leased to the DHCP client with a matching
remote ID. Note that
                  the "agent_remote_id" field must be set in this case.
```

Returns

```
    If you specified a parameter, the method returns true when the modification succeeds, and returns
false when the operation fails.

    If you did not specify a parameter, the method returns the attribute value.
```

Example

```
#Get match_client
my $match_client = $host_addr->match_client();
#Modify match_client
$host_addr->match_client("CLIENT_IDENTIFIER");
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data value
my $value = $object->ms_ad_user_data();
```

netbios( )

Use this method to retrieve the name in the NetBIOS reply that responded to a NetBIOS query.

Returns

The method returns the attribute value.

Example

```
#Get netbios
my $netbios = $host_addr->netbios();
```

network( )

Use this method to retrieve the network value of a DHCP Host Address object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get network
my $network = $host_addr->network();
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $host_addr->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the IP address of the network device.

Example

```
#Get network_component_ip
my $network_component_ip = $host_addr->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the network device name.

Example

```
#Get network_component_name
my $network_component_name = $host_addr->network_component_name();
```

network_component_port_description( )

Use this method to retrieve the description of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the description of the port on the network device.

Example

```
#Get network_component_port_description
my $network_component_port_description = $host_addr->network_component_port_description();
```

network_component_port_name( )

Use this method to retrieve the name of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the name of the port on the network device.

Example

```
#Get network_component_port_name
my $network_component_port_name = $host_addr->network_component_port_name();
```

network_component_port_number( )

Use this method to retrieve the number of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the network device port number.

Example

```
#Get network_component_port_number
my $network_component_port_number = $host_addr->network_component_port_number();
```

network_component_type( )

Use this method to retrieve the type of the network device that is connected to DHCP Host Address object.

Parameter

none

Returns

The method returns the network device type.

Example

```
#Get network_component_type
my $network_component_type = $host_addr->network_component_type();
```

nextserver( )

Use this method to set or retrieve the nextserver value of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that when nextserver is set to a defined value and override_nextserver is set to "false", the last operation takes precedence. Thus the sequence $object->nextserver("3.3.3.4"); $object->override_nextserver("false"); will set override_nextserver to "false", and the sequence $object->override_nextserver("false"); $object->nextserver("3.3.3.4"); will set override_nextserver to "true".

Parameter

The next server IP address or FQDN (Fully Qualified Domain Name). The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nextserver
my $nextserver = $host_addr->nextserver();
#Modify nextserver
$host_addr->nextserver("3.3.3.4");
#Un-override nextserver
$host_addr->nextserver(undef);
```

options( )

Use this method to set or retrieve the options of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

See Infoblox::DHCP::Option for parameters and methods available for this object.

Note that when options is set to a defined value and override_options is set to "false", the last operation takes precedence. Thus the sequence $object->options([$o1,$o2]); $object->override_options("false"); will set override_options to "false", and the sequence $object->override_options("false"); $object->options([$o1,$o2]); will set override_options to "true".

Parameter

Options describe network configuration settings and various services available on the network. These options occur as variable-length fields at the end of DHCP messages.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $host_addr->options();
#Modify options
$host_addr->options([$option1, $option2]);
```

os( )

Use this method to retrieve the operating system associated with this host address.

Returns

The method returns the attribute value.

Example

```
#Get os
my $os = $host_addr->os();
```

override_bootfile( )

The override_bootfile attribute controls whether the bootfile value in the member is used, instead of the grid default.

The override_bootfile attribute can be specified explicitly. It is also set implicitly when bootfile is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_bootfile flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_bootfile
my $override = $host_addr->override_bootfile();
#Modify the override
$host_addr->override_bootfile("true");
```

override_bootserver( )

The override_bootserver attribute controls whether the bootserver value in the member is used, instead of the grid default.

The override_bootserver attribute can be specified explicitly. It is also set implicitly when bootserver is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_bootserver flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_bootserver
my $override = $host_addr->override_bootserver();
#Modify the override
$host_addr->override_bootserver("true");
```

override_deny_bootp( )

The override_deny_bootp attribute controls whether the deny_bootp value in the member is used, instead of the grid default.

The override_deny_bootp attribute can be specified explicitly. It is also set implicitly when deny_bootp is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_deny_bootp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_deny_bootp
my $override = $host_addr->override_deny_bootp();
#Modify the override
$host_addr->override_deny_bootp("true");
```

override_ignore_client_requested_option( )

The override_ignore_client_requested_option attribute controls whether the ignore_client_requested_option value in the member is used, instead of the grid default.

The override_ignore_client_requested_option attribute can be specified explicitly. It is also set implicitly when ignore_client_requested_option is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_ignore_client_requested_option flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ignore_client_requested_option
my $override = $host_addr->override_ignore_client_requested_option();
#Modify the override
$host_addr->override_ignore_client_requested_option("true");
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value of the DHCP Host Address is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$host_addr->override_logic_filters( );
#Modifying override_logic_filters
$host_addr->override_logic_filters("true");
```

override_nextserver( )

The override_nextserver attribute controls whether the nextserver value in the member is used, instead of the grid default.

The override_nextserver attribute can be specified explicitly. It is also set implicitly when nextserver is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_nextserver flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_nextserver
my $override = $host_addr->override_nextserver();
#Modify the override
$host_addr->override_nextserver("true");
```

override_options( )

The override_options attribute controls whether the options value in the member is used, instead of the upper-level default.

The override_options attribute can be specified explicitly. It is also set implicitly when options is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_options flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_options
my $override = $host_addr->override_options();
#Modify the override
$host_addr->override_options("true");
```

override_pxe_lease_time( )

The override_pxe_lease_time attribute controls whether the pxe_lease_time value in the member is used, instead of the grid default.

The override_pxe_lease_time attribute can be specified explicitly. It is also set implicitly when pxe_lease_time is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the override_pxe_lease_time flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_pxe_lease_time
my $override = $host_addr->override_pxe_lease_time();
#Modify the override
$host_addr->override_pxe_lease_time("true");
```

port_duplex( )

Use this method to retrieve the duplex setting of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the port duplex setting. The returned value, if any, is one of the following:

```
Full
Half
```

Example

```
#Get port_duplex
my $port_duplex = $host_addr->port_duplex();
```

port_link_status( )

Use this method to retrieve the link status of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the network device port link status. The returned value, if any, is one of the following:

```
Connected
Not Connected
Unknown
```

Example

```
#Get port_link_status
my $port_link_status = $host_addr->port_link_status();
```

port_speed( )

Use this method to retrieve the speed of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the network device port speed. The returned value, if any, is one of the following:

```
10M
100M
1G
10G
100G
Unknown
```

Example

```
#Get port_speed
my $port_speed = $host_addr->port_speed();
```

port_status( )

Use this method to retrieve the status of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the network device port status. The returned value, if any, is one of the following:

```
Up
Down
Unknown
```

Example

```
#Get port_status
my $port_status = $host_addr->port_status();
```

port_vlan_description( )

Use this method to retrieve the VLAN description of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the VLAN description of the network device port.

Example

```
#Get port_vlan_description
my $port_vlan_description = $host_addr->port_vlan_description();
```

port_vlan_name( )

Use this method to retrieve the VLAN name of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the network device port VLAN name.

Example

```
#Get port_vlan_name
my $port_vlan_name = $host_addr->port_vlan_name();
```

port_vlan_number( )

Use this method to retrieve the VLAN number of the network device port that is connected to the DHCP Host Address object.

Parameter

none

Returns

The method returns the port VLAN number.

Example

```
#Get port_vlan_number
my $port_vlan_number = $host_addr->port_vlan_number();
```

pxe_lease_time( )

Use this method to set or retrieve the pxe_lease_time value of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Note that when pxe_lease_time is set to a defined value and override_pxe_lease_time is set to "false", the last operation takes precedence. Thus the sequence $object->pxe_lease_time("369"); $object->override_pxe_lease_time("false"); will set override_pxe_lease_time to "false", and the sequence $object->override_pxe_lease_time("false"); $object->pxe_lease_time("369"); will set override_pxe_lease_time to "true".

Parameter

Enter appropriate values in the Days, Hours, Mins and Secs fields. User can specify the duration of time it takes a host to connect to a boot server, such as a TFTP server, and download the file it needs to boot.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get pxe_lease_time
my $pxe_lease_time = $host_addr->pxe_lease_time();
#Modify pxe_lease_time
$host_addr->pxe_lease_time("369");
```

reserved_interface( )

Use this method to set or retrieve the reserved discovery interface.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get reserved_interface
my $reserved_interface = $host_addr->reserved_interface();
#Modify reserved_interface
$host_addr->reserved_interface($interface);
```

v_cluster( )

Use this method to retrieve the name of the VMware cluster associated with the DHCP Host Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware cluster name. The default value is an empty string.

Example

```
#Get v_cluster
my $v_cluster = $host_addr->v_cluster();
```

v_datacenter( )

Use this method to retrieve the name of the VMware datacenter associated with the DHCP Host Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware datacenter name. The default value is an empty string.

Example

```
#Get v_datacenter
my $v_datacenter = $host_addr->v_datacenter();
```

v_host( )

Use this method to retrieve the name of the VMware host associated with the DHCP Host Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware host name. The default value is an empty string.

Example

```
#Get v_host
my $v_host = $host_addr->v_host();
```

v_name( )

Use this method to retrieve the name of the VMware entity associated with the DHCP Host Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware entity name. The default value is an empty string.

Example

```
#Get v_name
my $v_name = $host_addr->v_name();
```

v_netadapter( )

Use this method to retrieve the name of the physical network adapter through which the VMware entity is connected to the appliance. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the network adapter name. The default value is an empty string.

Example

```
#Get v_netadapter
my $v_netadapter = $host_addr->v_netadapter();
```

v_switch( )

Use this method to retrieve the name of the virtual switch through which the VMware entity is connected to the appliance. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the virtual switch name. The default value is an empty string.

Example

```
#Get v_switch
my $v_switch = $host_addr->v_switch();
```

v_type( )

Use this method to retrieve the type of VMware entity associated with the DHCP Host Address object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware entity type. The default value is an empty string. The returned value, if any, can be one of the following:

```
VirtualMachine
```

```
HostSystem
VirtualCenter
```

Example

```
#Get v_type
my $v_type = $host_addr->v_type();
```

use_for_ea_inheritance( )

Use this method to set or retrieve the flag that indicates if this host address is used for inheritable extensible attributes.

Parameter

Specify "true" to enable the flag or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get use_for_ea_inheritance
my $use_for_ea_inheritance = $host_addr->use_for_ea_inheritance();
#Modify use_for_ea_inheritance
$host_addr->use_for_ea_inheritance("true");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as search and modify. This sample also includes error handling for the operations.

#Preparation prior to a DHCP IPv4 Host Address object insertion

```
#PROGRAM STARTS: Include all the modules that will be used, note the hostaddress option
use strict;
use Infoblox qw (:hostaddress);

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
              master   => "192.168.1.2", #appliance host ip
              username => "admin",       #appliance user login
              password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
              Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create an IPv4 network object
my $network = Infoblox::DHCP::Network->new(
                                          "network" => "10.0.0.0/8",
                                         );
unless($network) {
     die("Construct IPv4 Network object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "IPv4 Network object created successfully\n";

$session->add($network)
    or die("Add network failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Network added successfully\n";

#Create a zone object
my $zone = Infoblox::DNS::Zone->new(
                                    name => "test.com",
                                   );
unless($zone) {
     die("Construct Zone object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
```

```
print "Zone object created successfully\n";

$session->add($zone)
    or die("Add zone failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Zone added successfully\n";

my $option1 = Infoblox::DHCP::Option->new(
                                          name  => "routers",
                                          value => "10.0.0.100,10.0.0.200"
                                         );

unless($option1) {
    die("Construct option1 object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "option1 object created successfully\n";

my $option2 = Infoblox::DHCP::Option->new(
                                          name  => "nameservers",
                                          value => "1.1.1.1,2.2.2.2,3.3.3.3"
                                         );
unless($option2) {
    die("Construct option2 object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());

NAME

Infoblox::DHCP::IPv6FixedAddr - DHCP IPv6 Fixed Address object.

DESCRIPTION

An IPv6 Fixed Address is a specific IP address that a DHCP server always assigns when a lease request comes from a particular MAC address of the client. This is an IPv6 representation of a fixed address.

CONSTRUCTOR

```
 my $ipv6fa = Infoblox::DHCP::IPv6FixedAddr -> new(
       duid                          => $string,                    # Required
       address_type                  => "ADDRESS" | "PREFIX" | "BOTH", # Optional / Default is "ADDRESS"
       comment                       => $string,                    # Optional / Default is empty
       configure_for_dhcp            => "true" | "false",           # Optional / Default is "false"
                                                                    # When both the IP address and DUID
are present, the default value is "true"
                                                                    # Applicable only when adding this
fixed address to a host
       disable                       => "true" | "false",           # Optional / Default is "false"
       domain_name                   => $string,                    # Optional / Default is undefined
       domain_name_servers           => "$ipv6addr1,$ipv6addr2,...", # Optional / Default is undefined
       extattrs                      => { $string => $extattr, ... },#Optional / Default is undefined
       extensible_attributes         => { $string => $string | $num, $string => [ $string | $num, ... ],
... } #Optional / Default is undefined
       ipv6addr                      => $ipv6addr,                  # Optional / one of ipv6addr or
ipv6prefix is required
       ipv6prefix                    => $ipv6addr,                  # Optional / one of ipv6addr or
ipv6prefix is required
       ipv6prefix_bits               => $ipv6addr,                  # Optional / Required if ipv6prefix
is specified
       match_client                  => $string,                    # Optional / Default is "DUID"
                                                                    # Possible values are:
                                                                    #   "DUID", "RESERVED",
       name                          => $string,                    # Optional / Default is undefined
       network                       => $ipv6network,               # Optional / Default is undefined
       network_view                  => $NetworkView,               # Optional / Default is "default"
network view
       options                       => [$option1, $option2, ...]   # Optional / Default is empty
       override_domain_name          => "true" | "false",           # Optional / Default value is
"false"
       override_domain_name_servers  => "true" | "false",           # Optional / Default value is
"false"
       override_options              => "true" | "false",           # Optional / Default value is
"false"
       override_preferred_lifetime   => "true" | "false",           # Optional / Default value is
"false"
       override_valid_lifetime       => "true" | "false",           # Optional / Default value is
"false"
       preferred_lifetime            => $num,                       # Optional / Default is "27000"
       template                      => $string,                    # Optional / Default is undefined
       valid_lifetime                => $num,                       # Optional / Default is 43200
       cli_credentials               => [$cli1, ...],               # Optional
       override_cli_credentials      => "true" | "false",           # Optional / Default is "false"
       reserved_interface            => $interface,                 # Optional
       device_type                   => $string,                    # Optional
       device_vendor                 => $string,                    # Optional
       device_location               => $string,                    # Optional
       device_description            => $string,                    # Optional
       allow_telnet                  => "true" | "false",           # Optional / Default is "false"
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DHCP IPv6 Fixed Address object.

Infoblox::Session->add( )

Use this method to add a DHCP IPv6 Fixed Address object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct a DHCP IPv6 Fixed Address object
my $ipv6fa = Infoblox::DHCP::IPv6FixedAddr->new(
       duid                    => "0001",
       comment                 => "add ipv6 fixed address using uid",
       disable                 => "false",
       match_client            => "DUID",
       network                 => "2001::/24",
       network_view            => $nview,
       options                 => [ $option1,  $option2, $option3,  $option4, $option5, $option6 ],
);

#Submit for addition
my $response = $session->add($ipv6fa)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 Fixed Address object:

  comment                                 - Optional. User-specified comment for the fixed address.
  duid                                    - Optional. DUID of the fixed address.
  ipv6addr                                - Optional. IPv6 address of the fixed address.
  network                                 - Optional. Network address of the fixed address.
  network_view                            - Optional. Network view in which the fixed address is
located. By default, all network views are searched.
  extattrs                                - Optional. A hash reference containing extensible
attributes.
  extensible_attributes                   - Optional. A hash reference containing extensible
attributes.

  discovered_duid                         - Optional. Discovered DHCPv6 UID.
  discovered_name                         - Optional. Discovered name.
  discoverer                              - Optional. Discoverer name.
  first_discovered                        - Optional. Time of the first discovery.
  last_discovered                         - Optional. Time of the last discovery.
  netbios                                 - Optional. Discovered NetBIOS name.
  network_component_description           - Optional. Discovered network component description.
  network_component_ip                    - Optional. Discovered network component IP address.
  network_component_name                  - Optional. Discovered network component name.
  network_component_port_description      - Optional. Discovered network component port description.
  network_component_port_name             - Optional. Discovered network component port name.
  network_component_port_number           - Optional. Discovered network component port number.
  network_component_type                  - Optional. Discovered network component type.
  os                                      - Optional. Discovered OS.
  port_duplex                             - Optional. Discovered port duplex settings.
  port_link_status                        - Optional. Discovered port link status.
  port_speed                              - Optional. Discovered port speed settings.
  port_status                             - Optional. Discovered port status settings.
  port_vlan_description                   - Optional. Discovered port VLAN description.
  port_vlan_name                          - Optional. Discovered port VLAN name.
  port_vlan_number                        - Optional. Discovered port VLAN number.
```

Examples

```
#Get DHCP IPv6 Fixed Address object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6FixedAddr",
    duid   => "0001",
);
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::IPv6FixedAddr",
    ipv6addr     => "2001::1",
    network_view => "default",
);

my @retrieved_objs = $session->get(
   object                => "Infoblox::DHCP::IPv6FixedAddr",
   extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP IPv6 Fixed Address object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the preferred_lifetime
$ipv6fa->preferred_lifetime("1234567");
#Submit modification
my $response = $session->modify( $ipv6fa );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP IPv6 Fixed Address object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP IPv6 Fixed Address object, and then submit this object for removal.

Example

```
#Get DHCP IPv6 Fixed Address object through the session
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::IPv6FixedAddr",
    duid         => "0001",
    network_view => "default"
);
#Find the desired object from the retrieved list.
my $desired_ipv6fa = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_ipv6fa );
```

Infoblox::Session->search( )

Use this method to search for DHCP IPv6 Fixed Address object and matching Host object with MAC address in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
 Apply the following attributes to search for a specific DHCP IPv6 Fixed Address object:

  comment                                 - Optional. User-specified comment for the fixed address.
  duid                                    - Optional. DUID of the fixed address.
  ipv6addr                                - Optional. IPv6 address of the fixed address.
  network                                 - Optional. Network address of the fixed address.
  network_view                            - Optional. Network view in which the fixed address is
located. By default, all network views are searched.
  discovered_duid                         - Optional. Discovered DHCPv6 UID (exact search only).
  discovered_name                         - Optional. Discovered name(regex).
  discoverer                              - Optional. Discoverer name(regex).
  first_discovered                        - Optional. Time of the first discovery (in ISO format, exact
search only).
  last_discovered                         - Optional. Time of the last discovery (in ISO format, exact
search only).
  netbios                                 - Optional. Discovered NetBIOS name(regex).
  network_component_description           - Optional. Discovered network component description(regex).
  network_component_ip                    - Optional. Discovered network component IP address(regex).
  network_component_name                  - Optional. Discovered network component name(regex).
  network_component_port_description      - Optional. Discovered network component port
description(regex).
  network_component_port_name             - Optional. Discovered network component port name(regex).
  network_component_port_number           - Optional. Discovered network component port number (exact
search only).
  network_component_type                  - Optional. Discovered network component type(regex).
  os                                      - Optional. Discovered OS (regex).
  port_duplex                             - Optional. Discovered port duplex settings (exact search
only).
  port_link_status                        - Optional. Discovered port link status (exact search only).
  port_speed                              - Optional. Discovered port speed settings (exact search
only).
  port_status                             - Optional. Discovered port status settings (exact search
only).
  port_vlan_description                   - Optional. Discovered port VLAN description(regex).
  port_vlan_name                          - Optional. Discovered port VLAN name(regex).
  port_vlan_number                        - Optional. Discovered port VLAN number(exact search only).

  extattrs                                - Optional. A hash reference containing extensible
attributes.
  extensible_attributes                   - Optional. A hash reference containing extensible
attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
 # Search for all DHCP IPv6 Fixed Address objects that are specified in the network "2001::/24" in
the "default" network view.
```

```
my @retrieved_objs = $session->search(
    object       => "Infoblox::DHCP::IPv6FixedAddr",
    duid         => "0001",
    network      => "2001::/24",
    network_view => "default"
);

# Search for all DHCP IPv6 Fixed Address objects with "Santa Clara" for the "Site" extensible
attribute
my @retrieved_objs = $session->search(
    object                => "Infoblox::DHCP::IPv6FixedAddr",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DHCP IPv6 Fixed Address object.

address_type( )

Use this method to set or retrieve the address type of a DHCP IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "ADDRESS", "PREFIX", or "BOTH". When the address type is "ADDRESS", a value for the 'ipv6addr' member is required. When the address type is "PREFIX", values for 'ipv6prefix' and 'ipv6prefix_bits' are required. When the address type is "BOTH", values for 'ipv6addr', 'ipv6prefix', and 'ipv6prefix_bits' are all required.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address_type
my $address_type = $ipv6fa->address_type();
#Modify address_type
$ipv6fa->address_type("PREFIX");
```

allow_telnet( )

Use this method to set or retrieve the flag that enables copying SSH credential to TELNET.

Parameter

Specify 'true' to copy SSH credential to TELNET or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $ipv6fa->allow_telnet();
# Modify attribute value
$ipv6fa->allow_telnet('true');
```

comment( )

Use this method to set or retrieve the descriptive comment of a DHCP IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $ipv6fa->comment();
#Modify comment
$ipv6fa->comment("Modified DHCP IPv6 Fixed Address object comment");
```

configure_for_dhcp( )

Use this method to set or retrieve the configure_for_dhcp flag of a DHCP IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the configure_for_dhcp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get configure_for_dhcp
my $configure_for_dhcp = $ipv6fa->configure_for_dhcp();
#Modify configure_for_dhcp
$ipv6fa->configure_for_dhcp("true");
```

cli_credentials( )

Use this method to set or retrieve the discovery CLI credentials.

Setting this method to a defined value implicitly sets the override_cli_credentials method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_cli_credentials attribute to "false".

Note that when cli_credentials is set to a defined value and override_cli_credentials is set to "false", the last operation takes precedence. Thus the sequence $ipv6fa->cli_credentials([$cli]); $ipv6fa->override_cli_credentials("false"); will set override_cli_credentials to "false", and the sequence $ipv6fa->override_cli_credentials("false"); $ipv6fa->cli_credentials([$cli]); will result in override_cli_credentials="true".

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::CLICredential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get cli_credentials
my $cli_credentials = $ipv6fa->cli_credentials();
#Modify cli_credentials
$ipv6fa->cli_credentials([$cli1, $cli2]);
```

cloud_info( )

Use this method to retrieve cloud API related information for the Infoblox::DHCP::IPv6FixedAddr object.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $object->cloud_info();
```

device_description( )

Use this method to set or retrieve the description of the discovery device.

Parameter

The device description in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_description
my $device_description = $ipv6fa->device_description();
#Modify device_description
$ipv6fa->device_description('example');
```

device_location( )

Use this method to set or retrieve the location of the discovery device.

Parameter

The device location in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_location
my $device_location = $ipv6fa->device_location();
#Modify device_location
$ipv6fa->device_location('example');
```

device_type( )

Use this method to set or retrieve the type of the discovery device.

Parameter

The device type in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_type
my $device_type = $ipv6fa->device_type();
#Modify device_type
$ipv6fa->device_type('example');
```

device_vendor( )

Use this method to set or retrieve the vendor name of the discovery device.

Parameter

The device vendor name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_vendor
```

```
my $device_vendor = $ipv6fa->device_vendor();
#Modify device_vendor
$ipv6fa->device_vendor('example');
```

disable( )

Use this method to set or retrieve the disable flag of a DHCP IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $ipv6fa->disable();
#Modify disable
$ipv6fa->disable("true");
```

=head2 discovered_data( )

Use this method to retrieve the discovered data of a DHCP IPv6 Fixed Address object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Data object.

Example

```
#Get discovered_data value
my $discovered_data = $object->discovered_data();
```

discovered_duid( )

Use this method to retrieve the discovered DHCPv6 UID (DUID) of a DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_duid
my $discovered_duid = $ipv6fa->discovered_duid();
```

discovered_name( )

Use this method to retrieve the discovered name of a DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
```

```
my $discovered_name = $ipv6fa->discovered_name();
```

discoverer( )

Use this method to retrieve the discoverer of a DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $ipv6fa->discoverer();
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $ipv6fa->discover_now_status();
```

domain_name( )

Use this method to set or retrieve the domain_name value of a DHCP IPv6 fixed address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_domain_name attribute to "false".

Note that when domain_name is set to a defined value and override_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name("testdomain"); $object->override_domain_name("false"); will set override_domain_name to "false", and the sequence $object->override_domain_name("false"); $object->domain_name("testdomain"); will result in override_domain_name="true".

Parameter

The client's domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name
my $domain_name = $ipv6fa->domain_name();
#Modify domain_name
$ipv6fa->domain_name("test_domain.com");
```

domain_name_servers( )

Use this method to set or retrieve the domain_name_servers value of a DHCP IPv6 fixed address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_domain_name_servers attribute to "false".

Note that when domain_name_servers is set to a defined value and override_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name_servers("2001::1,2001::2"); $object->override_domain_name_servers("false"); will set override_domain_name_servers to "false", and the sequence $object->override_domain_name_servers("false"); $object->domain_name_servers("2001::1,2001::2"); will result in override_domain_name_servers="true".

Parameter

The comma-separated list of domain name server addresses in IPv6 address format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name_servers
my $domain_name_servers = $ipv6fa->domain_name_servers();
#Modify domain_name_servers
$ipv6fa->domain_name_servers("2001::1,2001::2");
```

duid( )

Use this method to set or retrieve the DHCPv6 Unique Identifier (DUID) of the IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The DUID of the matching client in hexadecimal format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get duid
my $duid = $ipv6fa->duid();
#Modify duid
$ipv6fa->duid("1c2edfaa");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with an IPv6 Fixed Address object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $ipv6fa->extattrs();
#Modify extattrs
$ipv6fa->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with an IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $ipv6fa->extensible_attributes();
#Modify extensible attributes
$ipv6fa->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

first_discovered( )

Use this method to retrieve the date and time that the DHCP IPv6 Fixed Address object was first discovered.

Parameter

none

Returns

The method returns the date and time that the DHCP IPv6 Fixed Address object was first discovered.

Example

```
#Get first_discovered
my $first_discovered = $ipv6fa->first_discovered();
```

ipv6addr( )

Use this method to set or retrieve the the IPv6 address of the IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1), and dotted-quad notation can be used to express IPv4-mapped IPv6 addresses (example: ::ffff:192.0.2.128).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6addr
my ipv6addr = $ipv6fa->ipv6addr();
#Modify ipv6addr
$ipv6fa->ipv6addr("aaaa:1111:bbbb:2222:cccc:3333:dddd:5555");
```

ipv6prefix( )

Use this method to set or retrieve the IPv6 prefix of a DHCP IPv6 Fixed Address object. The prefix must belong to the list of global prefixes defined in the Infoblox::Grid::DHCP object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IPv6 prefix from the list of global IPv6 prefixes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.
ls.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6prefix
my $ipv6prefix = $ipv6fa->ipv6prefix();
#Modify ipv6prefix
```

```
$ipv6fa->ipv6prefix("2001::");
```

ipv6prefix_bits( )

Use this method to set or retrieve the prefix bits for the DHCP IPv6 Fixed Address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An unsigned integer between 2 and 128.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6prefix_bits
my $ipv6prefix_bits = $ipv6fa->ipv6prefix_bits();
#Modify ipv6prefix_bits
$ipv6fa->ipv6prefix_bits(32);
```

last_discovered( )

Use this method to retrieve the time this object was last seen by a discovery job.

The default value for this field is empty.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get last_discovered
my $last_discovered = $ipv6fa->last_discovered();
```

match_client( )

Use this method to set or retrieve the match_client value of a DHCP Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

```
match_client "DUID": The fixed IP address is leased to the matching DUID.
```

Returns

```
If you specified a parameter, the method returns true when the modification succeeds, and returns
false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.
```

Example

```
#Get match_client
my $match_client = $ipv6fa->match_client();
#Modify match_client
$ipv6fa->match_client("DUID");
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $ipv6fa->ms_ad_user_data();
```

name( )

Use this method to set or retrieve the name of a DHCP IPv6 Fixed Address object. The same name can be used for multiple fixed addresses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify a name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the name
my $name = $ipv6fa->name();
#Modify the name
$ipv6fa->name("pop-server");
```

netbios( )

Use this method to retrieve the name in the NetBIOS reply that responded to a NetBIOS query.

Returns

The method returns the attribute value.

Example

```
#Get NetBIOS
my $netbios = $ipv6fa->netbios();
```

network( )

Use this method to retrieve the network value of a DHCP IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the address and netmask of the network in CIDR format (example: 2001::/64).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network
my $network = $ipv6addr->network();
#Modify network
$ipv6fa->network("2001::/24");
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $ipv6fa->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the IP address of the network device.

Example

```
#Get network_component_ip
my $network_component_ip = $ipv6fa->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the network device name.

Example

```
#Get network_component_name
my $network_component_name = $ipv6fa->network_component_name();
```

network_component_port_description( )

Use this method to retrieve the description of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the description of the port on the network device.

Example

```
#Get network_component_port_description
my $network_component_port_description = $ipv6fa->network_component_port_description();
```

network_component_port_name( )

Use this method to retrieve the name of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the name of the port on the network device.

Example

```
#Get network_component_port_name
my $network_component_port_name = $ipv6fa->network_component_port_name();
```

network_component_port_number( )

Use this method to retrieve the number of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the network device port number.

Example

```
#Get network_component_port_number
my $network_component_port_number = $ipv6fa->network_component_port_number();
```

network_component_type( )

Use this method to retrieve the type of the network device that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the network device type.

Example

```
#Get network_component_type
my $network_component_type = $ipv6fa->network_component_type();
```

network_view( )

Use this method to set or retrieve the network view of the DHCP fixed address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the fixed address is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $ipv6fa->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$ipv6fa->network_view($nview);
```

options( )

Use this method to set or retrieve the options of a DHCP IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_options method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_options attribute to "false".

Note that when the options method is set to a defined value and override_options is set to "false", the last operation takes precedence. Thus the sequence $object->options([$opt]); $object->override_options("false"); will set override_options to "false", and the sequence $object->override_options("false"); $object->options([$opt]); will result in override_options="true".

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $ipv6fa->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name   => "dhcp6.rapid-commit",
    value  => "true"
);
$ipv6fa->options([$option1);
```

os( )

Use this method to retrieve the operating system associated with this fixed address.

Returns

The method returns the attribute value.

Example

```
#Get OS
my $os = $ipv6fa->os();
```

override_domain_name( )

The override_domain_name attribute controls whether the domain_name value in the DHCP IPv6 fixed address is used, instead of the upper-level default.

The override_domain_name attribute can be specified explicitly. It is also set implicitly when domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for domain_name. Set the parameter to "false" to inherit the upper-level setting for domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_domain_name
my $override_domain_name=$ipv6fa->override_domain_name( );
#Modify override_domain_name
$ipv6fa->override_domain_name("true");
```

override_domain_name_servers( )

The override_domain_name_servers attribute controls whether the domain_name_servers value in the DHCP IPv6 fixed address is used, instead of the upper-level default.

The override_domain_name_servers attribute can be specified explicitly. It is also set implicitly when domain_name_servers is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for domain_name_servers. Set the parameter to "false" to inherit the upper-level setting for domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_domain_name_servers
my $override_domain_name_servers=$ipv6fa->override_domain_name_servers( );
```

```
#Modify override_domain_name_servers
$ipv6fa->override_domain_name_servers("true");
```

override_cli_credentials( )

The override_cli_credentials attribute controls whether the cli_credentials value in the object is used, instead of the grid default.

The override_cli_credentials attribute can be specified explicitly. It is also set implicitly when cli_credentials is set to a defined value.

Parameter

Specify "true" to set the override_cli_credentials flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $ipv6fa->override_cli_credentials();
# Modify attribute value
$ipv6fa->override_cli_credentials('true');
```

override_options( )

The override_options attribute controls whether the options in the DHCP IPv6 fixed address are used, instead of the upper-level default.

The override_options attribute can be specified explicitly. It is also set implicitly when options are set to defined values.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_options
my $override_options=$ipv6fa->override_options( );
#Modify override_options
$ipv6fa->override_options("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP IPv6 fixed address is used, instead of the upper-level default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_preferred_lifetime
my $override_preferred_lifetime=$ipv6fa->override_preferred_lifetime( );
#Modify override_preferred_lifetime
$ipv6fa->override_preferred_lifetime("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the DHCP IPv6 fixed address is used, instead of the upper-level default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_valid_lifetime
my $override_valid_lifetime=$ipv6fa->override_valid_lifetime( );
#Modify override_valid_lifetime
$ipv6fa->override_valid_lifetime("true");
```

port_duplex( )

Use this method to retrieve the duplex setting of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the port duplex setting. The returned value, if any, is one of the following:

```
Full
Half
```

Example

```
#Get port_duplex
my $port_duplex = $ipv6fa->port_duplex();
```

port_link_status( )

Use this method to retrieve the link status of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

This method returns the link status of the network device port. The returned value, if any, is one of the following:

```
Connected
Not Connected
Unknown
```

Example

```
#Get port_link_status
my $port_link_status = $ipv6fa->port_link_status();
```

port_speed( )

Use this method to retrieve the speed of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the network device port speed. The returned value, if any, is one of the following:

```
10M
100M
1G
10G
100G
Unknown
```

Example

```
#Get port_speed
my $port_speed = $ipv6fa->port_speed();
```

port_status( )

Use this method to retrieve the status of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the network device port status. The returned value, if any, is one of the following:

```
Up
Down
Unknown
```

Example

```
#Get port_status
my $port_status = $ipv6fa->port_status();
```

port_vlan_description( )

Use this method to retrieve the VLAN description of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the VLAN description of the network device port.

Example

```
#Get port_vlan_description
my $port_vlan_description = $ipv6fa->port_vlan_description();
```

port_vlan_name( )

Use this method to retrieve the VLAN name of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the network device port VLAN name.

Example

```
#Get port_vlan_name
my $port_vlan_name = $ipv6fa->port_vlan_name();
```

port_vlan_number ( )

Use this method to retrieve the VLAN number of the network device port that is connected to the DHCP IPv6 Fixed Address object.

Parameter

none

Returns

The method returns the port VLAN number.

Example

```
#Get port_vlan_number
my $port_vlan_number  = $ipv6fa->port_vlan_number ();
```

preferred_lifetime( )

Use this method to set or retrieve the preferred_lifetime value of a DHCP IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_preferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(20000); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(20000); will result in override_preferred_lifetime="true".

Parameter

A 32-bit integer (valid range from 1 to 4294967295) that represents the lifetime, in seconds. The default value is 27000.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get preferred_lifetime
my $preferred_lifetime = $ipv6fa->preferred_lifetime();
#Modify preferred_lifetime
$ipv6fa->preferred_lifetime("369");
```

template( )

Use this method to set or retrieve the fixed address template name for a DHCP IPv6 Fixed Address object.

Template is the name of a DHCP IPv6 Fixed Address template which will be used to create the DHCP IPv6 Fixed Address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

The template parameter can be used to only add a new DHCP IPv6 Fixed Address and cannot be used during object modify or returned during object get.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get template
my $template = $ipv6fa->template();
#Modify template
$ipv6fa->template("Template_Name");
```

valid_lifetime( )

Use this method to set or retrieve the valid_lifetime value of a DHCP IPv6 Fixed Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 1 to 4294967295, that represents the lifetime, in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid_lifetime
my $valid_lifetime = $ipv6fa->valid_lifetime();
#Modify valid_lifetime
$ipv6fa->valid_lifetime("36900");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP IPv6 Fixed Address object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create an IPv6 network object
my $network = Infoblox::DHCP::IPv6Network->new(
                                          "network" => "2001::/64",
                                         );
unless($network) {
     die("Construct IPv6 Network object failed: ",
          Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "IPv6 Network object created successfully\n";

$session->add($network)
    or die("Add network failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Network added successfully\n";

my $option1 = Infoblox::DHCP::Option->new(
    "name"  => "dhcp6.fqdn",
    "value" => "mydomain.com"
);
unless($option1) {
    die("Construct option1 object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "option1 object created successfully\n";

my $option2 = Infoblox::DHCP::Option->new(

NAME

Infoblox::DHCP::IPv6FixedAddrTemplate - DHCP IPv6 Fixed Address Template object

---

DESCRIPTION

An IPv6 fixed address template contains a set of predefined properties and can be used to create an IPv6 fixed address object in a quick and consistent way. An IPv6 fixed address created from an IPv6 fixed address template inherits the properties defined in the template.

CONSTRUCTOR

```
my $fixed_addr_template = Infoblox::DHCP::IPv6FixedAddrTemplate -> new(
        name                          => $string,                                  #Required
        comment                       => $string,                                  #Optional / Default is
undefined
        domain_name                   => $fqdn,                                    #Optional / Default is
undefined
        domain_name_servers           => "$ipv6addr1,$ipv6addr2,...",              #Optional / Default is
undefined
        extattrs                      => { $string => $extattr, ... },             #Optional / Default is
undefined
        extensible_attributes         => { $string => $string | $num, $string => [ $string | $num, ... ],
... }, #Optional / Default is undefined
        number_of_addresses           => $num | undef,                             #Optional / Default is
undefined
        offset                        => $num | undef,                             #Optional / Default is
undefined
        options                       => [$option1, $option2],                     #Optional / Default is empty
        override_domain_name          => "true" | "false",                         #Optional / Default is
"false"
        override_domain_name_servers => "true" | "false",                          #Optional / Default is
"false"
        override_options              => "true" | "false",                         #Optional / Default is
"false"
        override_preferred_lifetime   => "true" | "false",                         #Optional / Default is
"false"
```

```
        override_valid_lifetime      => "true" | "false",                #Optional / Default is
"false"
        preferred_lifetime           => $num,                            #Optional / Default is 27000
        valid_lifetime               => $num,                            #Optional / Default is 43200
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

MODULE METHODS

The following functions can be applied to a DHCP IPv6 Fixed Address Template object.

Infoblox::DHCP::NetworkTemplate-> fixed_address_templates( )

Use this function to include a fixed address template in a network template on the Infoblox appliance. See Infoblox::DHCP::IPv6NetworkTemplate->fixed_address_templates() for parameters and return values.

Example

```
#Create the IPv6 network template that includes the IPv6 fixed address template
my $template = Infoblox::DHCP::Template->new(
  name                    => "custom_fa_template"
);
my $network_template = Infoblox::DHCP::IPv6NetworkTemplate->new(
  name                    => "custom_network_template",
  comment                 => "add network",
  fixed_address_templates => [$template]
);
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that can be applied to a DHCP IPv6 fixed address template object.

Infoblox::Session->add( )

Use this method to add a DHCP IPv6 fixed address template object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct a DHCP IPv6 Fixed Address Template object
my $fixed_addr_template = Infoblox::DHCP::IPv6FixedAddrTemplate->new(
);

#Submit for addition
my $response = $session->add($fixed_addr_template);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 Fixed Address Template object:

name - Optional. The name of the fixed address template.
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Examples

```
#Get DHCP IPv6 fixed address template object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6FixedAddrTemplate",
    name   => "custom_fa_template",
);

my @retrieved_objs = $session->get(
  object                => "Infoblox::DHCP::IPv6FixedAddrTemplate",
  extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a DHCP IPv6 Fixed Address Template object:

name    - Optional. The name of the fixed address template (regular expression).
comment - Optional. The comment of the fixed address template (regular expression).
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
#Search for a DHCP IPv6 fixed address template object through the session
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::IPv6FixedAddrTemplate",
    name    => "custom_fa_template",
    comment => ".*",
);

#Search for DHCP IPv6 Fixed Address Template objects that specify "Santa Clara" for the "Site"
extensible attribute
my @retrieved_objs = $session->search(
    object                => "Infoblox::DHCP::IPv6FixedAddrTemplate",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP IPv6 fixed address template object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify the pxe_lease_time
$fixed_addr_templateess->pxe_lease_time("1234");
#Submit modification
my $response = $session->modify( $fixed_addr_templateess );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP IPv6 fixed address template object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` to retrieve the DHCP IPv6 Fixed Address Template object, and then submit it for removal.

Example

```
#Get DHCP IPv6 fixed address template object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6FixedAddrTemplate",
    name   => "custom_fa_template",
);
#Find the desired object from the retrieved list.
my $desired_fixed_addr_template = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_fixed_addr_template );
```

METHODS

This section describes all the methods that can be used to set and retrieve the attribute values of a DHCP IPv6 Fixed Address Template object.

comment( )

Use this method to set or retrieve the descriptive comment of a DHCP IPv6 Fixed Address Template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $fixed_addr_template->comment();
#Modify comment
$fixed_addr_template->comment("Modified DHCP Fixed Address template object comment");
```

domain_name( )

Use this method to set or retrieve the domain_name value of a DHCP IPv6 Fixed Address Template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_domain_name attribute to "false".

Note that when domain_name is set to a defined value and override_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name("testdomain"); $object->override_domain_name("false"); will set override_domain_name to "false", and the sequence $object->override_domain_name("false"); $object->domain_name("testdomain"); will result in override_domain_name="true".

Parameter

The client's domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name
my $domain_name = $fixed_addr_template->domain_name();
#Modify domain_name
$fixed_addr_template->domain_name("test_domain.com");
```

domain_name_servers( )

Use this method to set or retrieve the domain_name_servers value of a DHCP IPv6 fixed address template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_domain_name_servers attribute to "false".

Note that when domain_name_servers is set to a defined value and override_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name_servers("2001::1,2001::2"); $object->override_domain_name_servers("false"); will set override_domain_name_servers to "false", and the sequence $object->override_domain_name_servers("false"); $object->domain_name_servers("2001::1,2001::2"); will result in override_domain_name_servers="true".

Parameter

Comma-separated list of the IPv6 addresses of the DNS servers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name_servers
my $domain_name_servers = $fixed_addr_template->domain_name_servers();
#Modify domain_name_servers
$fixed_addr_template->domain_name_servers("2001::1,2001::2");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP IPv6 Fixed Address Template object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $fixed_addr_template->extattrs();
#Modify extattrs
$fixed_addr_template->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP IPv6 Fixed Address Template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $fixed_addr_template->extensible_attributes();
#Modify extensible attributes
$fixed_addr_template->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

name( )

Use this method to set or retrieve the name of a DHCP IPv6 Fixed Address Template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the IPv6 fixed address template in string format and with a maximum of 64 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.
If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $fixed_address_template->name();
#Modify name
$fixed_address_template->name("custom_fa_template");
```

number_of_addresses( )

Use this method to set or retrieve the number of addresses in a DHCP IPv6 fixed address template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of addresses in this fixed address template.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.
If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get number_of_addresses
my $number_of_addresses = $fixed_address_template-> number_of_addresses();
#Modify number_of_addresses
$fixed_address_template->number_of_addresses("10");
```

offset( )

Use this method to set or retrieve the address offset of an IPv6 fixed address template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The address offset of this IPv6 fixed address template. The offset is calculated from the start address of the IPv6 network template that includes the fixed address template. For example, in the IPv6 network 2001:0:0:10::/8, if the offset is set to 10 and number_of_addresses is set to 10, then 10 fixed address objects will be created. The start address will be 2001:0:0:10::A and the end address will be 2001:0:0:10::14.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get offset
my $offset = $fixed_address_template->offset();
#Modify offset
$fixed_address_template->offset("10");
```

options( )

Use this method to set or retrieve the options of a DHCP IPv6 fixed address template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

See Infoblox::DHCP::Option for parameters and methods available for this object.

Setting this method to a defined value implicitly sets the override_options method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_options attribute to "false".

Note that when the options method is set to a defined value and override_options is set to "false", the last operation takes precedence. Thus the sequence $object->options([$opt]); $object->override_options("false"); will set override_options to "false", and the sequence $object->override_options("false"); $object->options([$opt]); will result in override_options="true".

Parameter

Options describe network configuration settings and various services available on the network. These options occur as variable-length fields at the end of DHCP messages.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $fixed_addr_template->options();
#Modify options
$fixed_addr_template->options([$option1, $option2]);
```

override_domain_name( )

The override_domain_name attribute controls whether the domain_name value in the DHCP IPv6 fixed address template is used, instead of the upper-level default.

The override_domain_name attribute can be specified explicitly. It is also set implicitly when domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for domain_name. Set the parameter to "false" to inherit the upper-level setting for domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_domain_name
my $override_domain_name=$fixed_addr_template->override_domain_name( );
#Modify override_domain_name
$fixed_addr_template->override_domain_name("true");
```

override_domain_name_servers( )

The override_domain_name_servers attribute controls whether the domain_name_servers value in the DHCP IPv6 fixed address template is used, instead of the upper-level default.

The override_domain_name_servers attribute can be specified explicitly. It is also set implicitly when domain_name_servers is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for domain_name_servers. Set the parameter to "false" to inherit the upper-level setting for domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_domain_name_servers
my $override_domain_name_servers=$fixed_addr_template->override_domain_name_servers( );
#Modify override_domain_name_servers
$fixed_addr_template->override_domain_name_servers("true");
```

override_options( )

The override_options attribute controls whether the options in the DHCP IPv6 fixed address template are used, instead of the upper-level default.

The override_options attribute can be specified explicitly. It is also set implicitly when options are set to defined values.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for options. Set the parameter to "false" to inherit the upper-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_options
my $override_options=$fixed_addr_template->override_options( );
#Modify override_options
$fixed_addr_template->override_options("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP IPv6 fixed address template is used, instead of the upper-level default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for options. Set the parameter to "false" to inherit the upper-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_preferred_lifetime
my $override_preferred_lifetime=$fixed_addr_template->override_preferred_lifetime( );
#Modifying override_preferred_lifetime
$fixed_addr_template->override_preferred_lifetime("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the DHCP IPv6 fixed address template object is used, instead of the upper-level default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_valid_lifetime
my $override_valid_lifetime=$fixed_addr_template->override_valid_lifetime( );
#Modifying override_valid_lifetime
$fixed_addr_template->override_valid_lifetime("true");
```

preferred_lifetime( )

Use this method to set or retrieve the preferred lifetime of the DHCP IPv6 fixed address template.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_preferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(20000); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(20000); will result in override_preferred_lifetime="true".

Parameter

Preferred lifetime value in seconds. The default value is 27000. Note that the preferred lifetime cannot be greater than the valid lifetime.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get preferred_lifetime
my $preferred_lifetime = $fixed_addr_template->preferred_lifetime();
#Modify preferred_lifetime
$fixed_addr_template->preferred_lifetime(12345);
```

valid_lifetime( )

Use this method to set or retrieve the valid lifetime of the DHCP IPv6 fixed address template.

Setting this method to a defined value implicitly sets the override_valid_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_valid_lifetime attribute to "false".

Note that when valid_lifetime is set to a defined value and override_valid_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->valid_lifetime(20000); $object->override_valid_lifetime("false"); will set override_valid_lifetime to "false", and the sequence $object->override_valid_lifetime("false"); $object->valid_lifetime(20000); will result in override_valid_lifetime="true".

Parameter

Valid lifetime value in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid_lifetime
my $valid_lifetime = $fixed_addr_template->valid_lifetime();
#Modify valid_lifetime
$fixed_addr_template->valid_lifetime(123456);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, get, modify, and remove. Also, this sample includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);

unless ($session) {
    die("Construct session failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $option1 = Infoblox::DHCP::Option->new(
    "name"  => "dhcp6.fqdn",
    "value" => "mydomain.com"
);
unless($option1) {
    die("Construct option1 object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "option1 object created successfully\n";

my $option2 = Infoblox::DHCP::Option->new(
    "name"     => "dhcp6.info-refresh-time",
    "value"    => "1000",
);
unless($option2) {
    die("Construct option2 object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "option2 object created successfully\n";
```

#Create a DHCP IPv6 Fixed Address Template object

```
#Create a DHCP IPv6 Fixed Address Template object
my $fixed_addr_template = Infoblox::DHCP::IPv6FixedAddrTemplate->new(
    "name"                  => "custom_fa_template",
    "comment"               => "add IPv6 fixed address template",
    "domain_name"           => "test_domain.com",
    "number_of_addresses"   => 1,
    "offset"                => 10,
    "options"               => [ $option1, $option2 ],
    "preferred_lifetime"    => 1000,
    "valid_lifetime"        => 3600,
);
unless($fixed_addr_template) {
    die("Construct IPv6 Fixed Address template failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP IPv6 Fixed Address template object created successfully\n";

#Verify if the DHCP IPv6 Fixed Address template exists in the Infoblox appliance
my $object = $session->get(
    object => "Infoblox::DHCP::IPv6FixedAddrTemplate",
    name   => "custom_fa_template"
);

unless ($object) {
    print "IPv6 Fixed Address template does not exist on server, safe to add the IPv6 fixed address
template\n";
    $session->add($fixed_addr_template)
        or die("Add IPv6 Fixed Address template failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "DHCP IPv6 Fixed Address template added successfully\n";
```

#Search for a DHCP IPv6 Fixed Address Template object

```
#Search for a DHCP IPv6 fixed address template object through the session
my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::IPv6FixedAddrTemplate",
    name   => "custom_fa_template",
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Search IPv6 Fixed Address template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search IPv6 Fixed Address template object found at least 1 matching entry\n";
```

#Get and modify a DHCP IPv6 Fixed Address Template object

```
#Get DHCP IPv6 fixed address template object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6FixedAddrTemplate",
    name   => "custom_fa_template",
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Get IPv6 Fixed Address template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get IPv6 Fixed Address template object found at least 1 matching entry\n";

#Modify one of the attributes of the obtained IPv6 Fixed Address Template object
$object->valid_lifetime(1234);

#Apply the changes
$session->modify($object)
    or die("Modify IPv6 Fixed Address template failed: ",
    $session->status_code() . ":" . $session->status_detail());

print "DHCP IPv6 Fixed Address template added successfully\n";
```

#Create the IPv6 network template object and include the IPv6 fixed address template

```
my $template = Infoblox::DHCP::Template->new(
    name => "custom_fa_template",
);
```

```
my $network_template = Infoblox::DHCP::IPv6NetworkTemplate->new(
    name     => "custom_network_template",
    comment => "add network",
    fixed_address_templates => [$template]
);

unless($network_template) {
    die("Construct Network template object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "Network template object created successfully\n";

#Add the IPv6 network template object to the Infoblox appliance through a session
my $resp = $session->add($network_template)
    or die("Add Network object failed: ",
    $session->status_code() . ":" . $session->status_detail());

print "Network template object added to Infoblox appliance successfully\n";
```

#Remove an IPv6 fixed address template object

```
#Remove an IPv6 network template object
$session->remove($network_template)
    or die("Remove Network Template template object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "Network Template object removed successfully \n";

#Get an IPv6 Fixed Address Template object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6FixedAddrTemplate",
    name   => "custom_fa_template",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get IPv6 Fixed Address template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get IPv6 Fixed Address template object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove IPv6 Fixed Address template object failed: ",
    $session->status_code() . ":" . $session->status_detail());
print "IPv6 Fixed Address template object removed successfully \n";

NAME

Infoblox::DHCP::IPv6HostAddr - DHCP IPv6 Host Address object.

DESCRIPTION

An IPv6 Host Address is an object used to specify IPv6 addresses in a DNS Host object.

CONSTRUCTOR

```
 my $host_addr = Infoblox::DHCP::IPv6HostAddr -> new(
       duid                          => $string,                       # Required
       address_type                  => "ADDRESS" | "PREFIX" | "BOTH", # Optional / Default is "ADDRESS"
       configure_for_dhcp            => "true" | "false",              # Optional / Default is "false"
                                                                       # When both the IP address and DUID
are present, the default value is "true"
                                                                       # Applicable only when adding this
host address to a host
       domain_name                   => $string,                       # Optional / Default is undefined
       domain_name_servers           => "$ipv6addr1,$ipv6addr2,...",   # Optional / Default is undefined
       ipv6addr                      => $ipv6addr,                     # Optional / one of ipv6addr or
ipv6prefix is required
       ipv6prefix                    => $ipv6addr,                     # Optional / one of ipv6addr or
ipv6prefix is required
       ipv6prefix_bits               => $ipv6addr,                     # Optional / Required if ipv6prefix
is specified
       match_client                  => $string,                       # Optional / Default is "DUID"
                                                                       # Possible values are:
                                                                       #  "DUID", "RESERVED",
       options                       => [$option1, $option2, ...]      # Optional / Default is empty
       override_domain_name          => "true" | "false",              # Optional / Default value is
"false"
       override_domain_name_servers  => "true" | "false",              # Optional / Default value is
"false"
       override_options              => "true" | "false",              # Optional / Default value is
"false"
       override_preferred_lifetime   => "true" | "false",              # Optional / Default value is
"false"
       override_valid_lifetime       => "true" | "false",              # Optional / Default value is
"false"
       preferred_lifetime            => $num,                          # Optional / Default is "27000"
       valid_lifetime                => $num,                          # Optional / Default is 43200
       use_for_ea_inheritance        => "true" | "false",              # Optional / Default value is
"false"
       reserved_interface            => $interface,                    # Optional
 );
```

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DHCP IPv6 Host Address object.

Infoblox::DNS::Host->ipv6addrs( )

Use this function to specify the addresses associated with the Host record. See Infoblox::DNS::Host->ipv6addrs() for parameters and return values.

Example

```
       #Construct a Host Address object
       my $h1 = Infoblox::DHCP::HostAddr->new(
                                          duid     => '0cc084d303010003',
                                          ipv6addr => '2001::4',
       );

       # Configure an address in the Host record object
       $host->ipv6addrs([$h1]);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
       Apply the following attributes to get a specific DHCP IPv6 Host Address object:

        comment                              - Optional. User-specified comment for the host address.
        duid                                 - Optional. DUID of the host address.
        ipv6addr                             - Optional. IPv6 address of the host address.
        network                              - Optional. Network address of the host address.
        network_view                         - Optional. Network view in which the host address is
      located. By default, all network views are searched.
        extensible_attributes                - Optional. A hash reference containing extensible
      attributes.

        discovered_duid                      - Optional. Discovered DHCPv6 UID.
```

```
  discovered_name                       - Optional. Discovered name.
  discoverer                            - Optional. Discoverer name.
  first_discovered                      - Optional. Time of the first discovery.
  last_discovered                       - Optional. Time of the last discovery.
  netbios                               - Optional. Discovered NetBIOS name.
  network_component_description         - Optional. Discovered network component description.
  network_component_ip                  - Optional. Discovered network component IP address.
  network_component_name                - Optional. Discovered network component name.
  network_component_port_description    - Optional. Discovered network component port description.
  network_component_port_name           - Optional. Discovered network component port name.
  network_component_port_number         - Optional. Discovered network component port number.
  network_component_type                - Optional. Discovered network component type.
  os                                    - Optional. Discovered OS.
  port_duplex                           - Optional. Discovered port duplex settings.
  port_link_status                      - Optional. Discovered port link status.
  port_speed                            - Optional. Discovered port speed settings.
  port_status                           - Optional. Discovered port status settings.
  port_vlan_description                 - Optional. Discovered port VLAN description.
  port_vlan_name                        - Optional. Discovered port VLAN name.
  port_vlan_number                      - Optional. Discovered port VLAN number.
```

Examples

```
#Get DHCP IPv6 Host Address object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6HostAddr",
    duid   => "0001",
);
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::IPv6HostAddr",
    ipv6addr     => "2001::1",
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP IPv6 Host Address object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the preferred_lifetime
$ipv6ha->preferred_lifetime("1234567");
#Submit modification
my $response = $session->modify( $ipv6ha );
```

Infoblox::Session->search( )

Use this method to search for DHCP IPv6 Host Address object and matching Host object with MAC address in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
  Apply the following attributes to search for a specific DHCP IPv6 Host Address object:

  comment                               - Optional. User-specified comment for the host address.
  duid                                  - Optional. DUID of the host address.
  ipv6addr                              - Optional. IPv6 address of the host address.
  network                               - Optional. Network address of the host address.
  network_view                          - Optional. Network view in which the host address is
located. By default, all network views are searched.

  discovered_duid                       - Optional. Discovered DHCPv6 UID.
  discovered_name                       - Optional. Discovered name (regular expression).
  discoverer                            - Optional. Discoverer name (regular expression).
  first_discovered                      - Optional. Time of the first discovery.
  last_discovered                       - Optional. Time of the last discovery.
  netbios                               - Optional. Discovered NetBIOS name (regular expression).
  network_component_description         - Optional. Discovered network component description (regular
expression).
  network_component_ip                  - Optional. Discovered network component IP address (regular
expression).
  network_component_name                - Optional. Discovered network component name (regular
expression).
  network_component_port_description    - Optional. Discovered network component port description
(regular expression).
  network_component_port_name           - Optional. Discovered network component port name (regular
expression).
  network_component_port_number         - Optional. Discovered network component port number.
  network_component_type                - Optional. Discovered network component type (regular
expression).
  os                                    - Optional. Discovered OS  (regular expression).
  port_duplex                           - Optional. Discovered port duplex settings.
  port_link_status                      - Optional. Discovered port link status.
  port_speed                            - Optional. Discovered port speed settings
  port_status                           - Optional. Discovered port status settings.
```

```
  port_vlan_description                - Optional. Discovered port VLAN description (regular
expression).
  port_vlan_name                       - Optional. Discovered port VLAN name (regular expression).
  port_vlan_number                     - Optional. Discovered port VLAN numbe.
```

Examples

```
 # Search for all DHCP IPv6 Host Address objects that are specified in the network "2001::/24" in the
"default" network view.
 my @retrieved_objs = $session->search(
     object       => "Infoblox::DHCP::IPv6HostAddr",
     duid         => "0001",
 );
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DHCP IPv6 Host Address object.

address_type( )

Use this method to set or retrieve the address type of a DHCP IPv6 Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "ADDRESS", "PREFIX", or "BOTH". When the address type is "ADDRESS", a value for the 'ipv6addr' member is required. When the address type is "PREFIX", values for 'ipv6prefix' and 'ipv6prefix_bits' are required. When the address type is "BOTH", values for 'ipv6addr', 'ipv6prefix', and 'ipv6prefix_bits' are all required.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address_type
my $address_type = $ipv6ha->address_type();
#Modify address_type
$ipv6ha->address_type("PREFIX");
```

configure_for_dhcp( )

Use this method to set or retrieve the configure_for_dhcp flag of a DHCP IPv6 Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the configure_for_dhcp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get configure_for_dhcp
my $configure_for_dhcp = $ipv6ha->configure_for_dhcp();
#Modify configure_for_dhcp
$ipv6ha->configure_for_dhcp("true");
```

discovered_data( )

Use this method to retrieve the discovered data of a DHCP IPv6 Host Address object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Data object.

Example

```
#Get discovered_data value
my $discovered_data = $object->discovered_data();
```

discovered_duid( )

Use this method to retrieve the discovered DHCPv6 UID (DUID) of a DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_duid
my $discovered_duid = $ipv6ha->discovered_duid();
```

discovered_name( )

Use this method to retrieve the discovered name of a DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
my $discovered_name = $ipv6ha->discovered_name();
```

discoverer( )

Use this method to retrieve the discoverer of a DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $ipv6ha->discoverer();
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $ipv6ha->discover_now_status();
```

domain_name( )

Use this method to set or retrieve the domain_name value of a DHCP IPv6 host address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_domain_name attribute to "false".

Note that when domain_name is set to a defined value and override_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name("testdomain"); $object->override_domain_name("false"); will set override_domain_name to "false", and the sequence $object->override_domain_name("false"); $object->domain_name("testdomain"); will set override_domain_name to "true".

Parameter

The client's domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name
my $domain_name = $host_addr->domain_name();
#Modify domain_name
$host_addr->domain_name("test_domain.com");
```

domain_name_servers( )

Use this method to set or retrieve the domain_name_servers value of a DHCP IPv6 host address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_domain_name_servers attribute to "false".

Note that when domain_name_servers is set to a defined value and override_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name_servers("2001::1,2001::2"); $object->override_domain_name_servers("false"); will set override_domain_name_servers to "false", and the sequence $object->override_domain_name_servers("false"); $object->domain_name_servers("2001::1,2001::2"); will set in override_domain_name_servers to "true".

Parameter

The comma-separated list of domain name server addresses in IPv6 address format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name_servers
my $domain_name_servers = $host_addr->domain_name_servers();
#Modify domain_name_servers
$host_addr->domain_name_servers("2001::1,2001::2");
```

duid( )

Use this method to set or retrieve the DHCPv6 Unique Identifier (DUID) of the IPv6 Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The DUID of the matching client in hexadecimal format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get duid
my $duid = $ipv6ha->duid();
#Modify duid
$ipv6ha->duid("1c2edfaa");
```

first_discovered( )

Use this method to retrieve the date and time that the DHCP IPv6 Host Address object was first discovered.

Parameter

none

Returns

The method returns the date and time that the DHCP IPv6 Host Address object was first discovered.

Example

```
#Get first_discovered
my $first_discovered = $ipv6ha->first_discovered();
```

ipv6addr( )

Use this method to set or retrieve the the IPv6 address of the IPv6 Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number represented as eight groups of four hexadecimal digits (i.e. two octets), with each group separated by a `colon(:)` (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Leading zeroes and groups of consecutive zeros within the value can be omitted to produce a more compact representation (example: 2001::1, ::1), and dotted-quad notations can be used to express IPv4-mapped IPv6 addresses (example: ::ffff:192.0.2.128).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6addr
my ipv6addr = $ipv6ha->ipv6addr();
#Modify ipv6addr
$ipv6ha->ipv6addr("aaaa:1111:bbbb:2222:cccc:3333:dddd:5555");
```

ipv6prefix( )

Use this method to set or retrieve the IPv6 prefix of a DHCP IPv6 Host Address object. The prefix must belong to the list of global prefixes defined in the Infoblox::Grid::DHCP object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IPv6 prefix from the list of global IPv6 prefixes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. ls.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6prefix
my $ipv6prefix = $ipv6ha->ipv6prefix();
#Modify ipv6prefix
$ipv6ha->ipv6prefix("2001::");
```

ipv6prefix_bits( )

Use this method to set or retrieve the prefix bits for the DHCP IPv6 Host Address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An unsigned integer between 2 and 128.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6prefix_bits
my $ipv6prefix_bits = $ipv6ha->ipv6prefix_bits();
#Modify ipv6prefix_bits
$ipv6ha->ipv6prefix_bits(32);
```

last_discovered( )

Use this method to retrieve the time this object was last seen by a discovery job.

The default value for this field is empty.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get last_discovered
my $last_discovered = $ipv6ha->last_discovered();
```

last_queried( )

Use this method to retrieve the time when the associated record was last queried. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_queried
my $last_queried = $ipv6ha->last_queried();
```

match_client( )

Use this method to set or retrieve the match_client value of a DHCP Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

```
match_client "DUID": The fixed IP address is leased to the matching DUID.
```

Returns

```
If you specified a parameter, the method returns true when the modification succeeds, and returns
false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.
```

Example

```
#Get match_client
my $match_client = $ipv6ha->match_client();
#Modify match_client
$ipv6ha->match_client("DUID");
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $host_addr->ms_ad_user_data();
```

name( )

Use this method to set or retrieve the name of a DHCP IPv6 Host Address object. The same name can be used for multiple host addresses.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify a name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the name
my $name = $ipv6ha->name();
#Modify the name
$ipv6ha->name("pop-server");
```

netbios( )

Use this method to retrieve the name in the NetBIOS reply that responded to a NetBIOS query.

Returns

The method returns the attribute value.

Example

```
#Get NetBIOS
my $netbios = $ipv6ha->netbios();
```

network( )

Use this method to retrieve the network value of a DHCP IPv6 Host Address object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get network value
my $value = $object->network();
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $ipv6ha->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the IP address of the network device.

Example

```
#Get network_component_ip
my $network_component_ip = $ipv6ha->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the network device name.

Example

```
#Get network_component_name
my $network_component_name = $ipv6ha->network_component_name();
```

network_component_port_description( )

Use this method to retrieve the description of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the description of the port on the network device.

Example

```
#Get network_component_port_description
my $network_component_port_description = $ipv6ha->network_component_port_description();
```

network_component_port_name( )

Use this method to retrieve the name of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the name of the port on the network device.

Example

```
#Get network_component_port_name
my $network_component_port_name = $ipv6ha->network_component_port_name();
```

network_component_port_number( )

Use this method to retrieve the number of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the network device port number.

Example

```
#Get network_component_port_number
my $network_component_port_number = $ipv6ha->network_component_port_number();
```

network_component_type( )

Use this method to retrieve the type of the network device that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the network device type.

Example

```
#Get network_component_type
my $network_component_type = $ipv6ha->network_component_type();
```

options( )

Use this method to set or retrieve the options of a DHCP IPv6 Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_options method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_options attribute to "false".

Note that when the options method is set to a defined value and override_options is set to "false", the last operation takes precedence. Thus the sequence $object->options([$opt]); $object->override_options("false"); will set override_options to "false", and the sequence $object->override_options("false"); $object->options([$opt]); will set override_options to "true".

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $ipv6ha->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name   => "dhcp6.rapid-commit",
    value  => "true"
);
$ipv6ha->options([$option1);
```

os( )

Use this method to retrieve the operating system associated with this host address.

Returns

The method returns the attribute value.

Example

```
#Get OS
my $os = $ipv6ha->os();
```

override_domain_name( )

The override_domain_name attribute controls whether the domain_name value in the DHCP IPv6 host address is used, instead of the upper-level default.

The override_domain_name attribute can be specified explicitly. It is also set implicitly when domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for domain_name. Set the parameter to "false" to inherit the upper-level setting for domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_domain_name
my $override_domain_name=$ipv6ha->override_domain_name( );
#Modify override_domain_name
$ipv6ha->override_domain_name("true");
```

override_domain_name_servers( )

The override_domain_name_servers attribute controls whether the domain_name_servers value in the DHCP IPv6 host address is used, instead of the upper-level default.

The override_domain_name_servers attribute can be specified explicitly. It is also set implicitly when domain_name_servers is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for domain_name_servers. Set the parameter to "false" to inherit the upper-level setting for domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_domain_name_servers
my $override_domain_name_servers=$ipv6ha->override_domain_name_servers( );
#Modify override_domain_name_servers
$ipv6ha->override_domain_name_servers("true");
```

override_options( )

The override_options attribute controls whether the options in the DHCP IPv6 host address are used, instead of the upper-level default.

The override_options attribute can be specified explicitly. It is also set implicitly when options are set to defined values.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_options
my $override_options=$host_addr->override_options( );
#Modify override_options
$host_addr->override_options("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP IPv6 host address is used, instead of the upper-level default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_preferred_lifetime
my $override_preferred_lifetime=$host_addr->override_preferred_lifetime( );
#Modify override_preferred_lifetime
$host_addr->override_preferred_lifetime("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the DHCP IPv6 host address is used, instead of the upper-level default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_valid_lifetime
my $override_valid_lifetime=$host_addr->override_valid_lifetime( );
#Modify override_valid_lifetime
$host_addr->override_valid_lifetime("true");
```

port_duplex( )

Use this method to retrieve the duplex setting of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the port duplex setting. The returned value, if any, is one of the following:

```
Full
Half
```

Example

```
#Get port_duplex
my $port_duplex = $ipv6ha->port_duplex();
```

port_link_status( )

Use this method to retrieve the link status of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

This method returns the link status of the network device port. The returned value, if any, is one of the following:

```
Connected
Not Connected
Unknown
```

Example

```
#Get port_link_status
my $port_link_status = $ipv6ha->port_link_status();
```

port_speed( )

Use this method to retrieve the speed of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the network device port speed. The returned value, if any, is one of the following:

```
10M
100M
1G
10G
100G
Unknown
```

Example

```
#Get port_speed
my $port_speed = $ipv6ha->port_speed();
```

port_status( )

Use this method to retrieve the status of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the network device port status. The returned value, if any, is one of the following:

```
Up
Down
Unknown
```

Example

```
#Get port_status
my $port_status = $ipv6ha->port_status();
```

port_vlan_description( )

Use this method to retrieve the VLAN description of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the VLAN description of the network device port.

Example

```
#Get port_vlan_description
my $port_vlan_description = $ipv6ha->port_vlan_description();
```

port_vlan_name( )

Use this method to retrieve the VLAN name of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the network device port VLAN name.

Example

```
#Get port_vlan_name
my $port_vlan_name = $ipv6ha->port_vlan_name();
```

port_vlan_number ( )

Use this method to retrieve the VLAN number of the network device port that is connected to the DHCP IPv6 Host Address object.

Parameter

none

Returns

The method returns the port VLAN number.

Example

```
#Get port_vlan_number
my $port_vlan_number  = $ipv6ha->port_vlan_number ();
```

preferred_lifetime( )

Use this method to set or retrieve the preferred_lifetime value of a DHCP IPv6 Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_preferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(20000); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(20000); will set override_preferred_lifetime to "true".

Parameter

A 32-bit integer (valid range from 1 to 4294967295) that represents the lifetime, in seconds. The default value is 27000.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get preferred_lifetime
my $preferred_lifetime = $ipv6ha->preferred_lifetime();
#Modify preferred_lifetime
$ipv6ha->preferred_lifetime("369");
```

reserved_interface( )

Use this method to set or retrieve the reserved discovery interface.

Parameter

Valid value is an Infoblox::Grid::Discovery::DeviceInterface object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get reserved_interface
my $reserved_interface = $ipv6ha->reserved_interface();
#Modify reserved_interface
$ipv6ha->reserved_interface($interface);
```

valid_lifetime( )

Use this method to set or retrieve the valid_lifetime value of a DHCP IPv6 Host Address object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer, from 1 to 4294967295, that represents the lifetime, in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid_lifetime
my $valid_lifetime = $ipv6ha->valid_lifetime();
#Modify valid_lifetime
$ipv6ha->valid_lifetime("36900");
```

use_for_ea_inheritance( )

Use this method to set or retrieve the flag that indicates if this host address is used for inheritable extensible attributes.

Parameter

Specify "true" to enable the flag or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get use_for_ea_inheritance
my $use_for_ea_inheritance = $ipv6ha->use_for_ea_inheritance();
#Modify use_for_ea_inheritance
$ipv6ha->use_for_ea_inheritance("true");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as search and modify. This sample also includes error handling for the operations.

#Preparation prior to a DHCP IPv6 Host Address object insertion

```
#PROGRAM STARTS: Include all the modules that will be used, note the hostaddress option
use strict;
use Infoblox qw (:hostaddress);

#Create a session to the Infoblox appliance
```

```
my $session = Infoblox::Session->new(
              master   => "192.168.1.2", #appliance host ip
              username => "admin",       #appliance user login
              password => "infoblox"     #appliance password
);

unless ($session) {

NAME

Infoblox::DHCP::IPv6Network - DHCP IPv6 Network object

DESCRIPTION

When DHCP services are configured on an appliance, a network that it serves must be defined. After a network is created, you can then create all the subnetworks individually or create a parent network that encompasses all the subnetworks. This object allows the user to create IPv6 networks. For IPv4 networks, see Infoblox::DHCP::Network object.

CONSTRUCTOR

```
  my $network = Infoblox::DHCP::IPv6Network->new(
                network                             => $ipv6_subnet/prefix,             #Required,
when creating an IPv6 network
                auto_create_reversezone             => "true" | "false",                #Optional /
Default is undefined
                comment                             => $string| undef,                  #Optional /
Default is undefined
                ddns_domainname                     => $string| undef,                  #Optional /
Default is undefined
                ddns_enable_option_fqdn             => "true" | "false" ,               #Optional /
Default is "false"
                ddns_generate_hostname              => "true" | "false" | undef,        #Optional /
Default is undefined
                ddns_server_always_updates          => "true" | "false",                #Optional /
Default is "true"
                ddns_ttl                            => $num,                            #Optional /
Default is "0"
                disable                             => "true" | "false",                #Optional /
Default is "false"
                domain_name                         => $string,                         #Optional /
Default is undefined

Default is undefined
              );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that can apply to a DHCP IPv6 Network object.

Infoblox::Session->add( )

Use this method to add an IPv6 Network object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Adding an IPv6 network.
#Construct an object
my $network = Infoblox::DHCP::IPv6Network->new(
```

```
        network => "2001::/64",
);

# Submit for adding an IPv6 network
my $response = $session->add( $network );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching IPv6 Network objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 network object:

  comment                  - Optional. A comment in string format.
  extattrs                 - Optional. A hash reference containing extensible attributes.
  extensible_attributes    - Optional. A hash reference containing extensible attributes.
  network                  - Optional. The IPv6 address and netmask of an IPv6 network in CIDR
format.
  network_view             - Optional. The network view in which the network is located. By default,
all network views are searched.
  discovered_bridge_domain - Optional. A bridge domain name in string format.
  discovered_tenant        - Optional. A tenant name in string format.
```

Examples

```
my  @result_array = $session->get(
     object       => "Infoblox::DHCP::IPv6Network" ,
     network      => "2001::/64",
     network_view => "default"
);

my  @result_array = $session->get(
     object               => "Infoblox::DHCP::IPv6Network" ,
     extensible_attributes => { 'Site' => 'Santa Clara' }
);

my  @result_array = $session->get(
     object  => "Infoblox::DHCP::IPv6Network" ,
     comment => "my-comment",
);

my @result_array = $session->get(
     object                  => "Infoblox::DHCP::IPv6Network" ,
     discovered_bridge_domain => "domain1",
);

my @result_array = $session->get(
     object           => "Infoblox::DHCP::IPv6Network" ,
     discovered_tenant => "tenant1",
);
```

Infoblox::Session->modify( )

Use this method to modify an IPv6 Network object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify comment.
$object->comment("This is a new comment");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Key References

```
remove_options - Optional. A hash reference containing the following attributes:

+-------------------------------------------------------------------------------------------+
| reason             - Optional. The reason for removing the network in string format with |
```

```
|                       a maximum of 256 bytes.                                                  |
|                       Used when 'rir_organization' attribute has been defined.                 |
| send_rir_request    - Optional. Boolean flag that indicates whether the appliance should       |
|                       send an API or email request for Regional Internet Registry (RIR).       |
|                       Used when 'rir_organization' attribute has been defined.                 |
+------------------------------------------------------------------------------------------------+
```

Example

```
 # Get the object under the same name
my  @result_array = $session->get(

       object        => "Infoblox::DHCP::IPv6Network" ,
       network       => "2001::/64",
       network_view  => "default"
         );

 # find the desired object from the retrieved list.
 my $desired_network = $result_array[0];

 # Submit for removal
 my $response = $session->remove(
     $desired_network,
     remove_options => {'reason' => 'Moved to B3', send_rir_request => 'true'} );
```

Infoblox::Session->search( )

Use this method to search for a DHCP IPv6 Network object in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
 Apply the following attributes to search for a DHCP IPv6 Network object:

  comment                  - Optional. A comment in string format (regular expression).
  extattrs                 - Optional. A hash reference containing extensible attributes.
  extensible_attributes    - Optional. A hash reference containing extensible attributes.
  network                  - Optional. The IPv6 address and netmask of an IPv6 network in CIDR
format.
  network_view             - Optional. The network view in which the network is located. By default,
all network views are searched.
  discovered_bridge_domain - Optional. A bridge domain name in string format (regular expression).
  discovered_tenant        - Optional. A tenant name in string format (regular expression).
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# search for all DHCP IPv6 Network objects
    my @retrieved_objs = $session->search(
      object       => "Infoblox::DHCP::IPv6Network",
      network      => "2001.*",
      network_view => "default"
    );

# search IPv6 network by comment
    my @retrieved_objs = $session->search(
      object    => "Infoblox::DHCP::IPv6Network",
      comment   => "my-comment",
    );

# search for all DHCP IPv6 Network objects defining "Santa Clara" for "Site" extensible attribute
    my @retrieved_objs = $session->search(
      object               => "Infoblox::DHCP::IPv6Network",
      extensible_attributes => { 'Site' => 'Santa Clara' }
    );

# search network by discovered bridge domain
 my @result_array = $session->search(
       object                   => "Infoblox::DHCP::IPv6Network" ,
       discovered_bridge_domain => "domain.*",
   );

 # search network by discovered tenant
 my @result_array = $session->search(
       object            => "Infoblox::DHCP::IPv6Network" ,
       discovered_tenant => "tenant.*",
   );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP IPv6 Network object

auto_create_reversezone( )

Use this method to set the auto_create_reversezone flag of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. This is a write-only attribute and cannot be retrieved after being set.

Parameter

Specify "true" to set the auto_create_reversezone flag or "false" to deactivate/unset it. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
# Modify auto_create_reversezone
$network_container->auto_create_reversezone("true");
```

comment( )

Use this method to set or retrieve a descriptive comment of an IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $network->comment();
# Modify comment
$network->comment("add an IPv6 network");
```

cloud_info( )

Use this method to set or retrieve cloud API related information for the Infoblox::DHCP::IPv6Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a Infoblox::Grid::CloudAPI::Info object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $network_view->cloud_info();
# Modify cloud_info
$network_view->cloud_info($cloud_info_object);
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_ddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $network->ddns_domainname();
#Modify ddns_domainname
$network->ddns_domainname("test_domain.com");
```

ddns_enable_option_fqdn( )

Use this method to set or retrieve the ddns_enable_option_fqdn flag of a DHCP IPv6 Network object. This method controls whether the FQDN option sent by the client is to be used, or if the server can automatically generate the FQDN. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_enable_option_fqdn method to "true". Setting the parameter to undefined causes the appliance to use the upper-level setting and automatically resets the override_ddns_enable_option_fqdn attribute to "false".

Note that when ddns_enable_option_fqdn is set to a defined value and override_ddns_enable_option_fqdn is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_enable_option_fqdn("true"); $object->override_ddns_enable_option_fqdn("false"); will set override_ddns_enable_option_fqdn to "false", and the sequence $object->override_ddns_enable_option_fqdn("false"); $object->ddns_enable_option_fqdn("true"); will result in override_ddns_enable_option_fqdn="true".

Parameter

Specify "true" to generate hostname or "false" to deactivate/unset it.The default value for this field is undefined, which indicates that this attribute inherit the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_enable_option_fqdn
my $ddns_enable_option_fqdn = $network->ddns_enable_option_fqdn()
# Modify ddns_enable_option_fqdn
$network->ddns_enable_option_fqdn("true");
#Un-override
$network->ddns_enable_option_fqdn(undef);
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a DHCP IPv6 Network object. Enable this method to allow only the DHCP server for generating hostname. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_generate_hostname method to "true". Setting the parameter to undefined causes the appliance to use the upper-level setting and automatically resets the override_ddns_generate_hostname attribute to "false".

Note that when ddns_generate_hostname is set to a defined value and override_ddns_generate_hostname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_generate_hostname("true"); $object->override_ddns_generate_hostname("false"); will set override_ddns_generate_hostname to "false", and the sequence $object->override_ddns_generate_hostname("false"); $object->ddns_generate_hostname("true"); will result in override_ddns_generate_hostname="true".

Parameter

Specify "true" to generate a hostname or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherits the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_generate_hostname
my $ddns_generate_hostname = $network->ddns_generate_hostname()
# Modify ddns_generate_hostname
$network->ddns_generate_hostname("true");
#Un-override
$network->ddns_generate_hostname(undef);
```

ddns_server_always_updates( )

Use this method to set or retrieve the ddns_server_always_updates flag of a DHCP IPv6 Network object. Enable this method to allow only the DHCP server to update DNS, regardless of the requests from the DHCP clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the flag that enables the DHCP server to always updates DNS or "false" to deactivate/unset it.The default value for this field is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_server_always_updates
my $ddns_server_always_updates = $network->ddns_server_always_updates()
# Modify ddns_server_always_updates
$network->ddns_server_always_updates("true");
```

ddns_ttl( )

Use this method to set or retrieve the DNS update Time to Live (TTL) value of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_ddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, that the update is cached. Zero indicates that the update is not cached. The default value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get DNS Update ttl
my $dns_ttl = $network->ddns_ttl();
#Modify DNS Update ttl
$network->ddns_ttl(1200);
```

disable( )

Use this method to set or retrieve the disable flag of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get disable
my $disable = $network->disable()
# Modify disable
$network->disable("true");
```

discovered_bridge_domain( )

Use this method to set or retrieve the discovered bridge domain name of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The desired bridge domain name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bridge domain
my $bridge_domain = $network->discovered_bridge_domain();
#Modify bridge domain
$network->discovered_bridge_domain("Domain");
```

discovered_tenant( )

Use this method to set or retrieve the discovered tenant name of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The desired tenant name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get tenant
my $tenant = $network->discovered_tenant();
#Modify tenant
$network->discovered_tenant("Tenant");
```

discovery_basic_poll_setting( )

Use this method to set or retrieve the discovery_basic_poll_setting value of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value.

Parameter

The valid value is object of the Infoblox::Grid::Discovery::BasicPollSettings manpage.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_basic_poll_setting
my $discovery_basic_poll_setting = $network->discovery_basic_poll_setting();
#Modify discovery_basic_poll_setting
$network->discovery_basic_poll_setting($poll_setting);
```

discovery_member( )

Use this method to set or retrieve the discovery_member value of a DHCP IPv6 Network object.

Parameter

The discovery member name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_member
my $discovery_member = $network->discovery_member();
#Modify discovery_member
$network->discovery_member("test.localdomain");
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $network->discover_now_status();
```

discovery_blackout_setting( )

Use this method to set or retrieve the discovery blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If port_control_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when discovery_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->discovery_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->discovery_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_blackout_setting
my $discovery_blackout_setting = $network->discovery_blackout_setting();
#Modify discovery_blackout_setting
$network->discovery_blackout_setting($blackout);
```

discovery_engine_type( )

Use this method to retrieve the DHCP IPv6 Network discovery engine type. This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value that can be 'NETMRI', 'NETWORK_INSIGHT', 'VDISCOVERY', 'UNKNOWN' or 'NONE'.

Example

```
#Get discovery_engine_type
my $discovery_engine_type = $network->discovery_engine_type();
```

domain_name( )

Use this method to set or retrieve the domain_name value of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_domain_name attribute to "false".

Note that when domain_name is set to a defined value and override_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name("testdomain"); $object->override_domain_name("false"); will set override_domain_name to "false", and the sequence $object->override_domain_name("false"); $object->domain_name("testdomain"); will result in override_domain_name="true".

Parameter

The name of the client's domain for resolving names in DNS in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name
my $domain_name = $network->domain_name();
#Modify domain_name
$network->domain_name("test_domain.com");
```

domain_name_servers( )

Use this method to set or retrieve the domain_name_servers value of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_domain_name_servers attribute to "false".

Note that when domain_name_servers is set to a defined value and override_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name_servers("2001::1,2001::2"); $object->override_domain_name_servers("false"); will set override_domain_name_servers to "false", and the sequence $object->override_domain_name_servers("false"); $object->domain_name_servers("2001::1,2001::2"); will result in override_domain_name_servers="true".

Parameter

The domain name server addresses in IPv6 address format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name_servers
my $domain_name_servers = $network->domain_name_servers();
#Modify domain_name_servers
```

```
$network->domain_name_servers("2001::1,2001::2");
```

enable_ddns( )

Use this method to set or retrieve the dynamic DNS updates flag of a DHCP IPv6 Network object. The DHCP server can send DDNS updates to DNS servers in the same grid and to external DNS servers. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_ddns method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_enable_ddns attribute to "false".

Note that when enable_ddns is set to a defined value and override_enable_ddns is set to "false", the last operation takes precedence. Thus the sequence $object->enable_ddns("true"); $object->override_enable_ddns("false"); will set override_enable_ddns to "false", and the sequence $object->override_enable_ddns("false"); $object->enable_ddns("true"); will result in override_enable_ddns="true".

Parameter

Specify "true" to set the dynamic DNS updates flag or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherit the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ddns
my $enable_ddns = $network->enable_ddns()
# Modify enable_ddns
$network->enable_ddns("true");
# Un-override enable_ddns
$network->enable_ddns(undef);
```

enable_discovery( )

Use this method to set or retrieve the enable_discovery value of a DHCP IPv6 Network object. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_discovery method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_enable_discovery attribute to "false".

Enable this flag if you want to set discovery for this object.

Parameter

Specify "true" to set the enable_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_discovery
my $enable_discovery = $network->enable_discovery();
#Modify enable_discovery
$network->enable_discovery("false");
```

enable_ifmap_publishing( )

Use this method to set or retrieve the ifmap publishing option of a DHCP IPv6 Network object. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set ifmap publishing option or "false" to deactivate/unset it. The default value is 'false', which indicates that this attribute inherits the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ifmap_publishing
my $enable_ifmap_publishing = $network->enable_ifmap_publishing()
# Modify enable_ifmap_publishing
$network->enable_ifmap_publishing("true");
# Un-override enable_ifmap_publishing
$network->enable_ifmap_publishing(undef);
```

enable_immediate_discovery( )

Use this method to set or retrieve enable_immediate_discovery value of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_immediate_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_immediate_discovery
my $enable_immediate_discovery = $network->enable_immediate_discovery();
#Modify enable_immediate_discovery
$network->enable_immediate_discovery("false");
```

endpoint_sources( )

Use this method to retrieve the list of endpoints that provide object data. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an array of Infoblox::CiscoISE::Endpoint objects.

Example

```
#Get endpoint_sources value
my $endpoint_sources = $object->endpoint_sources();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with an IPv6 Network object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $network->extattrs();
#Modify extattrs
$network->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with an IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $network->extensible_attributes();
#Modify extensible attributes
$network->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

members( )

Use this method to set or retrieve the member that serves DHCP for an IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Member objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $member1 = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
);

#Create the Network object with this member
my $network = Infoblox::DHCP::Network->new(
    network => "2001::/64",
    members => [$member1],
);
```

mgm_private( )

Use this method to set or retrieve the flag that controls whether the object should be synced to the MGM or not.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when mgm_private is set to a defined value and override_mgm_private is set to "false", the last operation takes precedence. Thus the sequence $network->mgm_private("true"); $network->override_mgm_private("false"); will set override_mgm_private to "false", and the sequence $network->override_mgm_private("false"); $network->mgm_private("true"); will result in override_mgm_private="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable synchronization of the managed Grid with the MGM or 'false' to forbid it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get mgm_private value
my $value = $object->mgm_private();

#Modify mgm_private value
$object->mgm_private('true');
```

mgm_private_overridable( )

Use this method to retrieve the flag that indicates whether the overriding of 'mgm_private' flag is allowed or not. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get mgm_private_overridable value
my $value = $object->mgm_private_overridable();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $v6network->ms_ad_user_data();
```

network( )

Use this method to retrieve the network attribute of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the address and netmask of the network in CIDR format (example: 2001::/64).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network
my $network = $network->network();
```

network_container( )

Use this method to set or retrieve the network container of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the address and netmask of the network in CIDR format (example: 2001::/64).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network container
my $network_container = $network->network_container();
#Modify network container
$network->network_container("2001::/64");
```

network_view( )

Use this method to set or retrieve the network view of the IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the network is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $network->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$network->network_view($nview);
```

next_available_ip( )

Use this method to retrieve the next available IPv6 address(es) in the network. Note that to use this method, the object MUST be retrieved through a get or search call, or created with an add call.

Parameter

The method accepts the following optional parameters:

```
  requested_num - The number of IP addresses requested. It must be a number between 1 and 20,
inclusive.
  excluded - A reference to an array of addresses to be excluded from the results.
```

Returns

This method returns the next available IPv6 address(es) in the network. If requested_num is not specified, a string with the next available address will be returned; otherwise, the method will return a reference to an array of addresses.

Within a DHCP IPv6Network object, the next available IP address(es) are the first addresses in this network that match all of the following rules:

```
   * Are not part of the passed 'excluded' parameter (if specified).
   * There is no AAAA, PTR, fixed address or host address record with this IP address
   * There is no bulk host record with this IP address
   * There is no unmanaged record with this IP address
   * The IP address is not the network or broadcast address of this network
   * The IP address is not in any IPv6 DHCP range within this network (including any exclusion range)
```

Example

```
# Retrieve a particular network
my @retrieved_objs = $session->get(
                          object   => "Infoblox::DHCP::IPv6Network",
                          network  => "10:9::/64"
);

$network = $retrieved_objs[0];

# Print the next available IPv6 address in the network
print $network->next_available_ip() . "\n";

# This will retrieve the next 10 available addresses and print the first one.
my $addressesref = $network->next_available_ip(requested_num => 10);
```

```
print @$addressesref[0] . "\n";

# This will retrieve the next 10 available addresses and exclude two addresses.
my $addressesref = $network->next_available_ip(requested_num => 10, excluded => ["10:9::2",
"10:9::3"]);
```

next_available_network( )

Use this method to retrieve the next available IPv6 network(s). Note that to use this method, the object MUST be retrieved through a get or search call, or it must have been created with an add call.

Parameter

The method accepts the following parameters:

```
  cidr - (required) The CIDR of the requested networks. It must be a number between 3 and 128,
inclusive.
  requested_num - (optional) The number of networks requested.  It must be a number between 1 and 20,
inclusive.
  excluded - (optional) A reference to an array of networks to be excluded from the results.
```

Returns

This method returns the next available IPv6 `network(s)` . If requested_num is not specified, a string with the next available network will be returned; otherwise, the method will return a reference to an array of networks.

A network cannot be returned as the next available network if it cannot be inserted; such as when any of the following conditions exist:

- It's parent network has a DHCP configuration assigned and therefore cannot be converted to a network container.

- It overlaps with an existing network or network container, regardless of whether the existing network has a greater or smaller CIDR than the requested CIDR.

- Its network address or broadcast address is used by a fixed address or a host configured for DHCP.

Example

```
# Retrieve a particular network
my @retrieved_objs = $session->get(
                          object   => "Infoblox::DHCP::IPv6Network",
                          network  => "2001::/64"
);

$network = $retrieved_objs[0];

# Print the next available IPv6 network in the network
print $network->next_available_network(cidr => 68) . "\n";

# This will retrieve the next 10 available networks and print the first one.
my $addressesref = $network->next_available_network(requested_num => 10, cidr => 68);
print @$addressesref[0] . "\n";

# This will retrieve the next 10 available networks and exclude two.
my $addressesref = $network->next_available_network(requested_num => 10, cidr => 72, excluded =>
['2001::100:0:0:0/72','2001::300:0:0:0/72']);
```

options( )

Use this method to set or retrieve the options value of a member DHCP server. DHCP options provide network configuration settings and various services available on the network for DHCP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_options method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_options attribute to "false".

Note that when the options method is set to a defined value and override_options is set to "false", the last operation takes precedence. Thus the sequence $object->options([$opt]); $object->override_options("false"); will set override_options to "false", and the sequence $object->override_options("false"); $object->options([$opt]); will result in override_options="true".

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $network->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name => "dhcp6.info-refresh-time",
    value => 60
);

$network->options([$option1]);
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP IPv6 Network is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$network->override_ddns_domainname( );
#Modifying override_ddns_domainname
$network->override_ddns_domainname("true");
```

override_ddns_enable_option_fqdn( )

The override_ddns_enable_option_fqdn attribute controls whether the ddns_enable_option_fqdn value in the DHCP IPv6 Network is used, instead of the grid default.

The override_ddns_enable_option_fqdn attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_enable_option_fqdn. Set the parameter to "false" to inherit the grid-level setting for ddns_enable_option_fqdn.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_enable_option_fqdn
my $override_ddns_enable_option_fqdn=$network->override_ddns_enable_option_fqdn( );
#Modifying override_ddns_enable_option_fqdn
$network->override_ddns_enable_option_fqdn("true");
```

override_ddns_generate_hostname( )

The override_ddns_generate_hostname attribute controls whether the ddns_generate_hostname value in the DHCP IPv6 Network is used, instead of the grid default.

The override_ddns_generate_hostname attribute can be specified explicitly. It is also set implicitly when ddns_generate_hostname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_generate_hostname. Set the parameter to "false" to inherit the grid-level setting for ddns_generate_hostname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_generate_hostname
my $override_ddns_generate_hostname=$network->override_ddns_generate_hostname( );
#Modifying override_ddns_generate_hostname
$network->override_ddns_generate_hostname("true");
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the DHCP IPv6 Network is used, instead of the grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_ttl. Set the parameter to "false" to inherit the grid-level setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_ttl
my $override_ddns_ttl=$network->override_ddns_ttl( );
#Modifying override_ddns_ttl
$network->override_ddns_ttl("true");
```

override_domain_name( )

The override_domain_name attribute controls whether the domain_name value in the DHCP IPv6 Network is used, instead of the grid default.

The override_domain_name attribute can be specified explicitly. It is also set implicitly when domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for domain_name. Set the parameter to "false" to inherit the grid-level setting for domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_domain_name
my $override_domain_name=$network->override_domain_name( );
```

```
#Modifying override_domain_name
$network->override_domain_name("true");
```

override_domain_name_servers( )

The override_domain_name_servers attribute controls whether the domain_name_servers value in the DHCP IPv6 Network is used, instead of the grid default.

The override_domain_name_servers attribute can be specified explicitly. It is also set implicitly when domain_name_servers is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for domain_name_servers. Set the parameter to "false" to inherit the grid-level setting for domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_domain_name_servers
my $override_domain_name_servers=$network->override_domain_name_servers( );
#Modifying override_domain_name_servers
$network->override_domain_name_servers("true");
```

override_blackout_setting( )

The override_blackout_setting attribute controls whether the discovery_blackout_setting and port_control_blackout_setting values in the object are used, instead of the grid default.

The override_blackout_setting attribute can be specified explicitly. It is also set implicitly when discovery_blackout_setting or port_control_blackout_setting is set to a defined value.

Parameter

Specify "true" to set the override_blackout_setting flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $network->override_blackout_setting();
# Modify attribute value
$network->override_blackout_setting('true');
```

override_enable_ddns( )

The override_enable_ddns attribute controls whether the enable_ddns value in the DHCP IPv6 Network is used, instead of the grid default.

The override_enable_ddns attribute can be specified explicitly. It is also set implicitly when enable_ddns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ddns. Set the parameter to "false" to inherit the grid-level setting for enable_ddns.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_ddns
my $override_enable_ddns=$network->override_enable_ddns( );
#Modifying override_enable_ddns
$network->override_enable_ddns("true");
```

override_enable_ifmap_publishing( )

The override_enable_ifmap_publishing controls whether the enable_ifmap_publishing in the DHCP IPv6 Network is used, instead of the grid default.

The override_enable_ifmap_publishing can be specified explicitly. It is also set implicitly when enable_ifmap_publishing is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ifmap_publishing. Set the parameter to "false" to inherit the grid-level setting for enable_ifmap_publishing.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_ifmap_publishing
my $override_enable_ifmap_publishing=$network->override_enable_ifmap_publishing( );
#Modifying override_enable_ifmap_publishing
$network->override_enable_ifmap_publishing("true");
```

override_options( )

The override_options attribute controls whether the options value in the DHCP IPv6 Network is used, instead of the grid default.

The override_options attribute can be specified explicitly. It is also set implicitly when options is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_options
my $override_options=$network->override_options( );
#Modifying override_options
$network->override_options("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP IPv6 Network is used, instead of the grid default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_preferred_lifetime
my $override_preferred_lifetime=$network->override_preferred_lifetime( );
#Modifying override_preferred_lifetime
$network->override_preferred_lifetime("true");
```

override_recycle_leases( )

The override_recycle_leases attribute controls whether the recycle_leases value in the DHCP IPv6 Network is used, instead of the grid default.

The override_recycle_leases attribute can be specified explicitly. It is also set implicitly when recycle_leases is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_recycle_leases
my $override_recycle_leases=$network->override_recycle_leases( );
#Modifying override_recycle_leases
$network->override_recycle_leases("true");
```

override_mgm_private( )

The override_mgm_private attribute controls whether the mgm_private value in the object is used, instead of the parent-level default.

The override_mgm_private attribute can be specified explicitly. It is also set implicitly when mgm_private is set to a defined value.

Note that setting override_mgm_private to 'false' sets the original 'mgm_private' value to 'false'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to 'true' to override the parent-level setting for mgm_private. Set the parameter to 'false' to inherit the parent-level setting for mgm_private.

The default value of this parameter is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get override_mgm_private value
my $value = $object->override_mgm_private( );

#Modify override_mgm_private value
$object->override_mgm_private('true');
```

override_subscribe_settings( )

The override_subscribe_settings attribute controls whether the subscribe_settings method values of the member are used, instead of the Grid default.

The override_subscribe_settings attribute can be specified explicitly. It is also set implicitly when subscribe_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for subscribe_settings. Set the parameter to "false" to inherit the Grid-level setting for subscribe_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_subscribe_settings value
my $override_subscribe_settings = $object->override_subscribe_settings( );
#Modify override_subscribe_settings value
$object->override_subscribe_settings("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP IPv6 Network is used, instead of the grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_update_dns_on_lease_renewal
my $override_update_dns_on_lease_renewal=$network->override_update_dns_on_lease_renewal( );
#Modifying override_update_dns_on_lease_renewal
$network->override_update_dns_on_lease_renewal("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the DHCP IPv6 network is used, instead of the grid default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_valid_lifetime
my $override_valid_lifetime=$network->override_valid_lifetime( );
#Modifying override_valid_lifetime
$network->override_valid_lifetime("true");
```

preferred_lifetime ( )

Use this method to set or retrieve the preferred lifetime value of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_preferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(691200); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(691200); will result in override_preferred_lifetime="true".

Parameter

A 32-bit integer (valid range from 1 to 4294967295) that represents the lifetime, in seconds. The default value is 27000.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get Preferred lifetime
my $preferred_lifetime = $network->preferred_lifetime();
#Modify Preferred lifetime
$network->preferred_lifetime(864000);
```

port_control_blackout_setting

Use this method to set or retrieve the port control blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when port_control_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->port_control_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->port_control_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get port_control_blackout_setting
my $port_control_blackout_setting = $network->port_control_blackout_setting();
#Modify port_control_blackout_setting
$network->port_control_blackout_setting($blackout);
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag at the network level.

If the flag is enabled, the leases are kept in the recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Setting this method to a defined value implicitly sets the override_recycle_leases method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_recycle_leases attribute to "false".

Note that when recycle_leases is set to a defined value and override_recycle_leases is set to "false", the last operation takes precedence. Thus the sequence $object->recycle_leases("true"); $object->override_recycle_leases("false"); will set override_recycle_leases to "false", and the sequence $objct->override_recycle_leases("false"); $object->recycle_leases("true"); will result in override_recycle_leases="true".

Parameter

Specify "true" to enable the recycle_leases flag or "false" to disable it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $network->recycle_leases();
#Modify recycle_leases
$network->recycle_leases("false");
```

restart_if_needed( )

Use this method to set the flag that indicates whether DHCP service should be restarted on a member that is serving DHCP for the changed object referenced in a cloud API request.

Parameter

Specify true to restart the DHCP service.

Returns

None

Example

```
# Modify
$network->restart_if_needed('true');
```

rir( )

Use this method to retrieve the name of the Regional Internet Registry (RIR) that allocated this address space. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'RIPE' or 'NONE'.

Example

```
#Get rir
my $rir = $network->rir();
```

rir_organization( )

Use this method to set or retrieve the Regional Internet Registry (RIR) organization object.

Parameter

An Infoblox::Grid::RIR::Organization object.

You must enable support for RIR/SWIP at the Grid level before you can set attribute values. See Infoblox::Grid->enable_rir_swip() method.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_organization
my $rir_organization = $network->rir_organization();
#Modify rir_organization
$network->rir_organization($rir_org);
```

rir_registration_action( )

Use this method to set the registration action of Regional Internet Registry (RIR). This is a write-only attribute.

Parameter

Valid values are 'NONE', 'CREATE', 'MODIFY' or 'DELETE'.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set rir_registration_action
$network->rir_registration_action('CREATE');
```

rir_registration_status( )

Use this method to set or retrieve the registration status of Regional Internet Registry (RIR).

Parameter

The registration status of Regional Internet Registry (RIR), which can be 'REGISTERED' or 'NOT_REGISTERED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_registration_status
my $rir_registration_status = $network->rir_registration_status();
#Modify rir_registration_status
$network->rir_registration_status('NOT_REGISTERED');
```

last_rir_registration_update_sent( )

Use this method to retrieve the last registration update timestamp of Regional Internet Registry (RIR). This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_rir_registration_update_sent
my $last_rir_registration_update_sent = $network->last_rir_registration_update_sent();
```

last_rir_registration_update_status( )

Use this method to retrieve the last registration update status of Regional Internet Registry (RIR). This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_rir_registration_update_status
my $last_rir_registration_update_status = $network->last_rir_registration_update_status();
```

same_port_control_discovery_blackout( )

Use this method to set or retrieve the flag that enables using the same discovery blackout for port control blackout.

Parameter

Specify 'true' to use same discovery blackout for port control blackout or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $network->same_port_control_discovery_blackout();
# Modify attribute value
$network->same_port_control_discovery_blackout('true');
```

send_rir_request( )

Use this method to set the flag that indicates whether the appliance should send an API or email request for Regional Internet Registry (RIR). This is a write-only attribute.

Parameter

Specify "true" to set the send_rir_request flag or "false" to unset it.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set send_rir_request
$network->send_rir_request('true');
```

delete_reason( )

Use this method to specify the reason for deleting the Regional Internet Registry (RIR) registration request. This is a write-only attribute. This field is required only if 'rir_registration_action' is specified as 'DELETE'.

Parameter

The reason for deleting the RIR registration request in string format with a maximum of 256 bytes.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set delete_reason
$network->delete_reason('invalid');
```

shared_network_name( )

Use this method to retrieve the name of the shared network associated with the DHCP IPv6 Network object.

Parameter

none

Returns

The method returns the name of shared network.

Example

```
#Get shared_network_name
my $shared_network_name = $network->shared_network_name();
```

subscribe_settings( )

Use this method to set or retrieve the Cisco ISE subscribe settings.

Setting this method to a defined value implicitly sets the override_subscribe_settings method to "true". Setting the parameter to

undefined causes the appliance to use the Cisco ISE endpoint default and automatically resets the override_subscribe_settings method to "false".

Note that when subscribe_settings is set to a defined value and override_subscribe_settings is set to "false", the last operation takes precedence. Thus the sequence $object->subscribe_settings($value); $object->override_subscribe_settings("false"); will set override_subscribe_settings to "false", and the sequence $object->override_subscribe_settings("false"); $object->subscribe_settings($value); will result in override_subscribe_settings="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::CiscoISE::SubscribeSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscribe_settings value
my $subscribe_settings = $object->subscribe_settings();
#Modify subscribe_settings value
$object->subscribe_settings($settings);
```

template( )

Use this method to set or retrieve the network template name of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get template
my $template = $network->template();
#Modify template
$network->template("Template_Name");
```

unmanaged( )

Use this method to set or retrieve the network status, which indicates whether the network is unmanaged or not.

Parameter

Specify true to mark the network as unmanaged or false as managed.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get network status
$unmanaged = $network->unmanaged();
# Modify network status
$network->unmanaged('true');
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_update_dns_on_lease_renewal attribute to

"false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$network->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$network->update_dns_on_lease_renewal("true");
```

valid_lifetime ( )

Use this method to set or retrieve the valid lifetime value of a DHCP IPv6 Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_valid_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_valid_lifetime attribute to "false".

Note that when valid_lifetime is set to a defined value and override_valid_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->valid_lifetime(691200); $object->override_valid_lifetime("false"); will set override_valid_lifetime to "false", and the sequence $object->override_valid_lifetime("false"); $object->valid_lifetime(691200); will result in override_valid_lifetime="true".

Parameter

A 32-bit integer (valid range from 1 to 4294967295) that represents the valid lifetime, in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid lifetime
my $valid_lifetime = $network->valid_lifetime();
#Modify valid lifetime
$network->valid_lifetime(864000);
```

zone_associations( )

Use this method to set or retrieve the associated zone information.

Parameter

The valid value is an array reference that contains Infoblox::DNS::Zone object(s). The default value is an empty list. If the network has a parent, it is possible to use the zone associations of the parent by setting the parameter to undef.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Examples

```
#Getting zone associations
my $zone_associations = $network->zone_associations();
my $zone1 = Infoblox::DNS::Zone->new(
        name      => "test1.com",
);
my $zone2 = Infoblox::DNS::Zone->new(
```

```
            name     => "test2.com",
        );
    #Modifying zone_associations
    $network->zone_associations([$zone1, $zone2]);
    #Clear zone_assocations
    $network->zone_associations([]);
    ##Remove the override for zone_associations
    $network->zone_associations(undef)
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP IPv6 Network insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP IPv6 Network object

```
my  $network = Infoblox::DHCP::IPv6Network->new(
              network => "2001::/64",
              comment => "add network",
            );

my $response = $session->add($network)
       or die("Add Network failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Network added successfully\n";

#Search for a specific Network

#Search the network
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::IPv6Network",
    network => "2001.*"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search Network failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search Network found at least 1 matching entry\n";
```

#Get and modify a Network attribute

```
#Get IPv6 Network through the session
my @retrieved_objs = $session->get(
           object =>"Infoblox::DHCP::IPv6Network" ,
           network => "2001::"
        );

my $object = $retrieved_objs[0];

unless ($object) {
    die("Get Network object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Network found at least 1 matching entry\n";
```

#Modify one of the attributes of the specified IPv6 Network

```
$object->comment("This is a new comment"); #Apply the changes

$session->modify($object)
    or die("Modify Network attribute failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "Network object modified successfully \n";
```

#Remove an IPv6 Network Object

```
 #Get IPv6 Network object through the session
 my @retrieved_objs = $session->get(
           object  => "Infoblox::DHCP::IPv6Network" ,
           network => "2001::"
       );

   my $object = $retrieved_objs[0];

   unless ($object) {
    die("Get Network object failed: ",
        $session->status_code() . ":" . $session->status_detail());
    }

print "Get Network object found at least 1 matching entry\n";
```

#Submit the object for removal

```
$session->remove($object)
    or die("Remove Network failed: ",
        $session->status_code() . ":" . $session->status_detail());

print "Network removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::IPv6NetworkContainer - DHCP IPv6 Network Container object

DESCRIPTION

A network can contain child networks. The network that contains the child network is called a network container. This object encapsulates an IPv6 network container object.

CONSTRUCTOR

```
  my $network = Infoblox::DHCP::IPv6NetworkContainer->new(
                network                          => $ipv6_subnet/prefix,               #Required, when
creating a network container
                auto_create_reversezone          => "true" | "false",                  #Optional / Default
is "false"
                comment                          => $string| undef,                    #Optional / Default
is undefined
                remove_subnets                   => "true" | "false",                  #Optional / Default
is undefined
                rir_organization                 => $rir_org,                          #Optional / An
Infoblox::Grid::RIR::Organization object
                rir_registration_action          => 'NONE' | 'CREATE' | 'MODIFY' | 'DELETE',  # Optional /
write-only
                rir_registration_status          => 'NOT_REGISTERED' | 'REGISTERED',   #Optional / Default
is 'NOT_REGISTERED'
                send_rir_request                 => 'true' | 'false',                  #Optional / write-
only
                delete_reason                    => $string,                           #Optional / write-
only
                                                                                       #Required only if
'rir_registration_action' is specified as 'DELETE'
                mgm_private                      => "true" | "false",                  #Optional / Default
is "false"
                network_container                => $ipv6_subnet/prefix,               #Optional / Default
is "/"
                network_view                     => $NetworkView,                      #Optional / Default
is the system-defined default network view
                zone_associations                => [$zone1, $zone2, ... ] | undef,    #Optional / Default
is an empty list

                override_ddns_ttl                   => "true" | "false",                  #Optional /
Default value is "false"
                override_domain_name                => "true" | "false",                  #Optional /
Default value is "false"
                override_domain_name_servers        => "true" | "false",                  #Optional /
Default value is "false"
                override_enable_ddns                => "true" | "false",                  #Optional /
Default value is "false"
                override_mgm_private                => "true" | "false",                  #Optional /
Default value is "false"
                override_options                    => "true" | "false",                  #Optional /
Default value is "false"
                override_preferred_lifetime         => "true" | "false",                  #Optional /
Default value is "false"
                override_recycle_leases             => "true" | "false",                  #Optional /
Default value is "false"
                override_update_dns_on_lease_renewal  => "true" | "false",                #Optional /
Default value is "false"
                override_valid_lifetime             => "true" | "false",                  #Optional /
Default value is "false"
                preferred_lifetime                  => $num,                              #Optional /
Default is "27000"
                recycle_leases                      => "true" | "false" | undef,          #Optional /
Default is undefined
                update_dns_on_lease_renewal         => "true" | "false",                  #Optional /
Default value is "false"
                valid_lifetime                      => $num,                              #Optional /
Default is "43200"
                subscribe_settings          => $subscribe_settings,                       #Optional /
Default is undefined
                override_subscribe_settings => 'true' | 'false',                          #Optional /
Default is 'false'
                discovery_engine_type       => 'NETMRI' | 'NETWORK_INSIGHT' | 'VDISCOVERY' | 'UNKNOWN' |
'NONE', #Optional / Default is 'NONE'
                                );
```

You cannot set both extattrs and extensible_attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a DHCP IPv6 Network Container object.

Infoblox::Session->add( )

Use this method to add a DHCP IPv6 Network Container object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Adding an IPv6 network container.
#Construct an object
my $network_container = Infoblox::DHCP::IPv6NetworkContainer->new(
        network => "2001::/64",
);

# Submit for adding a network container
my $response = $session->add( $network_container );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching DHCP IPv6 Network Container objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 Network Container object:
```

```
  network               - Optional. The IPv6 address and netmask of a network in CIDR format.
  network_view          - Optional. The network view in which the network is located. By default, all
network views are searched.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  comment               - Optional. A comment in string format.
```

Examples

```
my  @result_array = $session->get(
     object        => "Infoblox::DHCP::IPv6NetworkContainer",
     network       => "2001::/64",
     network_view  => "default"
);

my  @result_array = $session->get(
     object                => "Infoblox::DHCP::IPv6NetworkContainer",
     extensible_attributes => { 'Site' => 'Santa Clara' }
);

my  @result_array = $session->get(
     object  => "Infoblox::DHCP::IPv6NetworkContainer",
     comment => "my-comment",
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP IPv6 Network Container object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify comment.
$network_container->comment("modified comment");
# Submit modification
my $response = $session->modify( $network_container );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Key References

```
remove_options - Optional. A hash reference containing the following attributes:

+-------------------------------------------------------------------------------------------+
| reason              - Optional. The reason for removing the network container in string   |
|                       format with a maximum of 256 bytes.                                 |
|                       Used when 'rir_organization' attribute has been defined.            |
| send_rir_request    - Optional. Boolean flag that indicates whether the appliance should |
|                       send an API or email request for Regional Internet Registry (RIR).  |
|                       Used when 'rir_organization' attribute has been defined.            |
+-------------------------------------------------------------------------------------------+
```

Example

```
 # Get the object under the same name
my  @result_array = $session->get(

      object        => "Infoblox::DHCP::IPv6NetworkContainer" ,
      network       => "2001::/64",
      network_view  => "default"
        );

# Find the desired object in the retrieved list.
my $network_container = $result_array[0];

# Submit for removal
my $response = $session->remove(
    $network_container,
    remove_options => {'reason' => 'Moved to B3', send_rir_request => 'true'} );
```

Infoblox::Session->search( )

Use this method to search for a DHCP IPv6 Network Container object in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
 Apply the following attributes to search for a DHCP IPv6 Network Container object:

  network              - Optional. The IPv6 address and netmask of a network in CIDR format (regular
expression).
  network_view         - Optional. The network view in which the network is located. By default, all
network views are searched.
  extattrs             - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  comment              - Optional. A comment in string format (regular expression).
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
 # search for all DHCP IPv6 Network Container objects
     my @retrieved_objs = $session->search(
       object       => "Infoblox::DHCP::IPv6NetworkContainer",
       network      => "2001.*",
       network_view => "default"
     );

 # search network by comment
     my @retrieved_objs = $session->search(
       object    => "Infoblox::DHCP::IPv6NetworkContainer",
       comment   => "my-comment",
     );

 # search for all DHCP IPv6 Network Container objects defining "Santa Clara" for "Site" extensible
attribute
     my @retrieved_objs = $session->search(
       object                => "Infoblox::DHCP::IPv6NetworkContainer",
       extensible_attributes => { 'Site' => 'Santa Clara' }
     );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP IPv6 Network Container object.

auto_create_reversezone( )

Use this method to set the auto_create_reversezone flag of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. This is a write-only attribute and cannot be retrieved after it is set.

Parameter

Specify "true" to set the auto_create_reversezone flag or "false" to deactivate/unset it. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
 # Modify auto_create_reversezone
 $network_container->auto_create_reversezone("true");
```

comment( )

Use this method to set or retrieve a descriptive comment for a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network container in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $network_container->comment();
# Modify comment
$network_container->comment("add a network");
```

cloud_info( )

Use this method to set or retrieve cloud API related information for the Infoblox::DHCP::IPv6NetworkContainer object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a Infoblox::Grid::CloudAPI::Info object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $network_view->cloud_info();
# Modify cloud_info
$network_view->cloud_info($cloud_info_object);
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_ddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $network_container->ddns_domainname();
#Modify ddns_domainname
$network_container->ddns_domainname("test_domain.com");
```

ddns_enable_option_fqdn( )

Use this method to set or retrieve the ddns_enable_option_fqdn flag of a DHCP IPv6 Network Container object. This method controls whether the FQDN option sent by the client is to be used, or if the server can automatically generate the FQDN. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_enable_option_fqdn method to "true". Setting the parameter to undefined causes the appliance to use the upper-level setting and automatically resets the override_ddns_enable_option_fqdn attribute to "false".

Note that when ddns_enable_option_fqdn is set to a defined value and override_ddns_enable_option_fqdn is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_enable_option_fqdn("true"); $object->override_ddns_enable_option_fqdn("false"); will set override_ddns_enable_option_fqdn to "false", and the sequence $object->override_ddns_enable_option_fqdn("false"); $object->ddns_enable_option_fqdn("true"); will result in override_ddns_enable_option_fqdn="true".

Parameter

Specify "true" to generate hostname or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherits the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_enable_option_fqdn
my $ddns_enable_option_fqdn = $network_container->ddns_enable_option_fqdn()
# Modify ddns_enable_option_fqdn
$network_container->ddns_enable_option_fqdn("true");
#Un-override
$network_container->ddns_enable_option_fqdn(undef);
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a DHCP IPv6 Network Container object. Enable this method to allow only the DHCP server for generating hostname. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_generate_hostname method to "true". Setting the parameter to undefined causes the appliance to use the upper-level setting and automatically resets the override_ddns_generate_hostname attribute to "false".

Note that when ddns_generate_hostname is set to a defined value and override_ddns_generate_hostname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_generate_hostname("true"); $object->override_ddns_generate_hostname("false"); will set override_ddns_generate_hostname to "false", and the sequence $object->override_ddns_generate_hostname("false"); $object->ddns_generate_hostname("true"); will result in override_ddns_generate_hostname="true".

Parameter

Specify "true" to generate a hostname or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherits the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_generate_hostname
my $ddns_generate_hostname = $network_container->ddns_generate_hostname()
# Modify ddns_generate_hostname
$network_container->ddns_generate_hostname("true");
#Un-override
$network_container->ddns_generate_hostname(undef);
```

ddns_server_always_updates( )

Use this method to set or retrieve the ddns_server_always_updates flag of a DHCP IPv6 Network Container object. Enable this method to allow only the DHCP server to update DNS, regardless of the requests from the DHCP clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the flag that enables the DHCP server to always updates DNS or "false" to deactivate/unset it.The default value for this field is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_server_always_updates
my $ddns_server_always_updates = $network_container->ddns_server_always_updates()
# Modify ddns_server_always_updates
```

```
$network_container->ddns_server_always_updates("true");
```

ddns_ttl( )

Use this method to set or retrieve the DNS update Time to Live (TTL) value of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_ddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, the update is cached. Zero indicates that the update is not cached. The default value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get DNS Update ttl
my $dns_ttl = $network_container->ddns_ttl();
#Modify DNS Update ttl
$network_container->ddns_ttl(1200);
```

discovery_basic_poll_setting( )

Use this method to set or retrieve the discovery_basic_poll_setting value of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value.

Parameter

The valid value is object of the Infoblox::Grid::Discovery::BasicPollSettings manpage.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_basic_poll_setting
my $discovery_basic_poll_setting = $network->discovery_basic_poll_setting();
#Modify discovery_basic_poll_setting
$network->discovery_basic_poll_setting($poll_setting);
```

discovery_member( )

Use this method to set or retrieve the discovery_member value of a DHCP IPv6 Network Container object.

Parameter

The discovery member name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_member
my $discovery_member = $network->discovery_member();
#Modify discovery_member
$network->discovery_member("test.localdomain");
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $network->discover_now_status();
```

discovery_blackout_setting( )

Use this method to set or retrieve the discovery blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If port_control_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when discovery_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->discovery_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->discovery_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_blackout_setting
my $discovery_blackout_setting = $network->discovery_blackout_setting();
#Modify discovery_blackout_setting
$network->discovery_blackout_setting($blackout);
```

discovery_engine_type( )

Use this method to retrieve the DHCP IPv6 Network Container discovery engine type. This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value that can be 'NETMRI', 'NETWORK_INSIGHT', 'VDISCOVERY', 'UNKNOWN' or 'NONE'.

Example

```
#Get discovery_engine_type
my $discovery_engine_type = $network_container->discovery_engine_type();
```

domain_name( )

Use this method to set or retrieve the domain_name value of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_domain_name attribute to "false".

Note that when domain_name is set to a defined value and override_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name("testdomain"); $object->override_domain_name("false"); will set override_domain_name to "false", and the sequence $object->override_domain_name("false"); $object->domain_name("testdomain"); will result in override_domain_name="true".

Parameter

The name of the client domain in string format for resolving names in DNS.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name
my $domain_name = $network_container->domain_name();
#Modify domain_name
$network_container->domain_name("test_domain.com");
```

domain_name_servers( )

Use this method to set or retrieve the domain_name_servers value of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_domain_name_servers attribute to "false".

Note that when domain_name_servers is set to a defined value and override_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name_servers("2001::1,2001::2"); $object->override_domain_name_servers("false"); will set override_domain_name_servers to "false", and the sequence $object->override_domain_name_servers("false"); $object->domain_name_servers("2001::1,2001::2"); will result in override_domain_name_servers="true".

Parameter

The IPv6 addresses of the domain name servers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name_servers
my $domain_name_servers = $network_container->domain_name_servers();
#Modify domain_name_servers
$network_container->domain_name_servers("2001::1,2001::2");
```

enable_ddns( )

Use this method to set or retrieve the dynamic DNS updates flag of a DHCP IPv6 Network Container object. The DHCP server can send DDNS updates to DNS servers in the same Grid and to external DNS servers. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_ddns method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_enable_ddns attribute to "false".

Note that when enable_ddns is set to a defined value and override_enable_ddns is set to "false", the last operation takes precedence. Thus the sequence $object->enable_ddns("true"); $object->override_enable_ddns("false"); will set override_enable_ddns to "false", and the sequence $object->override_enable_ddns("false"); $object->enable_ddns("true"); will result in override_enable_ddns="true".

Parameter

Specify "true" to set the dynamic DNS updates flag or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherits the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ddns
my $enable_ddns = $network_container->enable_ddns()
# Modify enable_ddns
```

```
$network_container->enable_ddns("true");
# Un-override enable_ddns
$network_container->enable_ddns(undef);
```

enable_discovery( )

Use this method to set or retrieve the enable_discovery value of a DHCP IPv6 Network Container object. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_discovery method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_enable_discovery attribute to "false".

Enable this flag if you want to set discovery for this object.

Parameter

Specify "true" to set the enable_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_discovery
my $enable_discovery = $network->enable_discovery();
#Modify enable_discovery
$network->enable_discovery("false");
```

enable_immediate_discovery( )

Use this method to set or retrieve enable_immediate_discovery value of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_immediate_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_immediate_discovery
my $enable_immediate_discovery = $network->enable_immediate_discovery();
#Modify enable_immediate_discovery
$network->enable_immediate_discovery("false");
```

endpoint_sources( )

Use this method to retrieve the list of endpoints that provide object data. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an array of Infoblox::CiscoISE::Endpoint objects.

Example

```
#Get endpoint_sources value
my $endpoint_sources = $object->endpoint_sources();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP IPv6 Network Container object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $network_container->extattrs();
#Modify extattrs
$network_container->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP IPv6 Network Container object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $network_container->extensible_attributes();
#Modify extensible attributes
$network_container->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

mgm_private( )

Use this method to set or retrieve the flag that controls whether the object should be synced to the MGM or not.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when mgm_private is set to a defined value and override_mgm_private is set to "false", the last operation takes precedence. Thus the sequence $network->mgm_private("true"); $network->override_mgm_private("false"); will set override_mgm_private to "false", and the sequence $network->override_mgm_private("false"); $network->mgm_private("true"); will result in override_mgm_private="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable synchronization of the managed Grid with the MGM or 'false' to forbid it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get mgm_private value
my $value = $object->mgm_private();

#Modify mgm_private value
$object->mgm_private('true');
```

mgm_private_overridable( )

Use this method to retrieve the flag that indicates whether the overriding of 'mgm_private' flag is allowed or not. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get mgm_private_overridable value
my $value = $object->mgm_private_overridable();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $v6network_container->ms_ad_user_data();
```

network( )

Use this method to retrieve the network attribute of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the address and netmask of the network in CIDR format (example: 2001::/64).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network
my $network = $network_container->network();
```

network_container( )

Use this method to set or retrieve the network container of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the address and netmask of the network in CIDR format (example: 2001::/64).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network container
```

```
my $network_container = $network->network_container();
#Modify network container
$network->network_container("2001::/64");
```

network_view( )

Use this method to set or retrieve the network view of the DHCP IPv6 network container.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the system-defined default network view, which means the network is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $network_container->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$network_container->network_view($nview);
```

next_available_network( )

Use this method to retrieve the next available IPv6 `network(s)` in the network container. Note that to use this method, the object MUST be retrieved through a get or search call, or it must have been created with an add call.

Parameter

The method accepts the following parameters:

```
  cidr - (required) The CIDR of the requested networks. It must be a number between 3 and 128,
inclusive.
  requested_num - (optional) The number of networks requested. It must be a number between 1 and 20,
inclusive.
  excluded - (optional) A reference to an array of networks to be excluded from the results.
```

Returns

This method returns the next available IPv6 `network(s)` in the network container. If requested_num is not specified, a string with the next available network will be returned; otherwise, the method will return a reference to an array of networks.

A network cannot be returned as the next available network if it cannot be inserted; such as when any of the following conditions exist:

- It's parent network has a DHCP configuration assigned and therefore cannot be converted to a network container.

- It overlaps with an existing network or network container, regardless of whether the existing network has a greater or smaller CIDR than the requested CIDR.

- Its network address or broadcast address is used by a fixed address or a host configured for DHCP.

Example

```
# Retrieve a particular network container
my @retrieved_objs = $session->get(
                        object   => "Infoblox::DHCP::IPv6NetworkContainer",
                        network  => "2001::/64"
);

$network_container = $retrieved_objs[0];

# Print the next available IPv6 network in the network container
print $network_container->next_available_network(cidr => 68) . "\n";

# This will retrieve the next 10 available networks and print the first one.
my $addressesref = $network_container->next_available_network(requested_num => 10, cidr => 68);
print @$addressesref[0] . "\n";

# This will retrieve the next 10 available networks and exclude two.
my $addressesref = $network_container->next_available_network(requested_num => 10, cidr => 72,
excluded => ['2001::100:0:0:0/72','2001::300:0:0:0/72']);
```

options( )

Use this method to set or retrieve the option values for a member DHCP server. DHCP options provide Network Container configuration settings and various services available for the Network Container.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_options method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_options attribute to "false".

Note that when the options method is set to a defined value and override_options is set to "false", the last operation takes precedence. Thus the sequence $object->options([$opt]); $object->override_options("false"); will set override_options to "false", and the sequence $object->override_options("false"); $object->options([$opt]); will result in override_options="true".

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $network_container->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name => "dhcp6.info-refresh-time",
    value => 60
);

$network_container->options([$option1]);
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the Grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$network_container->override_ddns_domainname( );
#Modifying override_ddns_domainname
$network_container->override_ddns_domainname("true");
```

override_ddns_enable_option_fqdn( )

The override_ddns_enable_option_fqdn attribute controls whether the ddns_enable_option_fqdn value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_ddns_enable_option_fqdn attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for ddns_enable_option_fqdn. Set the parameter to "false" to inherit the Grid-level setting for ddns_enable_option_fqdn.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_enable_option_fqdn
my $override_ddns_enable_option_fqdn=$network_container->override_ddns_enable_option_fqdn( );
#Modifying override_ddns_enable_option_fqdn
$network_container->override_ddns_enable_option_fqdn("true");
```

override_ddns_generate_hostname( )

The override_ddns_generate_hostname attribute controls whether the ddns_generate_hostname value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_ddns_generate_hostname attribute can be specified explicitly. It is also set implicitly when ddns_generate_hostname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for ddns_generate_hostname. Set the parameter to "false" to inherit the Grid-level setting for ddns_generate_hostname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_generate_hostname
my $override_ddns_generate_hostname=$network_container->override_ddns_generate_hostname( );
#Modifying override_ddns_generate_hostname
$network_container->override_ddns_generate_hostname("true");
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for ddns_ttl. Set the parameter to "false" to inherit the Grid-level setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_ttl
my $override_ddns_ttl=$network_container->override_ddns_ttl( );
#Modifying override_ddns_ttl
$network_container->override_ddns_ttl("true");
```

override_domain_name( )

The override_domain_name attribute controls whether the domain_name value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_domain_name attribute can be specified explicitly. It is also set implicitly when domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for domain_name. Set the parameter to "false" to inherit the Grid-level setting for domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_domain_name
my $override_domain_name=$network_container->override_domain_name( );
#Modifying override_domain_name
$network_container->override_domain_name("true");
```

override_domain_name_servers( )

The override_domain_name_servers attribute controls whether the domain_name_servers value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_domain_name_servers attribute can be specified explicitly. It is also set implicitly when domain_name_servers is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for domain_name_servers. Set the parameter to "false" to inherit the Grid-level setting for domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_domain_name_servers
my $override_domain_name_servers=$network_container->override_domain_name_servers( );
#Modifying override_domain_name_servers
$network_container->override_domain_name_servers("true");
```

override_blackout_setting( )

The override_blackout_setting attribute controls whether the discovery_blackout_setting and port_control_blackout_setting values in the object are used, instead of the Grid default.

The override_blackout_setting attribute can be specified explicitly. It is also set implicitly when discovery_blackout_setting or port_control_blackout_setting is set to a defined value.

Parameter

Specify "true" to set the override_blackout_setting flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $network->override_blackout_setting();
```

```
# Modify attribute value
$network->override_blackout_setting('true');
```

override_enable_ddns( )

The override_enable_ddns attribute controls whether the enable_ddns value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_enable_ddns attribute can be specified explicitly. It is also set implicitly when enable_ddns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for enable_ddns. Set the parameter to "false" to inherit the Grid-level setting for enable_ddns.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_ddns
my $override_enable_ddns=$network_container->override_enable_ddns( );
#Modifying override_enable_ddns
$network_container->override_enable_ddns("true");
```

override_options( )

The override_options attribute controls whether the options value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_options attribute can be specified explicitly. It is also set implicitly when options is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for options. Set the parameter to "false" to inherit the Grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_options
my $override_options=$network_container->override_options( );
#Modifying override_options
$network_container->override_options("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for options. Set the parameter to "false" to inherit the Grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_preferred_lifetime
my $override_preferred_lifetime=$network_container->override_preferred_lifetime( );
#Modifying override_preferred_lifetime
$network_container->override_preferred_lifetime("true");
```

override_recycle_leases( )

The override_recycle_leases attribute controls whether the recycle_leases value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_recycle_leases attribute can be specified explicitly. It is also set implicitly when recycle_leases is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for options. Set the parameter to "false" to inherit the Grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_recycle_leases
my $override_recycle_leases=$network_container->override_recycle_leases( );
#Modifying override_recycle_leases
$network_container->override_recycle_leases("true");
```

override_mgm_private( )

The override_mgm_private attribute controls whether the mgm_private value in the object is used, instead of the parent-level default.

The override_mgm_private attribute can be specified explicitly. It is also set implicitly when mgm_private is set to a defined value.

Note that setting override_mgm_private to 'false' sets the original 'mgm_private' value to 'false'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to 'true' to override the parent-level setting for mgm_private. Set the parameter to 'false' to inherit the parent-level setting for mgm_private.

The default value of this parameter is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get override_mgm_private value
my $value = $object->override_mgm_private( );

#Modify override_mgm_private value
$object->override_mgm_private('true');
```

override_subscribe_settings( )

The override_subscribe_settings attribute controls whether the subscribe_settings method values of the member are used, instead of the Grid default.

The override_subscribe_settings attribute can be specified explicitly. It is also set implicitly when subscribe_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for subscribe_settings. Set the parameter to "false" to inherit the Grid-level setting for subscribe_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_subscribe_settings value
my $override_subscribe_settings = $object->override_subscribe_settings( );
#Modify override_subscribe_settings value
$object->override_subscribe_settings("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the Grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    #Getting override_update_dns_on_lease_renewal
    my $override_update_dns_on_lease_renewal=$network_container-
>override_update_dns_on_lease_renewal( );
    #Modifying override_update_dns_on_lease_renewal
    $network_container->override_update_dns_on_lease_renewal("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the DHCP IPv6 Network Container is used, instead of the Grid default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for options. Set the parameter to "false" to inherit the Grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_valid_lifetime
my $override_valid_lifetime=$network_container->override_valid_lifetime( );
#Modifying override_valid_lifetime
$network_container->override_valid_lifetime("true");
```

preferred_lifetime ( )

Use this method to set or retrieve the preferred lifetime value of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_preferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(691200); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(691200); will result in override_preferred_lifetime="true".

Parameter

A 32-bit integer (valid range from 1 to 4294967295) that represents the lifetime, in seconds. The default value is 27000.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get Preferred lifetime
my $preferred_lifetime = $network_container->preferred_lifetime();
#Modify Prefered lifetime
$network_container->preferred_lifetime(864000);
```

port_control_blackout_setting

Use this method to set or retrieve the port control blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when port_control_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->port_control_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->port_control_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get port_control_blackout_setting
my $port_control_blackout_setting = $network->port_control_blackout_setting();
#Modify port_control_blackout_setting
$network->port_control_blackout_setting($blackout);
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag at the network container level.

If the flag is enabled, the leases are kept in the recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Setting this method to a defined value implicitly sets the override_recycle_leases method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_recycle_leases attribute to "false".

Note that when recycle_leases is set to a defined value and override_recycle_leases is set to "false", the last operation takes precedence.

Thus the sequence $object->recycle_leases("true"); $object->override_recycle_leases("false"); will set override_recycle_leases to "false", and the sequence $objct->override_recycle_leases("false"); $object->recycle_leases("true"); will result in override_recycle_leases="true".

Parameter

Specify "true" to enable the recycle_leases flag or "false" to disable it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $network_container->recycle_leases();
#Modify recycle_leases
$network_container->recycle_leases("false");
```

remove_subnets( )

Use this method to set or retrieve the remove_subnets flag of a DHCP IPv6 Network Container object.

You can set this flag to false, if you want to remove the network, but keep all subnets under it. This flag is used only when removing DHCP IPv6 Network Container objects. It is not retrieved or used for any other operation.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "false" to keep the subnets, or "true" to remove them. The default value is undefined, which is to remove all subnets.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Set remove_subnets before submitting for removal
$network_container->remove_subnets("false");
#Remove the container of the subnets
$session->remove($network_container);
```

restart_if_needed( )

Use this method to set the flag that indicates whether DHCP service should be restarted on a member that is serving DHCP for the changed object referenced in a cloud API request.

Parameter

Specify true to restart the DHCP service.

Returns

None

Example

```
# Modify
$network->restart_if_needed('true');
```

rir( )

Use this method to retrieve the name of the Regional Internet Registry (RIR) that allocated this address space. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'RIPE' or 'NONE'.

Example

```
#Get rir
my $rir = $network_container->rir();
```

rir_organization( )

Use this method to set or retrieve the Regional Internet Registry (RIR) organization object.

Parameter

An Infoblox::Grid::RIR::Organization object.

You must enable support for RIR/SWIP at the Grid level before you can set attribute values. See Infoblox::Grid->enable_rir_swip() method.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_organization
my $rir_organization = $network_container->rir_organization();
#Modify rir_organization
$network_container->rir_organization($rir_org);
```

rir_registration_action( )

Use this method to set the registration action of Regional Internet Registry (RIR). This is a write-only attribute.

Parameter

Valid values are 'NONE', 'CREATE', 'MODIFY' or 'DELETE'.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set rir_registration_action
$network_container->rir_registration_action('CREATE');
```

rir_registration_status( )

Use this method to set or retrieve the registration status of Regional Internet Registry (RIR).

Parameter

The registration status of Regional Internet Registry (RIR), which can be 'REGISTERED' or 'NOT_REGISTERED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_registration_status
my $rir_registration_status = $network_container->rir_registration_status();
#Modify rir_registration_status
$network_container->rir_registration_status('NOT_REGISTERED');
```

last_rir_registration_update_sent( )

Use this method to retrieve the last registration update timestamp of Regional Internet Registry (RIR). This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_rir_registration_update_sent
my $last_rir_registration_update_sent = $network_container->last_rir_registration_update_sent();
```

last_rir_registration_update_status( )

Use this method to retrieve the last registration update status of Regional Internet Registry (RIR). This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_rir_registration_update_status
my $last_rir_registration_update_status = $network_container->last_rir_registration_update_status();
```

same_port_control_discovery_blackout( )

Use this method to set or retrieve the flag that enables using the same discovery blackout for port control blackout.

Parameter

Specify 'true' to use same discovery blackout for port control blackout or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $network_container->same_port_control_discovery_blackout();
# Modify attribute value
$network_container->same_port_control_discovery_blackout('true');
```

send_rir_request( )

Use this method to set the flag that indicates whether the appliance should send an API or email request for Regional Internet Registry (RIR). This is a write-only attribute.

Parameter

Specify "true" to set the send_rir_request flag or "false" to unset it.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set send_rir_request
$network_container->send_rir_request('true');
```

subscribe_settings( )

Use this method to set or retrieve the Cisco ISE subscribe settings.

Setting this method to a defined value implicitly sets the override_subscribe_settings method to "true". Setting the parameter to undefined causes the appliance to use the Cisco ISE endpoint default and automatically resets the override_subscribe_settings method to "false".

Note that when subscribe_settings is set to a defined value and override_subscribe_settings is set to "false", the last operation takes precedence. Thus the sequence $object->subscribe_settings($value); $object->override_subscribe_settings("false"); will set override_subscribe_settings to "false", and the sequence $object->override_subscribe_settings("false"); $object->subscribe_settings($value); will result in override_subscribe_settings="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::CiscoISE::SubscribeSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscribe_settings value
my $subscribe_settings = $object->subscribe_settings();
#Modify subscribe_settings value
$object->subscribe_settings($settings);
```

delete_reason( )

Use this method to specify the reason for deleting the Regional Internet Registry (RIR) registration request. This is a write-only attribute. This field is required only if 'rir_registration_action' is specified as 'DELETE'

Parameter

The reason for deleting the RIR registration request in string format with a maximum of 256 bytes.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set delete_reason
$network_container->delete_reason('invalid');
```

unmanaged( )

Use this method to set or retrieve the network status, which indicates whether the network is unmanaged or not.

Parameter

Specify true to mark the network as unmanaged or false as managed.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get network status
$unmanaged = $network_container->unmanaged();
# Modify network status
$network_container->unmanaged('true');
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$network_container->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$network_container->update_dns_on_lease_renewal("true");
```

valid_lifetime ( )

Use this method to set or retrieve the valid lifetime value of a DHCP IPv6 Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_valid_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_valid_lifetime attribute to "false".

Note that when valid_lifetime is set to a defined value and override_valid_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->valid_lifetime(691200); $object->override_valid_lifetime("false"); will set override_valid_lifetime to "false", and the sequence $object->override_valid_lifetime("false"); $object->valid_lifetime(691200); will result in override_valid_lifetime="true".

Parameter

A 32-bit integer (valid range from 1 to 4294967295) that represents the valid lifetime, in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid lifetime
my $valid_lifetime = $network_container->valid_lifetime();
#Modify valid lifetime
$network_container->valid_lifetime(864000);
```

zone_associations( )

Use this method to set or retrieve the associated zone information.

Parameter

The valid value is an array reference that contains Infoblox::DNS::Zone object(s). The default value is an empty list. If the network container has a parent, it is possible to use the zone associations of the parent by setting the parameter to undef.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Examples

```
#Getting zone associations
my $zone_associations = $network_container->zone_associations();
my $zone1 = Infoblox::DNS::Zone->new(
      name     => "test1.com",
);
my $zone2 = Infoblox::DNS::Zone->new(
      name     => "test2.com",
   );
#Modifying zone_associations
$network_container->zone_associations([$zone1, $zone2]);
#Clear zone_associations
$network_container->zone_associations([]);
##Remove the override for zone_associations
$network_container->zone_associations(undef)
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP IPv6 Network Container object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
```

```
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP IPv6 Network Container object

```
my $network_container = Infoblox::DHCP::IPv6NetworkContainer->new(
            network => "2001::/64",
            comment => "add network container",
             );

my $response = $session->add($network_container)
       or die("Add Network Container failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Network Container added successfully\n";

#Search for a specific Network Container

#Search the network container
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::IPv6NetworkContainer",
    network => "2001.*"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search Network Container failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search Network Container found at least 1 matching entry\n";
```

#Get and modify an IPv6 Network Container attribute

```
#Get Network Container through the session
my @retrieved_objs = $session->get(
           object =>"Infoblox::DHCP::IPv6NetworkContainer" ,
           network => "2001::/64"
        );

my $object = $retrieved_objs[0];

unless ($object) {
    die("Get Network Container object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Network Container found at least 1 matching entry\n";
```

#Modify one of the attributes of the specified IPv6 network container attribute

```
$object->comment("modified comment"); #Apply the changes

$session->modify($object)
    or die("Modify Network Container attribute failed: ",
           $session->status_code() . ":" . $session->status_detail());

print "Network Container object modified successfully \n";
```

#Remove a Network Container Object

```
 #Get Network Container object through the session
 my @retrieved_objs = $session->get(
           object  => "Infoblox::DHCP::IPv6NetworkContainer" ,
           network => "2001::"
       );
```

```
    my $object = $retrieved_objs[0];

    unless ($object) {
     die("Get Network Container object failed: ",
         $session->status_code() . ":" . $session->status_detail());
     }

 print "Get Network Container object found at least 1 matching entry\n";
```

#Submit the object for removal

```
 $session->remove($object)
     or die("Remove Network Container failed: ",
         $session->status_code() . ":" . $session->status_detail());

 print "Network Container removed successfully \n";
```

NAME

Infoblox::DHCP::IPv6NetworkTemplate - DHCP IPv6 Network Template object

---

DESCRIPTION

You can use a template to create IPv6 networks in a quick and consistent way. Networks created from a network template inherit all the properties defined in the network template, except for the comment and cidr if they are defined in the network.

CONSTRUCTOR

```
my $ipv6network_template = Infoblox::DHCP::IPv6NetworkTemplate->new(
```

```
        name                                => $string,
#Required
        allow_any_netmask                   => "true" | "false",
#Optional / Default is "false"
        auto_create_reversezone             => "true" | "false",
#Optional / Default is "false"
        cidr                                => $num,
#Optional / Default is undefined
        comment                             => $string,
#Optional / Default is empty
        ddns_domainname                     => $fqdn,
#Optional / Default is undefined
        ddns_enable_option_fqdn             => "true" | "false" ,
#Optional / Default is "false"
        ddns_generate_hostname              => "true" | "false" | undef,
#Optional / Default is undefined
        ddns_server_always_updates          => "true" | "false",
#Optional / Default is "true"
        ddns_ttl                            => $num,
#Optional / Default is 0
        domain_name                         => $fqdn,
#Optional / Default is undefined
        domain_name_servers                 => "$ipv6addr1,$ipv6addr2,...",
#Optional / Default is undefined
        enable_ddns                         => "true" | "false" | undef,
#Optional / Default is undefined
        extattrs                            => { $string => $extattr, ... },
#Required if 'rir_organization' attribute is defined

#Otherwise is optional
        extensible_attributes               => { $string => $string | $num, $string => [ $string |
$num, ... ], ... },

#Required if 'rir_organization' attribute is defined

#Otherwise is optional

        fixed_address_templates             => [$DhcpTemplate1,$DhcpTemplate2,...],
#Optional / Default is empty
        ipv6prefix                          => $ipv6prefix,
#Optional / Default is undefined
        members                             => [$Member1, $Member2, ...],
#Optional / Default is empty
        options                             => [$Option1, $Option2, ...],
#Optional / Default is empty list
        override_ddns_domainname            => "true" | "false",
#Optional / Default is "false"
        override_ddns_enable_option_fqdn    => "true" | "false",
#Optional / Default is "false"
        override_ddns_generate_hostname     => "true" | "false",
#Optional / Default is "false"
        override_ddns_ttl                   => "true" | "false",
#Optional / Default is "false"
        override_domain_name                => "true" | "false",
#Optional / Default is "false"
        override_domain_name_servers        => "true" | "false",
#Optional / Default is "false"
        override_enable_ddns                => "true" | "false",
#Optional / Default is "false"
        override_options                    => "true" | "false",
#Optional / Default is "false"
        override_preferred_lifetime         => "true" | "false",
#Optional / Default is "false"
        override_recycle_leases             => "true" | "false",
#Optional / Default is "false"
        override_update_dns_on_lease_renewal => "true" | "false",
#Optional / Default is "false"
        override_valid_lifetime             => "true" | "false",
#Optional / Default is "false"
        preferred_lifetime                  => $num,
#Optional / Default is 27000
        range_templates                     => [$RangeTemplate1,$RangeTemplate2,...],
#Optional / Default is empty
        recycle_leases                      => "true" | "false" | undef,
#Optional / Default is undefined
        rir_organization                    => $rir_org,
#Optional / An Infoblox::Grid::RIR::Organization object
        rir_registration_action             => 'NONE' | 'CREATE',
#Optional / Default is 'NONE'
        rir_registration_status             => 'NOT_REGISTERED' | 'REGISTERED',
#Optional / Default is 'NOT_REGISTERED'
        send_rir_request                    => 'true' | 'false',
#Optional / Default is 'false'
        update_dns_on_lease_renewal         => "true" | "false",
#Optional / Default is "false"
```

```
        valid_lifetime                          => $num,
#Optional / Default is 43200
        );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a DHCP IPv6 network template object.

Infoblox::Session->add( )

Use this method to add an IPv6 network template object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $ipv6network_template = Infoblox::DHCP::IPv6NetworkTemplate->new(
       name               => "custom_network_template",
       allow_any_netmask => "true",
);

# Submit for addition
my $response = $session->add( $ipv6network_template );
```

Infoblox::Session->get( )

Use this method to retrieve the matching IPv6 network template objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 network template object:

 name - Required. The name of network template.
 extattrs     - Optional. A hash reference containing extensible attributes.
```

Example

```
 my  @result_array = $session->get(
      object  => "Infoblox::DHCP::IPv6NetworkTemplate" ,
      name    => "custom_network_template"
 );
```

Infoblox::Session->search( )

Use this method to retrieve all the matching IPv6 network template objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific DHCP IPv6 network template object:

 name     - Optional. The name of the network template (regular
            expression).
 comment - Optional. The comment of the network template (regular
            expression).
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
 my  @result_array = $session->search(
      object  => "Infoblox::DHCP::IPv6NetworkTemplate" ,
      name    => "custom_network_template"
  comment => ".*",
 );

 # search all Network Templates with a given extensible attribute 'Site'
 my @retrieved_objs = $session->search(
   object => "Infoblox::DHCP::IPv6NetworkTemplate",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify an IPv6 network template in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Modify enable_ddns method
$object->enable_ddns("true");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve it, and then submit it for removal.

Example

```
# Get the object under the same name
my  @result_array = $session->get(

      object => "Infoblox::DHCP::IPv6NetworkTemplate" ,
      name   => "custom_network_template"
            );

# Find the desired object in the retrieved list
my $desired_network_template = $result_array[0];

# Submit for removal
my $response = $session->remove( $desired_network_template );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP IPv6 network template object.

allow_any_netmask( )

Use this method to set or retrieve the allow_any_netmask parameter of a DHCP IPv6 network template object. If you set this parameter to "true", then the template allows any netmask. A user must specify a netmask when creating a network using this template. If you set this parameter to false, you must specify the "netmask" property for the network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the allow_any_netmask parameter or specify "false" if you want to specify a particular netmask. The default value is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get allow_any_netmask
my $allow_any_netmask = $ipv6network_template->allow_any_netmask()
# Modify allow_any_netmask
$ipv6network_template->allow_any_netmask("true");
```

auto_create_reversezone( )

Use this method to set or retrieve the auto_create_reversezone flag of a DHCP IPv6 network template object. This flag indicates whether the appliance must automatically create the corresponding reverse zone.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to create a reverse zone automatically or "false" to disable the automatic creation of a reverse zone.The default value for this field is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get auto_create_reversezone
my $auto_create_reversezone = $ipv6network_template->auto_create_reversezone();
# Modify auto_create_reversezone
$ipv6network_template->auto_create_reversezone("true");
```

cidr( )

Use this method to set or retrieve the CIDR for the IPv6 network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the CIDR as a number from 1 to 128.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get CIDR
my $cidr = $ipv6network_template->cidr();
#Modify CIDR
$ipv6network_template->cidr("68");
```

comment( )

Use this method to set or retrieve a descriptive comment about a DHCP IPv6 network template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network template in string format and with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $ipv6network_template->comment();
# Modify comment
$ipv6network_template->comment("add a network");
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP IPv6 Network Tempate object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_ddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $ipv6network_template->ddns_domainname();
#Modify ddns_domainname
$ipv6network_template->ddns_domainname("test_domain.com");
```

ddns_enable_option_fqdn( )

Use this method to set or retrieve the ddns_enable_option_fqdn flag of a DHCP IPv6 network template object. This method controls whether the FQDN option sent by the client is to be used, or if the server can automatically generate the FQDN. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_enable_option_fqdn method to "true". Setting the parameter to undefined causes the appliance to use the upper-level setting and automatically resets the override_ddns_enable_option_fqdn attribute to "false".

Note that when ddns_enable_option_fqdn is set to a defined value and override_ddns_enable_option_fqdn is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_enable_option_fqdn("true"); $object->override_ddns_enable_option_fqdn("false"); will set override_ddns_enable_option_fqdn to "false", and the sequence $object->override_ddns_enable_option_fqdn("false"); $object->ddns_enable_option_fqdn("true"); will result in override_ddns_enable_option_fqdn="true".

Parameter

Specify "true" to generate the hostname or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_enable_option_fqdn
my $ddns_enable_option_fqdn = $ipv6network_template->ddns_enable_option_fqdn()
# Modify ddns_enable_option_fqdn
$ipv6network_template->ddns_enable_option_fqdn("true");
#Remove override
$network_template->ddns_enable_option_fqdn(undef);
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a DHCP IPv6 network template object. Set this flag to allow only the DHCP server to generate a hostname. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_generate_hostname method to "true". Setting the parameter to undefined causes the appliance to use the upper-level setting and automatically resets the override_ddns_generate_hostname attribute to "false".

Note that when ddns_generate_hostname is set to a defined value and override_ddns_generate_hostname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_generate_hostname("true"); $object->override_ddns_generate_hostname("false"); will set override_ddns_generate_hostname to "false", and the sequence $object->override_ddns_generate_hostname("false"); $object->ddns_generate_hostname("true"); will result in override_ddns_generate_hostname="true".

Parameter

Specify "true" to generate the hostname or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_generate_hostname
```

```
my $ddns_generate_hostname = $ipv6network_template->ddns_generate_hostname()
# Modify ddns_generate_hostname
$ipv6network_template->ddns_generate_hostname("true");
#Remove override
$network_template->ddns_generate_hostname(undef);
```

ddns_server_always_updates( )

Use this method to set or retrieve the ddns_server_always_updates flag of a DHCP IPv6 network template object. Set this flag to allow the DHCP server only to update DNS, regardless of the requests from DHCP clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set this flag and allow only the DHCP server to update DNS or "false" to deactivate/unset the flag. The default value is true.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_server_always_updates
my $ddns_server_always_updates = $ipv6network_template->ddns_server_always_updates()
# Modify ddns_server_always_updates
$ipv6network_template->ddns_server_always_updates("true");
```

ddns_ttl( )

Use this method to set or retrieve the DNS update Time to Live (TTL) value of a DHCP IPv6 network template object. The TTL value indicates the number of seconds the Infoblox appliance caches a DDNS update.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_dddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer, from 0 to 4294967295, that represents the duration, in seconds, that the update is cached. Zero indicates that the update will not be cached. The default value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get DNS Update TTL
my $dns_ttl = $ipv6network_template->ddns_ttl();
#Modify DNS Update TTL
$ipv6network_template->ddns_ttl(1200);
```

domain_name( )

Use this method to set or retrieve the domain_name value of a DHCP IPv6 network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_domain_name attribute to "false".

Note that when domain_name is set to a defined value and override_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name("testdomain"); $object->override_domain_name("false"); will set override_domain_name to "false", and the sequence $object->override_domain_name("false"); $object->domain_name("testdomain"); will result in override_domain_name="true".

Parameter

The client's domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name
my $domain_name = $ipv6network_template->domain_name();
#Modify domain_name
$ipv6network_template->domain_name("test_domain.com");
```

domain_name_servers( )

Use this method to set or retrieve the domain_name_servers value of a DHCP IPv6 network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_domain_name_servers attribute to "false".

Note that when domain_name_servers is set to a defined value and override_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name_servers("2001::1,2001::2"); $object->override_domain_name_servers("false"); will set override_domain_name_servers to "false", and the sequence $object->override_domain_name_servers("false"); $object->domain_name_servers("2001::1,2001::2"); will result in override_domain_name_servers="true".

Parameter

The domain name server addresses in IPv6 address format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name_servers
my $domain_name_servers = $ipv6network_template->domain_name_servers();
#Modify domain_name_servers
$ipv6network_template->domain_name_servers("2001::1,2001::2");
```

enable_ddns( )

Use this method to set or retrieve the dynamic DNS updates flag of a DHCP IPv6 network template object. The DHCP server can send DDNS updates to DNS servers in the same grid and to external DNS servers. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_ddns method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_enable_ddns attribute to "false".

Note that when enable_ddns is set to a defined value and override_enable_ddns is set to "false", the last operation takes precedence. Thus the sequence $object->enable_ddns("true"); $object->override_enable_ddns("false"); will set override_enable_ddns to "false", and the sequence $object->override_enable_ddns("false"); $object->enable_ddns("true"); will result in override_enable_ddns="true".

Parameter

Specify "true" to set the dynamic DNS updates flag or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ddns
my $enable_ddns = $ipv6network_template->enable_ddns()
# Modify enable_ddns
$ipv6network_template->enable_ddns("true");
# Remove the enable_ddns override
```

```
$ipv6network_template->enable_ddns(undef);
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with an IPv6 network template object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $ipv6network_template->extattrs();
#Modify extattrs
$ipv6network_template->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with an IPv6 network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $ipv6network_template->extensible_attributes();
#Modify extensible attributes
$ipv6network_template->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [
'Peter', 'Tom' ] });
```

fixed_address_templates( )

Use this method to set or retrieve the IPv6 fixed address template that is assigned to this IPv6 network template. When you create a network based on a network template that includes a fixed address template, the fixed addresses are created based on the associated fixed address template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference of Infoblox::DHCP::Template objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get fixed_address_templates
my $fixed_address_templates = $ipv6network_template->fixed_address_templates();
# Modify fixed_address_templates
my $tmpl = Infoblox::DHCP::Template->new(
   name => "custom_fixed_address_template"
);
$network_template->fixed_address_templates([$tmpl]);
```

ipv6prefix( )

Use this method to set or retrieve the IPv6 prefix of a DHCP IPv6 network template object. The prefix must belong to the list of global prefixes defined in the Infoblox::Grid::DHCP object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IPv6 prefix from the list of global IPv6 prefixes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. ls.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6prefix
my $ipv6prefix = $ipv6network_template->ipv6prefix();
#Modify ipv6prefix
$griddhcp->ipv6prefix("2001::");
```

members( )

Use this method to set or retrieve the member assigned to the IPv6 network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Member objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $member1 = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
);

#Create a network template with this member
my $ipv6network_template = Infoblox::DHCP::IPv6NetworkTemplate->new(
    name    => "custom_network_template",
    members => [$member1],
);
```

name( )

Use this method to set or retrieve the name of the DHCP IPv6 network template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The network template name in string format and with a maximum of 64 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $ipv6network_template->name();
#Modify name
$ipv6network_template->name("custom_network_template");
```

options( )

Use this method to set or retrieve the options value of an IPv6 network template object. DHCP options provide network configuration

settings and various services available on the network for DHCP. This setting overrides the upper-level setting. The default value is undefined which indicates that this attribute inherit the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_options method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_options attribute to "false".

Note that when the options method is set to a defined value and override_options is set to "false", the last operation takes precedence. Thus the sequence $object->options([$opt]); $object->override_options("false"); will set override_options to "false", and the sequence $object->override_options("false"); $object->options([$opt]); will result in override_options="true".

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $ipv6network_template->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name   => "dhcp6.rapid-commit",
    value  => "true"
);
$ipv6network_template->options([$option1]);
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP IPv6 Network Template is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$ipv6network_template->override_ddns_domainname( );
#Modifying override_ddns_domainname
$ipv6network_template->override_ddns_domainname("true");
```

override_ddns_enable_option_fqdn( )

The override_ddns_enable_option_fqdn attribute controls whether the ddns_enable_option_fqdn value in the DHCP IPv6 network template is used, instead of the grid default.

The override_ddns_enable_option_fqdn attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_enable_option_fqdn. Set the parameter to "false" to inherit the grid-level setting for ddns_enable_option_fqdn.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ddns_enable_option_fqdn
my $override_ddns_enable_option_fqdn=$ipv6network_template->override_ddns_enable_option_fqdn( );
#Modify override_ddns_enable_option_fqdn
$ipv6network_template->override_ddns_enable_option_fqdn("true");
```

override_ddns_generate_hostname( )

The override_ddns_generate_hostname attribute controls whether the ddns_generate_hostname value in the DHCP IPv6 network template is used, instead of the grid default.

The override_ddns_generate_hostname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_generate_hostname. Set the parameter to "false" to inherit the grid-level setting for ddns_generate_hostname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ddns_generate_hostname
my $override_ddns_generate_hostname=$ipv6network_template->override_ddns_generate_hostname( );
#Modify override_ddns_generate_hostname
$ipv6network_template->override_ddns_generate_hostname("true");
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the DHCP IPv6 network template object is used, instead of the grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_ttl. Set the parameter to "false" to inherit the grid-level setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ddns_ttl
my $override_ddns_ttl=$ipv6network_template->override_ddns_ttl( );
#Modify override_ddns_ttl
$ipv6network_template->override_ddns_ttl("true");
```

override_domain_name( )

The override_domain_name attribute controls whether the domain_name value in the DHCP IPv6 network template is used, instead of the grid default.

The override_domain_name attribute can be specified explicitly. It is also set implicitly when domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for domain_name. Set the parameter to "false" to inherit the grid-level setting for domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_domain_name
my $override_domain_name=$ipv6network_template->override_domain_name( );
#Modifying override_domain_name
$ipv6network_template->override_domain_name("true");
```

override_domain_name_servers( )

The override_domain_name_servers attribute controls whether the domain_name_servers value in the DHCP IPv6 network template is used, instead of the grid default.

The override_domain_name_servers attribute can be specified explicitly. It is also set implicitly when domain_name_servers is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for domain_name_servers. Set the parameter to "false" to inherit the grid-level setting for domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_domain_name_servers
my $override_domain_name_servers=$ipv6network_template->override_domain_name_servers( );
#Modify override_domain_name_servers
$ipv6network_template->override_domain_name_servers("true");
```

override_enable_ddns( )

The override_enable_ddns attribute controls whether the enable_ddns value in the DHCP IPv6 network template is used, instead of the grid default.

The override_enable_ddns attribute can be specified explicitly. It is also set implicitly when enable_ddns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ddns. Set the parameter to "false" to inherit the grid-level setting for enable_ddns.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_enable_ddns
```

```
my $override_enable_ddns=$ipv6network_template->override_enable_ddns( );
#Modify override_enable_ddns
$ipv6network_template->override_enable_ddns("true");
```

override_options( )

The override_options attribute controls whether the options in the DHCP IPv6 network template are used, instead of the grid default.

The override_options attribute can be specified explicitly. It is also set implicitly when options is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_options
my $override_options=$ipv6network_template->override_options( );
#Modify override_options
$ipv6network_template->override_options("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP IPv6 network template is used, instead of the grid default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_preferred_lifetime
my $override_preferred_lifetime=$ipv6network_template->override_preferred_lifetime( );
#Modify override_preferred_lifetime
$ipv6network_template->override_preferred_lifetime("true");
```

override_recycle_leases( )

The override_recycle_leases attribute controls whether the recycle_leases value in the DHCP IPv6 network template is used, instead of the grid default.

The override_recycle_leases attribute can be specified explicitly. It is also set implicitly when recycle_leases is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_recycle_leases
my $override_recycle_leases=$ipv6network_template->override_recycle_leases( );
#Modify override_recycle_leases
$ipv6network_template->override_recycle_leases("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP IPv6 network template is used, instead of the grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_update_dns_on_lease_renewal
my $override_update_dns_on_lease_renewal=$ipv6network_template-
>override_update_dns_on_lease_renewal( );
#Modify override_update_dns_on_lease_renewal
$ipv6network_template->override_update_dns_on_lease_renewal("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the DHCP IPv6 network template object is used, instead of the upper-level default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_valid_lifetime
my $override_valid_lifetime=$ipv6network_template->override_valid_lifetime( );
#Modify override_valid_lifetime
$ipv6network_template->override_valid_lifetime("true");
```

preferred_lifetime( )

Use this method to set or retrieve the valid lifetime of the DHCP IPv6 network template object.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined

causes the appliance to use the upper-level default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_preferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(20000); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(20000); will result in override_preferred_lifetime="true".

Parameter

Preferred lifetime value in seconds. The default value is 27000. Note that the preferred lifetime cannot be greater than the valid lifetime.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get preferred_lifetime
my $preferred_lifetime = $ipv6network_template->preferred_lifetime();
#Modify preferred_lifetime
$ipv6network_template->preferred_lifetime(12345);
```

range_templates( )

Use this method to set or retrieve the IPv6 address range template assigned to this IPv6 network template object. When you create a network based on a network template object with a range template, the IPv6 address ranges are created based on the associated IPv6 address range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference of Infoblox::DHCP::Template objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_templates
my $range_templates = $ipv6network_template->range_templates();
#Modify range_templates
my $tmpl = Infoblox::DHCP::Template->new(
   name => "custom_range_template"
);
$ipv6network_template->range_templates([ $tmpl ]);
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag for an IPv6 network template object.

If the flag is enabled, the leases are kept in the recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Setting this method to a defined value implicitly sets the override_recycle_leases method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_recycle_leases attribute to "false".

Note that when recycle_leases is set to a defined value and override_recycle_leases is set to "false", the last operation takes precedence. Thus the sequence $object->recycle_leases("true"); $object->override_recycle_leases("false"); will set override_recycle_leases to "false", and the sequence $objct->override_recycle_leases("false"); $object->recycle_leases("true"); will result in override_recycle_leases="true".

Parameter

Specify "true" to enable the recycle_leases flag or "false" to disable it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $ipv6network_template->recycle_leases();
#Modify recycle_leases
$ipv6network_template->recycle_leases("false");
```

rir( )

Use this method to retrieve the name of the Regional Internet Registry (RIR) that allocated this address space. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'RIPE' or 'NONE'.

Example

```
#Get rir
my $rir = $ipv6network_template->rir();
```

rir_organization( )

Use this method to set or retrieve the Regional Internet Registry (RIR) organization object.

Parameter

An Infoblox::Grid::RIR::Organization object.

You must enable support for RIR/SWIP at the Grid level before you can set attribute values. See Infoblox::Grid->enable_rir_swip() method.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_organization
my $rir_organization = $ipv6network_template->rir_organization();
#Modify rir_organization
$ipv6network_template->rir_organization($rir_org);
```

rir_registration_action( )

Use this method to set or retrieve the registration action of Regional Internet Registry (RIR).

Parameter

Valid values are 'NONE', 'CREATE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_registration_action
my $rir_registration_action = $ipv6network_template->rir_registration_action();
#Modify rir_registration_action
$ipv6network_template->rir_registration_action('CREATE');
```

rir_registration_status( )

Use this method to set or retrieve the registration status of Regional Internet Registry (RIR).

Parameter

The registration status of Regional Internet Registry (RIR), which can be 'REGISTERED' or 'NOT_REGISTERED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_registration_status
my $rir_registration_status = $ipv6network_template->rir_registration_status();
#Modify rir_registration_status
$ipv6network_template->rir_registration_status('NOT_REGISTERED');
```

send_rir_request( )

Use this method to set or retrieve the flag that indicates whether the appliance should send an API or email request for Regional Internet Registry (RIR).

Parameter

Specify "true" to set the send_rir_request flag or "false" to unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get send_rir_request
my $send_rir_request = $ipv6network_template->send_rir_request();
#Modify send_rir_request
$ipv6network_template->send_rir_request('true');
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$ipv6network_template->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$ipv6network_template->update_dns_on_lease_renewal("true");
```

valid_lifetime( )

Use this method to set or retrieve the valid lifetime of the DHCP IPv6 network template object.

Setting this method to a defined value implicitly sets the override_valid_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_valid_lifetime attribute to "false".

Note that when valid_lifetime is set to a defined value and override_valid_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->valid_lifetime(20000); $object->override_valid_lifetime("false"); will set override_valid_lifetime to "false", and the sequence $object->override_valid_lifetime("false"); $object->valid_lifetime(20000); will result in override_valid_lifetime="true".

Parameter

Valid lifetime value in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid_lifetime
my $valid_lifetime = $ipv6network_template->valid_lifetime();
#Modify valid_lifetime
$ipv6network_template->valid_lifetime(12345);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

```
#Preparation prior to a DHCP IPv6 network template object insertion
```

#PROGRAM STARTS: Include all the modules that will be used use strict; use Infoblox; **#Create a session to the Infoblox DNSone appliance** my $session = Infoblox::Session->new(master => "192.168.1.2", username => "admin", password => "infoblox");

```
unless ($session) {
    die("Construct session failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $memberdhcp = Infoblox::DHCP::Member->new(
    name     => $host_name,
    ipv4addr => $node_ip
);
```

#Add IPv6 network template object

```
#Create a DHCP network template object

my $network_template = Infoblox::DHCP::IPv6NetworkTemplate->new(
    name                   => "custom_network_template",
    cidr                   => 64,
    comment                => "add IPv6 network template",
    members                => [ $memberdhcp ],
    enable_ddns            => "false",
    valid_lifetime         => 99999,
    auto_create_reversezone => "true",
);

my $response = $session->add($network_template)
    or die("Add Network template failed: ",
    $session->status_code() . ":" . $session->status_detail());

print "Network template added successfully\n";
```

#Get and modify an IPv6 network template attribute

```
#Get Network template through the session
my  @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6NetworkTemplate",
    name   => "custom_network_template"
);

my $object = $retrieved_objs[0];

unless ($object) {
    die("Get Network template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Network template found at least 1 matching entry\n";
```

#Search an IPv6 network template attribute

```
#Search Network template through the session
```

```
my  @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::IPv6NetworkTemplate",
    name   => "custom_network_template"
);

my $object = $retrieved_objs[0];

unless ($object) {
    die("Search Network template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search Network template found at least 1 matching entry\n";

#Modify attributes of the specified IPv6 network template

$object->enable_ddns("true"); #Apply the changes

$session->modify($object)
    or die("Modify Network template attribute failed: ",
    $session->status_code() . ":" . $session->status_detail());

print "Network template object modified successfully \n";
```

#Remove an IPv6 network template object

```
#Get IPv6 Network Template object through the session

my @retrieved_objs = $session->get(
    object  => "Infoblox::DHCP::IPv6NetworkTemplate",
    name    => "custom_network_template"
);

my $object = $retrieved_objs[0];

unless ($object) {
    die("Get IPv6 Network Template object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Get IPv6 Network Template object found at least 1 matching entry\n";

#Submit the object for removal

$session->remove($object)
    or die("Remove IPv6 Network Template failed: ",
    $session->status_code() . ":" . $session->status_detail());

print "IPv6 Network Template removed successfully \n";

NAME

Infoblox::DHCP::IPv6OptionDefinition - DHCP IPv6 option definition object

---

DESCRIPTION

An IPv6OptionDefinition defines an IPv6 DHCP option within a specific IPv6 option space. A custom option can be defined in the predefined DHCP option space or in the user-defined vendor option space. To define an option, add the option definition to the required option space.

CONSTRUCTOR

```
my $ipv6od = Infoblox::DHCP::IPv6OptionDefinition->new(
                name  => $string, #Required
                code  => $num,    #Required
                space => $string, #Optional / Default is DHCP
                type  => $string, #Optional / Default is string
             );
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that can be applied to a DHCP IPv6 option definition object.

Infoblox::Session->add( )

Use this method to add an IPv6 option definition object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Create a DHCP IPv6OptionDefinition object.
my $ipv6od = Infoblox::DHCP::IPv6OptionDefinition->new(
                space => "SUNW",
                name  => "JumpStart-server",
                code  => "6",
                type  => "text"
             );
# Submit for adding
my $response = $session->add( $ipv6od );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching DHCP IPv6 option definition objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 option definition object:

 name  - A name for the option definition in string format (regular expression).
```

```
  code  - Option number. Either a name or code is required.
  space - Optional. The option space in which the option is defined. The default is the "DHCPv6"
option space.
```

Example

```
#Getting option by name
my  @result_array = $session->get(
                        object   => "Infoblox::DHCP::IPv6OptionDefinition",
                        space    => "SUNW",
                        name     => "JumpStart-server",
                        );

#Getting option by code
my @result_array = $session->get(
                        object   => "Infoblox::DHCP::IPv6OptionDefinition",
                        space    => "DHCPv6",
                        code     => 176,
                        );
```

Infoblox::Session->modify( )

Use this method to modify a DHCP IPv6 option definition object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify code
$object->code(20);
# Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->search( )

Use this method to retrieve all the matching DHCP IPv6 option definition objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 option definition object:

  name  - A name for the option definition in string format (regular expression).
  code  - Option number. Either a name or code is required.
  space - Optional. The option space in which the option is defined. The default is the "DHCPv6"
option space.
```

Example

```
#Getting option by name
my  @result_array = $session->search(
                        object   => "Infoblox::DHCP::IPv6OptionDefinition",
                        space    => "SUNW",
                        name     => "JumpStart-server",
                        );

#Getting option by code
my @result_array = $session->search(
                        object   => "Infoblox::DHCP::IPv6OptionDefinition",
                        space    => "DHCPv6",
                        code     => 176,
                        );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP IPv6 option definition object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` to retrieve the specific object, and then submit this object for removal.

Example

```
my  @result_array = $session->get(
                        object   => "Infoblox::DHCP::IPv6OptionDefinition",
                        space    => "SUNW",
                        name     => "JumpStart-server",
                        );

# find the desired object from retrieved list.
```

```
my $desired_obj = $result_array[0];

# Submit for removal
my $response = $session->remove($desired_obj);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP IPv6 option definition object.

name( )

Use this method to set or retrieve the name of a DHCP IPv6 option definition object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get name
my $od_name = $ipv6od->name();
# Modify name
$ipv6od->name("Start-server");
```

code( )

Use this method to set or retrieve the code of a DHCP IPv6 option definition object. An option code number is used to identify the DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number for the option code. Value must be between 1 and 254. Values 2, 7, 12, 14, 21-14, 27-34, and 39 are predefined. These option codes have corresponding predefined Types. Therefore, you cannot change the predefined Types.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get code
my $od_code = $ipv6od->code();
# Modify code
$ipv6od->code(14);
```

space( )

Use this method to set or retrieve the space of a DHCP IPv6 option definition object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the space name in string format.

Returns

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get space
my $od_space = $ipv6od->space();
# Modify space
$ipv6od->space("SUNW");
```

type( )

Use this method to set or retrieve the data type of the grid DHCP IPv6 option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The accepted types are the following:

```
  "boolean"                 - For "true" or "false" boolean values.

  "ip-address"              - For a single IPv6 address. An IPv6 address is a 128-bit number.
                              It consist of eight groups of hexadecimal digits separated
                              by colon (example: "2001:1dfc:2dfb:0:c1:0:a0:a2"). A group of all zeros
                              can be replaced by a double colon (e.g. 2001:1dfc:2dfb::1 is equivalent
                              to 2001:1dfc:2dfb:0:0:0:0:1).

  "array of ip-address"     - For a list of IPv6 addresses, each separated by a comma.
                              (example: "2002:d0:d2::1, 2002:d0:d2::3, 2001::3")

  "string"                  - For value in ASCII text string or
                              a list of hexadecimal characters (0-9, a-f, or A-F) without spaces and
separated by colons.

  "text"                    - For value in ASCII text string.

  "domain-name"             - For domain name in ASCII text format

  "domain-list"             - For a list of domain names, each separated by a comma.

  "8-bit unsigned integer"  - For numeric value between 0 and 255.

  "16-bit unsigned integer" - For numeric value between 0 and 65535.

  "32-bit unsigned integer" - For numeric value between 0 and 4294967295.

  "8-bit signed integer"    - For numeric value between -128 and 127.

  "16-bit signed integer"   - For numeric value between -32768 and 32767.

  "32-bit signed integer"   - For numeric value between -2147483648 and 2147483647.

  "array of 8-bit unsigned integer"  - For a list of numeric values between 0 and 255, each separated
by a comma.

  "array of 16-bit unsigned integer" - For a list of numeric values between 0 and 65535, each
separated by a comma.

  "array of 32-bit unsigned integer" - For a list of numeric values between 0 and 4294967295, each
separated by a comma.

  "array of 8-bit integer"           - For a list of numeric values between -128 and 127, each
separated by a comma.

  "array of 16-bit integer"          - For a list of numeric values between -32768 and 32767, each
separated by a comma.

  "array of 32-bit integer"          - For a list of numeric values between -2147483648 and
2147483647, each separated by a comma.
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get type
my $od_type = $ipv6od->type();
# Modify type
$ipv6od->type("string");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP Network insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
```

```
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $ipv6od = Infoblox::DHCP::IPv6OptionSpace->new("name" => "SUNW");
my $response = $session->add($ipv6od);
print "Add option space operation success \n" if ($response);
print "Add option space operation failed  \n" if (not $response);
```

#Create a DHCP IPv6 OptionDefinition object.

```
my $ipv6od = Infoblox::DHCP::OptionDefinition->new(
                                space => "SUNW",
                                name  => "JumpStart-server",
                                code  => "6",
                                type  => "text"
                              );
unless ($ipv6od) {
    die("Construct DHCP IPv6OptionDefinition failed: ",
    Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP IPv6OptionDefinition object created successfully\n";

#Add the DHCP IPv6OptionDefinition object to Infoblox appliance through a session
my $response = $session->add( $ipv6od )
   or die("Add a DHCP IPv6OptionDefinition object failed: ",
          $session->status_code() . ":" . $session->status_detail());

print "Add a DHCP IPv6OptionDefinition object successfully\n";
```

#Get and modify a DHCP OptionDefinition object attribute

```
#Get Network through the session
my @retrieved_objs = $session->get(
               object   => "Infoblox::DHCP::IPv6OptionDefinition",
               space  => "SUNW",
               name   => "JumpStart-server",
            );

my $object = $retrieved_objs[0];

unless ($object) {
    die("Get DHCP IPv6OptionDefinition object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get DHCP IPv6OptionDefinition object found at least 1 matching entry\n";

#Modify one of the attributes of the specified Network attribute

$object->code(20);    #Apply the changes

$session->modify($object)
    or die("Modify DHCP IPv6OptionDefinition attribute failed: ",
           $session->status_code() . ":" . $session->status_detail());

print "DHCP IPv6OptionDefinition object modified successfully \n";
```

#Remove a DHCP IPv6OptionDefinition Object

```
#Get DHCP IPv6OptionDefinition object through the session
my @retrieved_objs = $session->get(
               object =>"Infoblox::DHCP::IPv6OptionDefinition",
               space  => "SUNW",
               name   => "JumpStart-server",
            );
```

```
my $object = $retrieved_objs[0];

NAME

Infoblox::DHCP::IPv6OptionSpace - DHCP IPv6 OptionSpace object.

DESCRIPTION

An Option Space defines a namespace in which vendor options can be defined. This object is for an IPv6 option space. To define a specific vendor option space, add an option space to DHCP.

CONSTRUCTOR

```
my $ipv6os = Infoblox::DHCP::IPv6OptionSpace->new(
      name              => $string, #Required
      enterprise_number  => $num,    #Required, if this is a vendor option space.  It is optional
otherwise.
      comment           => $string, #Optional, default is undefined
);
```

SESSION METHODS

This section describes all the methods in Infoblox::Session module that can be applied to a DHCP IPv6 OptionSpace object.

Infoblox::Session->add( )

Use this method to add a DHCP IPv6 OptionSpace object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct a DHCP IPV6 OptionSpace object
my $ipv6os = Infoblox::DHCP::IPv6OptionSpace->new(
      name => "infospace",
      comment => "some comment",
      enterprise_number => 123,
);
#Submit for addition
my $response = $session->add($ipv6os)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 OptionSpace object:

 name     - Required. Option space name in string format.
 comment  - Optional. Option space comment.
 enterprise_number - Optional. Enterprise number.
```

Example

```
#Get DHCP IPv6 OptionSpace object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6OptionSpace",
    name   => "infospace",
    enterprise_number => 123,
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP IPv6 OptionSpace object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the name.
$ipv6os->name("info_space");
#Submit modification
my $response = $session->modify( $ipv6os );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP IPv6 OptionSpace object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` to retrieve the specific DHCP IPv6 OptionSpace object, and then submit this object for removal.

Example

```
#Get DHCP IPv6 OptionSpace object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6OptionSpace",
    name   => "info_space",
    enterprise_number => 123,
);
#Find the desired object from the retrieved list.
my $desired_option_space = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_option_space );
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 OptionSpace object:

 name     - Optional. Option space name in string format.
 comment  - Optional. Option space comment (regular expression).
 enterprise_number - Optional. Enterprise number.
```

Example

```
#Get DHCP IPv6 OptionSpace object through the session
my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::IPv6OptionSpace",
    comment => ".*comm.*"
);
```

METHODS

This section describes all the methods that can used to set and retrieve the attribute values of a DHCP IPv6 OptionSpace object.

name( )

Use this method to set or retrieve name of IPv6 option space object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name in string format with a maximum of 256 bytes.

Returns

If parameter is specified, the method returns true when the modification succeeds, and returns false when the operation fails.

If parameter is not specified, the method returns the attribute value.

Example

```
#Get name
my $name = $ipv6os->name();
#Modify name
$ipv6os->name("info_space");
```

comment( )

Use this method to set or retrieve a comment about the IPv6 option space object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If the parameter is specified, the method returns true when the modification succeeds, and returns false when the operation fails.

If the parameter is not specified, the method returns the attribute value.

Example

```
#Get comment
my $comment = $ipv6os->comment();
#Modify comment
$ipv6os->comment("my comment");
```

enterprise_number( )

Use this method to set or retrieve the enterprise number for the IPv6 option space object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An unsigned integer that represents the enterprise number.

Returns

If the parameter is specified, the method returns true when the modification succeeds, and returns false when the operation fails.

If the parameter is not specified, the method returns the attribute value.

Example

```
#Get enterprise_number
my $enterprise_number = $ipv6os->enterprise_number();
#Modify enterprise_number
$ipv6os->enterprise_number(345);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an IPv6OptionSpace object, such as get, add, modify and remove. Also sample includes error handling for the operations.

#Preparation prior to a DHCP IPv6OptionSpace object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
```

```
unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an IPv6OptionSpace object

```
my $ipv6os = Infoblox::DHCP::IPv6OptionSpace->new (
       "name" => "infospace"
);

unless($ipv6os) {
     die("Construct IPv6 option_space filter failed: ",
          Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "IPv6OptionSpace object created successfully\n";

#Verify if the DHCP IPv6OptionSpace exists in the Infoblox appliance
my $object = $session->get(
       object => "Infoblox::DHCP::IPv6OptionSpace",
       name   => "infospace"
       enterprise_number => 123,
);
unless ($object) {
   print "IPv6 option space does not exist on server, safe to add the option_space\n";
   $session->add($ipv6os)
      or die("Add IPv6 option space failed: ",
             $session->status_code() . ":" . $session->status_detail());
}
print "DHCP IPv6 OptionSpace added successfully\n";
```

#Get and Modify an IPv6OptionSpace object

```
#Get IPv6OptionSpace object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6OptionSpace",
    name   => "infospace"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get IPv6OptionSpace object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get IPv6OptionSpace object found at least 1 matching entry\n";

#Modify name of the obtained IPv6OptionSpace object
$object->name("info_space");

#Apply the changes
$session->modify($object)
    or die("Modify IPv6OptionSpace object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "IPv6OptionSpace object modified successfully \n";
```

#Remove an IPv6OptionSpace object

```
#Get IPv6OptionSpace object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6OptionSpace",
    name   => "info_space"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get IPv6OptionSpace object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get IPv6OptionSpace object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove IPv6OptionSpace object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "IPv6OptionSpace object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::IPv6Range - DHCP IPv6 Range object.

DESCRIPTION

A DHCP IPv6 range defines the specified range of IP addresses in an IPv6 network. A DHCP IPv6 range should be added for an IPv6 network so the Infoblox appliance can assign IP addresses within that specified range to DHCP clients. If the client is on an IPv6 network that is assigned a DHCP IPv6 range, the device distributes an available IP address from that range to the DHCP client, or to a DHCP relay agent if the request came through an agent. The DHCP IPv6 range should also be assigned with a device. If devices are in a grid, the particular member serving DHCP for the DHCP IPv6 range must be specified. If the server is an independent device, this device must be specified as the member that serves the DHCP IPv6 range.

CONSTRUCTOR

```
 my $dhcp_ipv6_range = Infoblox::DHCP::IPv6Range->new(
     network                          => $network,                                  #Required
     ipv6_end_prefix                  => $ipv6addr,                                 #Optional / See
NOTE below
```

```
     ipv6_prefix_bits                    => $num,                                  #Optional / See
NOTE below
     ipv6_start_prefix                   => $ipv6addr,                             #Optional / See
NOTE below
     end_addr                            => $ipv6addr,                             #Optional / See
NOTE below
     start_addr                          => $ipv6addr,                             #Optional / See
NOTE below
     address_type                        => "ADDRESS" | "PREFIX" | "BOTH",         #Optional / Default
is undefined
     comment                             => $string,                               #Optional / Default
is undefined
     disable                             => "true" | "false",                      #Optional / Default
is "false"
     exclude                             => [$ExclusionRange1,$ExclusionRange2,...], #Optional / Default
is empty

is undefined
     extensible_attributes               => { $string => $string | $num, $string => [ $string | $num, ...
], ... } #Optional / Default is undefined
     member                              => $Member,                               #Optional / Default
is undefined
     name                                => $string,                               #Optional / Default
is undefined
     network_view                        => $NetworkView,                          #Optional / Default
is system-defined default network view
     override_recycle_leases             => "true" | "false"                       #Optional / Default
is "false"
     recycle_leases                      => "true" | "false",                      #Optional / Default
is "true"
     server_association_type             => "NONE" | "MEMBER"                      #Optional / Default
is undefined
     template                            => $string,                               #Optional / Default
is undefined
     discovery_blackout_setting          => $blackout,                             #Optional
     port_control_blackout_setting       => $blackout,                             #Optional
     override_blackout_setting           => "true" | "false",                      #Optional / Default
value is "false"
     same_port_control_discovery_blackout => "true" | "false",                     #Optional / Default
value is "false"
     subscribe_settings                  => $subscribe_settings,                   #Optional / Default
is undefined
     override_subscribe_settings         => 'true' | 'false',                      #Optional / Default
is 'false'
 );
```

NOTE: one or both of the start_addr/end_addr and ipv6_start_prefix/ipv6_end_prefix/ipv6_prefix_bits parameter sets is required.

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a DHCP IPv6 range object.

Infoblox::Session->add( )

Use this method to add a DHCP IPv6 range object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $dhcp_ipv6range = Infoblox::DHCP::IPv6Range->new(
                                                start_addr => "2001:db8:0:c000:0001::",
                                                end_addr   => "2001:db8:0:c000:0021::",
                                                network    => "2001:db8:0:c000::/51",
);

# Submit for addition
my $response = $session->add( $dhcp_ipv6range );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 range object:

  start_addr             - Optional. Starting IP address of the DHCP IPv6 range within the network.
  end_addr               - Optional. Ending IP address of the DHCP IPv6 range within the network.
  ipv6_start_prefix      - Optional. Starting prefix of the DHCP IPv6 range.
  ipv6_end_prefix        - Optional. Ending prefix of the DHCP IPv6.
  network_view           - Optional. Network view in which the DHCP IPv6 range is located. By
default, all network views are searched.
  extattrs               - Optional. A hash reference containing extensible attributes.
  extensible_attributes  - Optional. A hash reference containing extensible attributes.
  member                 - Optional. The member serving the range. The valid value is an
Infoblox::DHCP::Member object.
  name                   - Optional. The name of the DHCP IPv6 Range.
  network                - Optional. The IPv6 Network the range resides in.
  comment                - Optional. The descriptive comment.
  server_association_type - Optional. The server association type for the range.
```

Examples

```
my @retrieved_objs = $session->get(
                     object     => "Infoblox::DHCP::IPv6Range",
                     start_addr => "2001:db8:0:c000:0001::" );

my @retrieved_objs = $session->get(
                     object       => "Infoblox::DHCP::IPv6Range",
                     start_addr   => "2001:db8:0:c000:0001::",
                     network_view => "default" );

my @retrieved_objs = $session->get(
                     object                => "Infoblox::DHCP::IPv6Range",
                     extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify a DHCP IPv6 range object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use method to modify the comment.
$dhcp_ipv6range->comment("this is a modified comment");
# Submit modification
my $response = $session->modify( $dhcp_ipv6range );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP IPv6 range object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP IPv6 range object, and then submit this object for removal.

Example

```
# Get the objects with the same name
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::IPv6Range",
    start_addr   => "2001:db8:0:c000:0001::",
    newtork_view => "default" );
# Find the desired object from the retrieved list.
my $desired_dhcp_range = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_dhcp_range );
```

Infoblox::Session->search( )

Use this method to search for DHCP IPv6 range objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
Apply the following attributes to search for a DHCP IPv6 range object:

  start_addr             - Optional. Starting IP address of the DHCP IPv6 range within the network
(regular expression).
  end_addr               - Optional. Ending IP address of the DHCP IPv6 range within the network
(regular expression).
  ipv6_start_prefix      - Optional. Starting prefix of the DHCP IPv6 range (regular expression).
  ipv6_end_prefix        - Optional. Ending prefix of the DHCP IPv6 (regular expression).
```

```
  network_view           - Optional. Network view in which the DHCP IPv6 range is located. By
default, all network views are searched.
  extattrs               - Optional. A hash reference containing extensible attributes.
  extensible_attributes  - Optional. A hash reference containing extensible attributes.
  member                 - Optional. The member serving the range. The valid value is an
Infoblox::DHCP::Member object.
  name                   - Optional. The name of the DHCP IPv6 Range (regular expression).
  network                - Optional. The IPv6 Network the range resides in (regular expression).
  comment                - Optional. The descriptive comment (regular expression).
  server_association_type - Optional. The server association type for the range.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# search for DHCP IPv6 range object with start address having last octet as 1
my @retrieved_objs = $session->search(
    object     => "Infoblox::DHCP::IPv6Range",
    network       => "2001:db8:0:c000::/51",
    network_view  => "default",
    start_addr    => "0021",
    comment       => ".*comment" );

# search for DHCP IPv6 range objects defining "Santa Clara" for "Site" extensible attribute
my @retrieved_objs = $session->search(
    object                => "Infoblox::DHCP::IPv6Range",
    extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a DHCP IPv6 range.

address_type( )

Use this method to set or retrieve the address type of a DHCP IPv6 Range object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "ADDRESS", "PREFIX", or "BOTH". When the address type is "ADDRESS", values for the 'start_addr' and 'end_addr' members are required. When the address type is "PREFIX", values for 'ipv6_start_prefix', 'ipv6_end_prefix', and 'ipv6_prefix_bits' are required. When the address type is "BOTH", values for 'start_addr', 'end_addr', 'ipv6_start_prefix', 'ipv6_end_prefix', and 'ipv6_prefix_bits' are all required.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address_type
my $address_type = $dhcp_ipv6range->address_type();
#Modify address_type
$dhcp_ipv6range->address_type("PREFIX");
```

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $dhcp_ipv6range->comment();
```

```
#Modify comment
$dhcp_ipv6range->comment("Modifying the DHCP IPv6 range comment");
```

cloud_info( )

Use this method to set or retrieve cloud API related information for the Infoblox::DHCP::IPv6Range object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a Infoblox::Grid::CloudAPI::Info object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $dhcp_ipv6range->cloud_info();
# Modify cloud_info
$dhcp_ipv6range->cloud_info($cloud_info_object);
```

disable( )

Use this method to set or retrieve the disable flag of a DHCP IPv6 range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value for this field is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $dhcp_ipv6range->disable();
#Modify disable
$dhcp_ipv6range->disable("false");
```

discovery_basic_poll_setting( )

Use this method to set or retrieve the discovery_basic_poll_setting value of a DHCP IPv6 range.

Include the specified parameter to set the attribute value.

Parameter

The valid value is object of the Infoblox::Grid::Discovery::BasicPollSettings manpage.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_basic_poll_setting
my $discovery_basic_poll_setting = $dhcp_ipv6range->discovery_basic_poll_setting();
#Modify discovery_basic_poll_setting
$dhcp_ipv6range->discovery_basic_poll_setting($poll_setting);
```

discovery_member( )

Use this method to set or retrieve the discovery_member value of a DHCP IPv6 range.

Parameter

The discovery member name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_member
my $discovery_member = $dhcp_ipv6range->discovery_member();
#Modify discovery_member
$dhcp_ipv6range->discovery_member("test.localdomain");
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $dhcp_ipv6range->discover_now_status();
```

discovery_blackout_setting( )

Use this method to set or retrieve the discovery blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If port_control_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when discovery_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->discovery_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->discovery_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_blackout_setting
my $discovery_blackout_setting = $dhcp_ipv6range->discovery_blackout_setting();
#Modify discovery_blackout_setting
$dhcp_ipv6range->discovery_blackout_setting($blackout);
```

enable_discovery( )

Use this method to set or retrieve the enable_discovery value of a DHCP IPv6 range. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_discovery method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_enable_discovery attribute to "false".

Enable this flag if you want to set discovery for this object.

Parameter

Specify "true" to set the enable_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_discovery
my $enable_discovery = $dhcp_ipv6range->enable_discovery();
#Modify enable_discovery
$dhcp_ipv6range->enable_discovery("false");
```

enable_immediate_discovery( )

Use this method to set or retrieve enable_immediate_discovery value of a DHCP IPv6 range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_immediate_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_immediate_discovery
my $enable_immediate_discovery = $dhcp_ipv6range->enable_immediate_discovery();
#Modify enable_immediate_discovery
$dhcp_ipv6range->enable_immediate_discovery("false");
```

end_addr( )

Use this method to set or retrieve the end address of the DHCP IPv6 range.

An end address is the last IP address in the DHCP IPv6 range available for the clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the end address of the DHCP IPv6 range in lowercase.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get end_addr
my $end_addr = $dhcp_ipv6range->end_addr();
#Modify end_addr
$dhcp_ipv6range->end_addr("2001:db8:0:c000:0021::");
```

endpoint_sources( )

Use this method to retrieve the list of endpoints that provide object data. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an array of Infoblox::CiscoISE::Endpoint objects.

Example

```
#Get endpoint_sources value
my $endpoint_sources = $object->endpoint_sources();
```

exclude( )

Use this method to set or retrieve the exclusion range of IP addresses in the DHCP IPv6 range which should not be assigned to clients.

If static addresses in the middle of a DHCP IPv6 range are assigned to certain hosts, those addresses can be excluded from the DHCP IPv6 range using this method.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::ExclusionRange objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get exclude
my $ref_exclude = $dhcp_ipv6range->exclude();
#Modify exclude
$dhcp_ipv6range->exclude([$exl1]); #$exl1 is an Infoblox::DHCP::ExclusionRange object
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP IPv6 range object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $dhcp_ipv6range->extattrs();
#Modify extattrs
$dhcp_ipv6range->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP IPv6 range object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $dhcp_ipv6range->extensible_attributes();
#Modify extensible attributes
$dhcp_ipv6range->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

ipv6_end_prefix( )

Use this method to set or retrieve the end prefix of the DHCP IPv6 range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the end prefix of the DHCP IPv6 range in lowercase.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_end_prefix
my $ipv6_end_prefix = $dhcp_ipv6range->ipv6_end_prefix();
#Modify ipv6_end_prefix
$dhcp_ipv6range->ipv6_end_prefix("2001:db8:0:c000:0021::");
```

ipv6_prefix_bits( )

Use this method to set or retrieve the prefix bits for the DHCP IPv6 range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An unsigned integer between 2 and 128.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_prefix_bits
my $ipv6_prefix_bits = $dhcp_ipv6range->ipv6_prefix_bits();
#Modify ipv6_prefix_bits
$dhcp_ipv6range->ipv6_prefix_bits(32);
```

ipv6_start_prefix( )

Use this method to set or retrieve the start prefix of the DHCP IPv6 range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the start prefix of the DHCP IPv6 range in lowercase.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_start_prefix
my $ipv6_start_prefix = $dhcp_ipv6range->ipv6_start_prefix();
#Modify ipv6_start_prefix
$dhcp_ipv6range->ipv6_start_prefix("2001:db8:0:c000:0011::");
```

member( )

Use this method to set or retrieve the member that serves DHCP for this IP address range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

If the attribute is set, the server_association_type attribute will also be set: to "MEMBER" if setting member to a defined value, to "NONE" otherwise.

Parameter

The valid value is a defined Infoblox::DHCP::Member object. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member
my $ref_member = $dhcp_ipv6range->member();
#Modify member
$dhcp_ipv6range->member($member1); #$member is an Infoblox::DHCP::Member object
```

name( )

Use this method to set or retrieve a descriptive name for the DHCP IPv6 range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The desired name in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $dhcp_ipv6range->name();
#Modify name
$dhcp_ipv6range->name("external");
```

network( )

Use this method to set or retrieve the DHCP IPv6 network of the address range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The DHCP IPv6 Network.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network
my $network = $dhcp_ipv6range->network();
#Set the network
$dhcp_ipv6range->network("2001:db8:0:c000::/51");
```

network_view( )

Use this method to set or retrieve the network view of the DHCP IPv6 range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the DHCP IPv6 range is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $dhcp_ipv6range->network_view();
#Modify network view, with an Infoblox::DHCP::View object
```

```
$dhcp_ipv6range->network_view($nview);
```

next_available_ip( )

Use this method to get the next available IPv6 address(es) in the DHCP IPv6 range object. Note that to use this method, the object MUST be retrieved via a get or search call, or created with an add call.

Parameter

The method accepts the following optional parameters:

```
  requested_num - The number of IP addresses requested. It must be a value between 1 and 20,
inclusive.
  excluded - A reference to an array of addresses to be excluded from the results.
```

Returns

This method returns the next available IPv6 address(es) in the range. If requested_num is not specified, a string with the next available address will be returned; otherwise, the method will return a reference to an array of addresses.

Within a DHCP Range object, the next available IP address(es) are the first addresses in this range that match all of the following rules:

```
   * Are not part of the passed 'excluded' parameter (if specified).
   * There is no fixed address or host address record with this IP address
   * There is no unmanaged record with this IP address
   * The IP address is not in any excluded range of this IPv6 DHCP range
   * There is no active lease with this IP address (Deleted leases in the recycle bin are not
considered.)
```

Example

```
# Retrieve a particular range
my @retrieved_objs = $session->get(
                        object     => "Infoblox::DHCP::IPv6Range",
                        start_addr => "10:9::"
);

$range = $retrieved_objs[0];

# Print the next available IPv6 address in the range
print $range->next_available_ip() . "\n";

# This will retrieve the next 10 available addresses and print the first one.
my $addressesref = $range->next_available_ip(requested_num => 10);
print @$addressesref[0] . "\n";

# This will retrieve the next 10 available addresses and exclude two.
my $addressesref = $range->next_available_ip(requested_num => 10, excluded => ["10:9::2",
"10:9::3"]);
```

override_blackout_setting( )

The override_blackout_setting attribute controls whether the discovery_blackout_setting and port_control_blackout_setting values in the object are used, instead of the grid default.

The override_blackout_setting attribute can be specified explicitly. It is also set implicitly when discovery_blackout_setting or port_control_blackout_setting is set to a defined value.

Parameter

Specify "true" to set the override_blackout_setting flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $dhcp_range->override_blackout_setting();
# Modify attribute value
$dhcp_range->override_blackout_setting('true');
```

override_recycle_leases( )

The override_recycle_leases attribute controls whether the recycle_leases value in the DHCP IPv6 Range is used, instead of the grid

default.

The override_recycle_leases attribute can be specified explicitly. It is also set implicitly when recycle_leases is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for recycle_leases. Set the parameter to "false" to inherit the grid-level setting for recycle_leases.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_recycle_leases
my $override_recycle_leases=$dhcp_ipv6range->override_recycle_leases( );
#Modifying override_recycle_leases
$dhcp_ipv6range->override_recycle_leases("true");
```

override_subscribe_settings( )

The override_subscribe_settings attribute controls whether the subscribe_settings method values of the member are used, instead of the Grid default.

The override_subscribe_settings attribute can be specified explicitly. It is also set implicitly when subscribe_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for subscribe_settings. Set the parameter to "false" to inherit the Grid-level setting for subscribe_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_subscribe_settings value
my $override_subscribe_settings = $object->override_subscribe_settings( );
#Modify override_subscribe_settings value
$object->override_subscribe_settings("true");
```

port_control_blackout_setting

Use this method to set or retrieve the port control blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when port_control_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->port_control_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->port_control_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get port_control_blackout_setting
my $port_control_blackout_setting = $dhcp_ipv6range->port_control_blackout_setting();
#Modify port_control_blackout_setting
$dhcp_ipv6range->port_control_blackout_setting($blackout);
```

restart_if_needed( )

Use this method to set the flag that indicates whether DHCP service should be restarted on a member that is serving DHCP for the changed object referenced in a cloud API request.

Parameter

Specify true to restart the DHCP service.

Returns

None

Example

```
# Modify
$network->restart_if_needed('true');
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag of the DHCP IPv6 range.

If the flag is enabled, the leases are kept in recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Setting this method to a defined value implicitly sets the override_recycle_leases method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_recycle_leases attribute to "false".

Note that when recycle_leases is set to a defined value and override_recycle_leases is set to "false", the last operation takes precedence. Thus the sequence $object->recycle_leases("true"); $object->override_recycle_leases("false"); will set override_recycle_leases to "false", and the sequence $objct->override_recycle_leases("false"); $object->recycle_leases("true"); will result in override_recycle_leases="true".

Parameter

Specify "true" to set the recycle_leases flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $dhcp_ipv6range->recycle_leases();
#Modify recycle_leases
$dhcp_ipv6range->recycle_leases("false");
```

same_port_control_discovery_blackout( )

Use this method to set or retrieve the flag that enables using the same discovery blackout for port control blackout.

Parameter

Specify 'true' to use same discovery blackout for port control blackout or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $dhcp_ipv6range->same_port_control_discovery_blackout();
# Modify attribute value
$dhcp_ipv6range->same_port_control_discovery_blackout('true');
```

server_association_type( )

Use this method to set or retrieve the DHCP IPv6 range server association type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The server_association_type attribute can be specified explicitly. It is also set implicitly when member is set.

Parameter

Valid values are "NONE" and "MEMBER".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get server_association_type
my $server_association_type = $dhcp_ipv6range->server_association_type();
#Modify server_association_type
$dhcp_ipv6range->server_association_type("MEMBER");
```

start_addr( )

Use this method to set or retrieve the start address of the DHCP IPv6 range.

A start address is the first IP address in the DHCP IPv6 range available for the clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the start address of the DHCP IPv6 range in lowercase.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get start_addr
my $start_addr = $dhcp_ipv6range->start_addr();
#Modify start_addr
$dhcp_ipv6range->start_addr("2001:db8:0:c000:0001::");
```

subscribe_settings( )

Use this method to set or retrieve the Cisco ISE subscribe settings.

Setting this method to a defined value implicitly sets the override_subscribe_settings method to "true". Setting the parameter to undefined causes the appliance to use the Cisco ISE endpoint default and automatically resets the override_subscribe_settings method to "false".

Note that when subscribe_settings is set to a defined value and override_subscribe_settings is set to "false", the last operation takes precedence. Thus the sequence $object->subscribe_settings($value); $object->override_subscribe_settings("false"); will set override_subscribe_settings to "false", and the sequence $object->override_subscribe_settings("false"); $object->subscribe_settings($value); will result in override_subscribe_settings="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::CiscoISE::SubscribeSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscribe_settings value
my $subscribe_settings = $object->subscribe_settings();
#Modify subscribe_settings value
$object->subscribe_settings($settings);
```

template( )

Use this method to set or retrieve the DHCP IPv6 range template name for a DHCP IPv6 Range object.

Template is the name of a DHCP IPv6 range template which will be used to create the DHCP IPv6 range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

The template parameter can be used to only add a new DHCP IPv6 range and cannot be used during object modify or returned during object get.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get template
my $template = $dhcp_ipv6range->template();
#Modify template
$dhcp_ipv6range->template("Template_Name");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP IPv6 range object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP IPv6 Range object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a DHCP Member object
my $memberdhcp = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2"
);
unless($memberdhcp) {
       die("Construct member failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Member object created successfully\n";

#Create the Network object with the member
my $network = Infoblox::DHCP::IPv6Network->new(
    network => "2001:db8:0:a000::/51",
    comment => "add network",
    members => [ $memberdhcp ]
);
unless($network) {
       die("Construct Network object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network object created successfully\n";

#Add the Network object into the Infoblox appliance through a session
$session->add($network)
```

```
    or die("Add Network object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "Network object added to Infoblox appliance successfully\n";

#Construct exclusion range object
my $exclusion_range = Infoblox::DHCP::ExclusionRange->new(
    start_address => "2001:db8:0:a000:0001::1a",
    end_address   => "2001:db8:0:a000:0001::fa",
    comment       => "Excluded range"
);
```

#Create a DHCP IPv6 Range object

```
my $dhcp_range = Infoblox::DHCP::IPv6Range->new(
                                        start_addr => '2001:db8:0:a000:0001::',
                                        end_addr   => '2001:db8:0:a000:0021::',
                                        network    => '2001:db8:0:a000::/51',
                                        comment    => 'Random comment',
                                        disable    => 'true',
                                        exclude => [$exclusion_range],
                                        ipv6_start_prefix       => '2001:db8:0:c001:0001::',
                                        ipv6_end_prefix         => '2001:db8:0:c001:0021::',
                                        ipv6_prefix_bits        => 12,
                                        member                  => $memberdhcp,
                                        name                    => 'randomrange',
                                        override_recycle_leases => 'true',
                                        recycle_leases          => 'false',
                                        server_association_type => 'MEMBER',
);
unless($dhcp_range) {
       die("Construct DHCP IPv6 Range object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP IPv6 Range object created successfully\n";

#Add the DHCP IPv6 Range object into the Infoblox appliance through a session
$session->add($dhcp_range)
    or die("Add DHCP IPv6 Range object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP IPv6 Range object added to the network successfully\n";
```

#Create a DHCP IPv6 Range object using a template

```
my $dhcp_range_template = Infoblox::DHCP::IPv6RangeTemplate->new(
        name                    => "custom_range_template",
        offset                  => "10",
        number_of_addresses     => "90",
);

NAME

Infoblox::DHCP::IPv6RangeTemplate - DHCP IPv6 RangeTemplate object.

DESCRIPTION

A DHCP IPv6 range template contains a set of predefined properties and can be used to create DHCP IPv6 ranges in a quick and consistent way. The DHCP IPv6 range created from a DHCP IPv6 range template will inherit the properties defined in the template.

CONSTRUCTOR

```
 my $ipv6_range_template = Infoblox::DHCP::IPv6RangeTemplate->new(
             name                    => $string,                                    #Required
             number_of_addresses     => $num,                                       #Required
             offset                  => $num,                                       #Required
             comment                 => $string,                                    #Optional / Default is
undefined
             exclude                 => [$ExclusionRange1, $ExclusionRange2,...],   #Optional / Default is
empty
             extattrs                => { $string => $extattr, ... },               #Optional / Default is
undefined
             extensible_attributes   => { $string => $string | $num, $string => [ $string | $num, ... ],
... }, #Optional / Default is undefined
             member                  => $Member,                                    #Optional / Default is
undefined
             override_recycle_leases => "true" | "false",                           #Optional / Default is
"false"
             recycle_leases          => "true" | "false" | undef,                   #Optional / Default is
undefined
             server_association_type => "NONE" | "MEMBER",                          #Optional / Default is
"NONE"
  );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

MODULE METHODS

The following functions can be applied to a DHCP IPv6 range template object.

Infoblox::DHCP::IPv6NetworkTemplate->range_templates( )

Use this function to include a range template in an IPv6 network template on the Infoblox appliance. See Infoblox::DHCP::IPv6NetworkTemplate->range_templates() for parameters and return values.

Example

```
#Construct an IPv6 range template object
my $ipv6_range_template = Infoblox::DHCP::IPv6RangeTemplate->new(
            name                    => "custom_range_template",
            number_of_addresses     => "1000",
            offset                  => "10",
    );

my $template = Infoblox::DHCP::Template->new(
            name                    => "custom_range_template",
    );

#Configure a range template in a network template object
my $responce = $network_template->range_templates([$template]);
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that can be applied to a DHCP IPv6 range template object.

Infoblox::Session->add( )

Use this method to add a DHCP IPv6 range template object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $ipv6_range_template = Infoblox::DHCP::IPv6RangeTemplate->new(
        name                    => "custom_range_template",
        offset                  => "20",
        number_of_addresses     => "100",
        comment                 => "add range",
        exclude                 => [$exclusion_range_template],
        member                  => $memberdhcp,
        recycle_leases          => "false",
        override_recycle_leases => "true",
        server_association_type => 'MEMBER',
);

# Submit for addition
my $response = $session->add( $ipv6_range_template );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP IPv6 range template object:

name - Optional. The name of the DHCP IPv6 range template.
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
server_association_type - Optional. The server association type for the range.
```

Examples

```
my @retrieved_objs = $session->get(
                      object => "Infoblox::DHCP::IPv6RangeTemplate",
                      name   => "custom_range_template"
                      );

my @retrieved_objs = $session->get(
                     object               => "Infoblox::DHCP::IPv6RangeTemplate",
                     extensible_attributes => { 'Site' => 'Santa Clara' }
                    );
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and

return values.

Key References

```
Apply the following attributes to search for a specific DHCP IPv6 range template object:

name    - Optional. The name of the DHCP IPv6 range template (regular expression).
comment - Optional. The comment of the DHCP IPv6 range template (regular expression).
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
server_association_type - Optional. The server association type for the range.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
my @retrieved_objs = $session->search(
                        object  => "Infoblox::DHCP::IPv6RangeTemplate",
                        name    => "custom_range_template",
                        comment => ".*",
        );

my @retrieved_objs = $session->search(
                        object               => "Infoblox::DHCP::IPv6RangeTemplate",
                        extensible_attributes => { 'Site' => 'Santa Clara' }
        );
```

Infoblox::Session->modify( )

Use this method to modify a DHCP IPv6 range template object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use this method to modify the comment.
$ipv6_range_template->comment("this is a modified comment");
# Submit modification
my $response = $session->modify( $ipv6_range_template );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP IPv6 range template object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP IPv6 range template object, and then submit this object for removal.

Example

```
# Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::IPv6RangeTemplate",
    name   => "custom_range_template"
    );

# Find the desired object from the retrieved list.
my $desired_ipv6_range_template = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_ipv6_range_template );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP IPv6 range template object.

comment( )

Use this method to set or retrieve a descriptive comment of a DHCP IPv6 range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $ipv6_range_template->comment();
#Modify comment
$ipv6_range_template->comment("Modifying the DHCP IPv6 range template comment");
```

exclude( )

Use this method to set or retrieve the exclusion range template in the DHCP IPv6 range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::ExclusionRangeTemplate objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get exclude
my $ref_exclude = $ipv6_range_template->exclude();
#Modify exclude
$ipv6_range_template->exclude([$exl1]); #$exl1 is an Infoblox::DHCP::ExclusionRangeTemplate
object
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP IPv6 range template object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $ipv6_range_template->extattrs();
#Modify extattrs
$ipv6_range_template->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP IPv6 range template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $ipv6_range_template->extensible_attributes();
#Modify extensible attributes
$ipv6_range_template->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
```

```
    'Tom' ] });
```

member( )

Use this method to set or retrieve the grid member assigned to the DHCP IPv6 range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a defined Infoblox::DHCP::Member object. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member
my $ref_member = $ipv6_range_template->member();
#Modify member
$ipv6_range_template->member($member1); #$member is an Infoblox::DHCP::Member object
```

name( )

Use this method to set or retrieve the name of the DHCP IPv6 range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the IPv6 range template in string format with a maximum of 64 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $ipv6_range_template->name();
#Modify name
$ipv6_range_template->name("custom_range_template");
```

number_of_addresses( )

Use this method to set or retrieve the number of addresses in this DHCP IPv6 range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of addresses in this DHCP IPv6 range template.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get number_of_addresses
my $number_of_addresses = $ipv6_range_template-> number_of_addresses();
#Modify number_of_addresses
$ipv6_range_template->number_of_addresses("100");
```

offset( )

Use this method to set or retrieve the address offset of this DHCP IPv6 range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The address offset of this DHCP IPv6 range template. The offset is calculated from the start address of the IPv6 network template that includes the DHCP range template. For example, in the IPv6 network 2010:0:0:10::/64, if the offset is set to 10 and number_of_addresses is set to 100, then the start address of the DHCP IPv6 range created from this range template is 2010:0:0::A and the end address is 2010:0:0::6D.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get offset
my $offset = $ipv6_range_template->offset();
#Modify offset
$ipv6_range_template->offset("10");
```

override_recycle_leases( )

The override_recycle_leases attribute controls whether the recycle_leases value in the DHCP IPv6 range template is used, instead of the grid default.

The override_recycle_leases attribute can be specified explicitly. It is also set implicitly when recycle_leases is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for recycle_leases. Set the parameter to "false" to inherit the grid-level setting for recycle_leases.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_recycle_leases
my $override_recycle_leases=$ipv6_range_template->override_recycle_leases( );
#Modifying override_recycle_leases
$ipv6_range_template->override_recycle_leases("true");
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag of the DHCP IPv6 range template.

If the flag is enabled, the leases are kept in the recycle bin until one week after they expire. When the flag is disabled, the leases are irrecoverably deleted.

Setting this method to a defined value implicitly sets the override_recycle_leases method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_recycle_leases attribute to "false".

Note that when recycle_leases is set to a defined value and override_recycle_leases is set to "false", the last operation takes precedence. Thus the sequence $object->recycle_leases("true"); $object->override_recycle_leases("false"); will set override_recycle_leases to "false", and the sequence $objct->override_recycle_leases("false"); $object->recycle_leases("true"); will result in override_recycle_leases="true".

Parameter

Specify "true" to set the recycle_leases flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $ipv6_range_template->recycle_leases();
#Modify recycle_leases
$ipv6_range_template->recycle_leases("false");
```

server_association_type( )

Use this method to set or retrieve the DHCP IPv6 range template server association type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "NONE" and "MEMBER".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get server_association_type
my $server_association_type = $ipv6_range_template->server_association_type();
#Modify server_association_type
$ipv6_range_template->server_association_type("MEMBER");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP range template object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP IPv6RangeTemplate object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
               master   => "192.168.1.2",      #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a DHCP Member object
my $memberdhcp = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2"
);
unless($memberdhcp) {
       die("Construct member failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Member object created successfully\n";

#Construct exclusion range template object
my $exclusion_range_template = Infoblox::DHCP::ExclusionRangeTemplate->new(
    offset              => "15",
    number_of_addresses => "50",
    comment             => "Excluded range"
);
unless($exclusion_range_template){
       die("Construct exclusion range template object failed: ",
                Infoblox::status_code() . ":" . Infoblox::status_detail());
       }
 print "Exclusion range template object created successfully\n";
```

#Create a DHCP IPv6 range template object

```
my $ipv6_range_template = Infoblox::DHCP::IPv6RangeTemplate->new(
        name                  => "custom_range_template",
        offset                => "20",
        number_of_addresses   => "100",
        comment               => "add range",
```

```
        exclude                 => [$exclusion_range_template],
        member                  => $memberdhcp,
        recycle_leases          => "false",
        override_recycle_leases => "true",
        server_association_type => 'MEMBER',
);
unless($ipv6_range_template) {
       die("Construct DHCP IPv6 range template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP IPv6 range template object created successfully\n";

#Add the DHCP IPv6 range template object into the Infoblox appliance through a session
$session->add($ipv6_range_template)
    or die("Add DHCP IPv6 range template object failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "DHCP IPv6 range template object added to the network successfully\n";
```

#Get and modify a DHCP IPv6 range template

```
#Get a DHCP IPv6 range template through the session
my @retrieved_objs = $session->get(
    object     => "Infoblox::DHCP::IPv6RangeTemplate",
    name       => "custom_range_template",
);
my $object = $retrieved_objs[0];
unless ($object) {
       die("Get DHCP IPv6 range template failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get DHCP IPv6 range template object found at least 1 matching entry\n";

#Modify one of the attributes of the specified DHCP IPv6 range template
$object->comment("modified comment");

#Apply the changes
$session->modify($object)
    or die("Modify DHCP IPv6 range template failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "DHCP IPv6 range template object modified successfully \n";
```

#Remove a DHCP IPv6 range template

```
#Get a DHCP IPv6 range template through the session
my @retrieved_objs = $session->get(
    object     => "Infoblox::DHCP::IPv6RangeTemplate",
    name       => "custom_range_template",
);

my $object = $retrieved_objs[0];
unless ($object) {
       die("Get DHCP IPv6 range template failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get DHCP IPv6 range template object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove DHCP IPv6 range template failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "DHCP IPv6 range template object removed successfully \n";

####PROGRAM ENDS####
```

NAME

Infoblox::DHCP::IPv6SharedNetwork - DHCP IPv6 Shared Network object

---

DESCRIPTION

You can create a shared network when two subnets share a particular network segment. Before creating a shared network, you must first create the subnetworks. For example, you must first create the networks 2001:10:20:: and 2001:10:30:: before designating them as a shared network.

CONSTRUCTOR

```
  my $sharednetwork = Infoblox::DHCP::IPv6SharedNetwork->new(
         name                              => $string,                    #Required
         networks                          => [ $Network1,$Network2,...], #Required
         comment                           => $string | undef,            #Optional / Default is
undefined
         ddns_domainname                   => $string | undef,            #Optional / Default is
undefined
         ddns_enable_option_fqdn           => "true" | "false",           #Optional / Default is "false"
         ddns_generate_hostname            => "true" | "false",           #Optional / Default is "false"
         ddns_ttl                          => $num,                       #Optional / Default is 0
         disable                           => "true" | "false",           #Optional / Default is "false"
         domain_name                       => $string | undef,            #Optional / Default is
```

```
undefined
        domain_name_servers                 => "$ipv6addr,$ipv6addr,...",  #Optional / Default is
undefined
        enable_ddns                         => "true" | "false" | undef,   #Optional / Default is
undefined
        extattrs                            => { $string => $extattr, ... },      #Optional / Default is
undefined
        extensible_attributes               => { $string => $string | $num, $string => [ $string | $num,
... ], ... }, #Optional / Default is undefined.
        network_view                        => $NetworkView,               #Optional / Default is
"default" network view
        options                             => [$Option1,$Option2,...],    #Optional / Default is empty
list
        override_ddns_domainname            => "true" | "false",           #Optional / Default is "false"
        override_ddns_enable_option_fqdn    => "true" | "false",           #Optional / Default is "false"
        override_ddns_generate_hostname     => "true" | "false",           #Optional / Default is "false"
        override_ddns_ttl                   => "true" | "false",           #Optional / Default is "false"
        override_domain_name                => "true" | "false",           #Optional / Default is "false"
        override_domain_name_servers        => "true" | "false",           #Optional / Default is "false"
        override_enable_ddns                => "true" | "false",           #Optional / Default is "false"
        override_options                    => "true" | "false",           #Optional / Default is "false"
        override_preferred_lifetime         => "true" | "false",           #Optional / Default is "false"
        override_update_dns_on_lease_renewal=> "true" | "false",           #Optional / Default is "false"
        override_valid_lifetime             => "true" | "false",           #Optional / Default is "false"
        preferred_lifetime                  => $num,                       #Optional / Default is 27000
        update_dns_on_lease_renewal         => "true" | "false" | undef,   #Optional / Default is
undefined
        valid_lifetime                      => $num,                       #Optional / Default is 43200
    );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a DHCP IPv6 shared network object.

Infoblox::Session->add( )

Use this method to add an IPv6 shared network object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct a network object
my $network1 = Infoblox::DHCP::IPv6Network->new(
        network => "2001:10:20:30::/64",
);

#Construct a shared network object
  my $sharednetwork = Infoblox::DHCP::IPv6SharedNetwork->new(
        name     => "myname",
        networks => [$network1],
);

# Submit for adding a shared network
my $response = $session->add( $sharednetwork );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching shared network objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP shared network object:

  name           - Required.    The name of the shared network in string format.
  network_view   - Optional.    The network view in which the shared network is located. By default,
all network views are searched.
  extattrs       - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
  my  @result_array = $session->get(
       object       => "Infoblox::DHCP::IPv6SharedNetwork" ,
       name         => "myname",
       network_view => "default"
```

```
);
```

Infoblox::Session->modify( )

Use this method to modify an IPv6 shared network object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use this method to modify the enable_ddns method.
$object->enable_ddns("true");
# Submit for modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove a shared network object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the object, and then submit it for removal.

Example

```
# Get the object under the same name
my  @result_array = $session->get(
      object       => "Infoblox::DHCP::IPv6SharedNetwork" ,
      name         => "myname",
      network_view => "default"
 );

# Find the desired object on the retrieved list
my $desired_network = $result_array[0];

# Submit for removal
my $response = $session->remove( $desired_network );
```

Infoblox::Session->search( )

Use this method to search for a DHCP shared network object in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a DHCP shared network object:

  name          - Required. The name of the shared network in string format (regular expression).
  network_view  - Optional. The network view in which the shared network is located. By default, all
network views are searched.
  extattrs      - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# Search for all DHCP shared networks in the "default" network view
    my @retrieved_objs = $session->search(
      object    => "Infoblox::DHCP::IPv6SharedNetwork",
      name      => "my.*",
      network_view => "default"
    );

# Search for all IPv6 shared networks with the extensible attribute 'Site'
    my @retrieved_objs = $session->search(
      object => "Infoblox::DHCP::IPv6SharedNetwork",
      extensible_attributes => { 'Site' => 'Santa Clara' }
    );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of DHCP a shared network object

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $sharednetwork->comment();
#Modify comment
$sharednetwork->comment("Modified shared network");
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_ddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $sharednetwork->ddns_domainname();
#Modify ddns_domainname
$sharednetwork->ddns_domainname("test_domain.com");
```

ddns_enable_option_fqdn( )

Use this method to set or retrieve the ddns_enable_option_fqdn flag of a shared network object. This method controls whether the FQDN option sent by the client is to be used, or if the server can automatically generate the FQDN. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_enable_option_fqdn method to "true". Setting the parameter to undefined causes the appliance to use the member default and automatically resets the override_ddns_enable_option_fqdn attribute to "false".

Note that when ddns_enable_option_fqdn is set to a defined value and override_ddns_enable_option_fqdn is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_enable_option_fqdn("true"); $object->override_ddns_enable_option_fqdn("false"); will set override_ddns_enable_option_fqdn to "false", and the sequence $object->override_ddns_enable_option_fqdn("false"); $object->ddns_enable_option_fqdn("true"); will result in override_ddns_enable_option_fqdn="true".

Parameter

Specify "true" to generate the host name or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute is inherited from the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_enable_option_fqdn
my $ddns_enable_option_fqdn = $sharednetwork->ddns_enable_option_fqdn()
# Modify ddns_enable_option_fqdn
$sharednetwork->ddns_enable_option_fqdn("true");
#Un-override
$sharednetwork->ddns_enable_option_fqdn(undef);
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a shared network object. Enable this method to allow only the DHCP server to generate host name. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_generate_hostname method to "true". Setting the parameter to undefined causes the appliance to use the upper-level setting and automatically resets the override_ddns_generate_hostname attribute to "false".

Note that when ddns_generate_hostname is set to a defined value and override_ddns_generate_hostname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_generate_hostname("true"); $object->override_ddns_generate_hostname("false"); will set override_ddns_generate_hostname to "false", and the sequence $object->override_ddns_generate_hostname("false"); $object->ddns_generate_hostname("true"); will result in override_ddns_generate_hostname="true".

Parameter

Specify "true" to generate the host name or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute is inherited from the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_generate_hostname
my $ddns_generate_hostname = $sharednetwork->ddns_generate_hostname()
# Modify ddns_generate_hostname
$sharednetwork->ddns_generate_hostname("true");
#Un-override
$sharednetwork->ddns_generate_hostname(undef);
```

ddns_ttl( )

Use this method to set or retrieve the DNS update Time to Live (TTL) value of an IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_dddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration,in seconds, that the update is cached. Zero indicates that the update should not be cached. The default value is zero.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get DNS Update TTL
my $dns_ttl = $sharednetwork->ddns_ttl();
#Modify DNS Update TTL
$sharednetwork->ddns_ttl(1200);
```

disable( )

Use this method to set or retrieve the disable flag of an IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag and disable the shared network or "false" to unset the flag and enable the IPv6 shared network. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get disable
my $disable = $sharednetwork->disable()
# Modify disable
$sharednetwork->disable("true");
```

domain_name( )

Use this method to set or retrieve the domain_name value of a DHCP IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_domain_name attribute to "false".

Note that when domain_name is set to a defined value and override_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name("testdomain"); $object->override_domain_name("false"); will set override_domain_name to "false", and the sequence $object->override_domain_name("false"); $object->domain_name("testdomain"); will result in override_domain_name="true".

Parameter

The name of the client's domain for resolving names in DNS in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name
my $domain_name = $sharednetwork->domain_name();
#Modify domain_name
$sharednetwork->domain_name("test_domain.com");
```

domain_name_servers( )

Use this method to set or retrieve the domain_name_servers value of a DHCP IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_domain_name_servers attribute to "false".

Note that when domain_name_servers is set to a defined value and override_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->domain_name_servers("2001::1,2001::2"); $object->override_domain_name_servers("false"); will set override_domain_name_servers to "false", and the sequence $object->override_domain_name_servers("false"); $object->domain_name_servers("2001::1,2001::2"); will result in override_domain_name_servers="true".

Parameter

A comma separated list of the domain name server addresses in IPv6 address format. Spaces around the commas are not allowed.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domain_name_servers
my $domain_name_servers = $sharednetwork->domain_name_servers();
#Modify domain_name_servers
$sharednetwork->domain_name_servers("2001::1,2001::2");
```

enable_ddns( )

Use this method to set or retrieve the dynamic DNS updates flag of a DHCP IPv6 shared network object. The DHCP server can send DDNS updates to DNS servers in the same grid and to external DNS servers. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_ddns method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_enable_ddns attribute to "false".

Note that when enable_ddns is set to a defined value and override_enable_ddns is set to "false", the last operation takes precedence. Thus the sequence $object->enable_ddns("true"); $object->override_enable_ddns("false"); will set override_enable_ddns to "false", and the sequence $object->override_enable_ddns("false"); $object->enable_ddns("true"); will result in override_enable_ddns="true".

Parameter

Specify "true" to set the dynamic DNS updates flag or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute is inherited from the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ddns
my $enable_ddns = $sharednetwork->enable_ddns()
# Modify enable_ddns
$sharednetwork->enable_ddns("true");
# Un-override enable_ddns
$sharednetwork->enable_ddns(undef);
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with an IPv6 shared network object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $sharednetwork->extattrs();
#Modify extattrs
$sharednetwork->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with an IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $shared_network->extensible_attributes();
#Modify extensible attributes
$shared_network->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

name( )

Use this method to retrieve the name of an IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the shared network in string format. A name can have a maximum of 32 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $sharednetwork = $sharednetwork->name();
```

networks( )

Use this method to retrieve the DHCP IPv6 networks associated with an IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::IPv6Network objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get networks
my $sharednetwork = $sharednetwork->networks();
#Modify networks
my $network1 = Infoblox::DHCP::IPv6Network->new(
                                    "network" => "2001:10:20:30::/64",
                                );
my $network2 = Infoblox::DHCP::IPv6Network->new(
                                    "network" => "2001:10:20:40::/64",
                                );
my $sharednetwork = $sharednetwork->networks([$network1, $network2]);
```

network_view( )

Use this method to set or retrieve the network view of the DHCP IPv6 shared network.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the DHCP shared network is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $sharednetwork->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$sharednetwork->network_view($nview);
```

options( )

Use this method to set or retrieve the options value of DHCP IPv6 shared network. DHCP options provide network configuration settings and various services available on the network for DHCP. This setting overrides the member-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_options method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_options attribute to "false".

Note that when the options method is set to a defined value and override_options is set to "false", the last operation takes precedence. Thus the sequence $object->options([$opt]); $object->override_options("false"); will set override_options to "false", and the sequence $object->override_options("false"); $object->options([$opt]); will result in override_options="true".

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $sharednetwork->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name   => "dhcp6.rapid-commit",
    value  => "true"
);
$sharednetwork->options([$option1]);
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$sharednetwork->override_ddns_domainname( );
#Modifying override_ddns_domainname
$sharednetwork->override_ddns_domainname("true");
```

override_ddns_enable_option_fqdn( )

The override_ddns_enable_option_fqdn attribute controls whether the enable_ddns value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_ddns_enable_option_fqdn attribute can be specified explicitly. It is also set implicitly when enable_ddns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ddns. Set the parameter to "false" to inherit the grid-level setting for enable_ddns.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_enable_option_fqdn
my $override_ddns_enable_option_fqdn=$sharednetwork->override_ddns_enable_option_fqdn( );
#Modifying override_ddns_enable_option_fqdn
$sharednetwork->override_ddns_enable_option_fqdn("true");
```

override_ddns_generate_hostname( )

The override_ddns_generate_hostname attribute controls whether the enable_ddns value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_ddns_generate_hostname attribute can be specified explicitly. It is also set implicitly when enable_ddns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ddns. Set the parameter to "false" to inherit the grid-level setting for enable_ddns.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_generate_hostname
my $override_ddns_generate_hostname=$sharednetwork->override_ddns_generate_hostname( );
#Modifying override_ddns_generate_hostname
$sharednetwork->override_ddns_generate_hostname("true");
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the DHCP shared network object is used, instead of the grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_ttl. Set the parameter to "false" to inherit the grid-level setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_ttl
my $override_ddns_ttl=$sharednetwork->override_ddns_ttl( );
#Modifying override_ddns_ttl
$sharednetwork->override_ddns_ttl("true");
```

override_domain_name( )

The override_domain_name attribute controls whether the domain_name value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_domain_name attribute can be specified explicitly. It is also set implicitly when domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for domain_name. Set the parameter to "false" to inherit the grid-level setting for domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_domain_name
my $override_domain_name=$sharednetwork->override_domain_name( );
#Modifying override_domain_name
$sharednetwork->override_domain_name("true");
```

override_domain_name_servers( )

The override_domain_name_servers attribute controls whether the domain_name_servers value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_domain_name_servers attribute can be specified explicitly. It is also set implicitly when domain_name_servers is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for domain_name_servers. Set the parameter to "false" to inherit the grid-level setting for domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_domain_name_servers
my $override_domain_name_servers=$sharednetwork->override_domain_name_servers( );
#Modifying override_domain_name_servers
$sharednetwork->override_domain_name_servers("true");
```

override_enable_ddns( )

The override_enable_ddns attribute controls whether the enable_ddns value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_enable_ddns attribute can be specified explicitly. It is also set implicitly when enable_ddns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ddns. Set the parameter to "false" to inherit the grid-level setting for enable_ddns.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_ddns
my $override_enable_ddns=$sharednetwork->override_enable_ddns( );
#Modifying override_enable_ddns
$sharednetwork->override_enable_ddns("true");
```

override_options( )

The override_options attribute controls whether the options value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_options attribute can be specified explicitly. It is also set implicitly when options is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_options
my $override_options=$sharednetwork->override_options( );
#Modifying override_options
$sharednetwork->override_options("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_preferred_lifetime
my $override_preferred_lifetime=$sharednetwork->override_preferred_lifetime( );
#Modifying override_preferred_lifetime
$sharednetwork->override_preferred_lifetime("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP shared network object is used, instead of the grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_update_dns_on_lease_renewal
my $override_update_dns_on_lease_renewal=$sharednetwork->override_update_dns_on_lease_renewal( );
#Modifying override_update_dns_on_lease_renewal
$sharednetwork->override_update_dns_on_lease_renewal("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the DHCP IPv6 shared network is used, instead of the grid default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for options. Set the parameter to "false" to inherit the grid-level setting for options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_valid_lifetime
my $override_valid_lifetime=$sharednetwork->override_valid_lifetime( );
#Modifying override_valid_lifetime
$sharednetwork->override_valid_lifetime("true");
```

preferred_lifetime( )

Use this method to set or retrieve the preferred lifetime of the DHCP IPv6 shared network object.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_preferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(20000); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(20000); will result in override_preferred_lifetime="true".

Parameter

Preferred lifetime value in seconds. The default value is 27000. Note that the preferred lifetime cannot be greater than the valid lifetime.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get preferred_lifetime
my $preferred_lifetime = $sharednetwork->preferred_lifetime();
#Modify preferred_lifetime
$sharednetwork->preferred_lifetime(12345);
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$sharednetwork->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$sharednetwork->update_dns_on_lease_renewal("true");
```

valid_lifetime( )

Use this method to set or retrieve the valid lifetime value of a DHCP IPv6 shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_valid_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_valid_lifetime attribute to "false".

Note that when valid_lifetime is set to a defined value and override_valid_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->valid_lifetime(691200); $object->override_valid_lifetime("false"); will set override_valid_lifetime to "false", and the sequence $object->override_valid_lifetime("false"); $object->valid_lifetime(691200); will result in override_valid_lifetime="true".

Parameter

A 32-bit integer (valid range from 1 to 4294967295) that represents the lifetime, in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid lifetime
my $valid_lifetime = $sharednetwork->valid_lifetime();
#Modify valid lifetime
$sharednetwork->valid_lifetime(864000);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP IPv6 shared network object insertion

```
#Create a session to the Infoblox device
my $session = Infoblox::Session->new(
    master   =>  "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
```

```
    die("Construct session failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a DHCP Network object>

my $network1 = Infoblox::DHCP::IPv6Network->new(
                                    "network" => "2001:10:20:30::/64",
                                );
my $network2 = Infoblox::DHCP::IPv6Network->new(
                                    "network" => "2001:10:20:40::/64",
                                );
my $response = $session->add($network1)
or die("Add \"2001:10:20:30::/64\"Network failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "Network \"2001:10:20:30::/64\"added successfully\n"; my $response = $session->add($network2)
       or die("Add  \"2001:10:20:30::/64\" Network failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "Network  \"2001:10:20:40::/64\",added successfully\n";
```

#Create a DHCP IPv6 Shared Network object

```
my $sharednetwork1 = Infoblox::DHCP::IPv6SharedNetwork->new(
                                    "name"                                => "myname",
                                    "comment"                             => "add shared network",

NAME

Infoblox::DHCP::Lease - DHCP Lease object.

DESCRIPTION

A DHCP lease provides information about the lease of an IP address to a DHCP client, such as the time when the Infoblox appliance issued or freed an IP address, the MAC address and host name of the client that received the IP address, and the grid member that supplied the lease. It allows the Infoblox appliance to store and correlate DHCP lease information over the lifetime of a lease.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that can be applied to a DHCP Lease object.

Infoblox::Session->get( )

Use this method to retrieve all the matching DHCP Lease objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
 Apply the following attributes to get a specific DHCP Lease object:

 ip_address                          - Optional. IPv4 or IPv6 address of the DHCP lease. Use this,
in place of ipv4addr, even for IPv4 addresses.
 ipv4addr                            - Optional. IPv4 address (32 bits) of the DHCP lease. This
attribute is being deprecated in favor of the ip_address attribute.
 ipv6_duid                           - Optional. IPv6 DUID of the DHCP lease. (For IPv6 leases
only)
 protocol                            - Optional. Specify whether to get IPv4, IPv6, or both leases.
Allowed values are: 'IPV4', 'IPV6', and 'BOTH'.
 start_addr                          - Optional. Start IPv4 or IPv6 address of the DHCP range.
 end_addr                            - Optional. End IPv4 or IPv6 address of the DHCP range.
 network_view                        - Optional. Name of the network view that contains the lease.
 mac                                 - Optional. MAC address of the DHCP lease. (For IPv4 leases
only)
 username                            - Optional. User name associated with the DHCP lease.
 client_hostname                     - Optional. Client hostname of a DHCP lease.
 fingerprint                         - Optional. DHCP fingerprint description.
 remote_id                           - Optional. Relay agent remote ID, a sub-option of DHCP option
82. (For IPv4 leases only)

 discovered_duid                     - Optional. Discovered DHCPv6 UID.
 discovered_name                     - Optional. Discovered name.
 discoverer                          - Optional. Discoverer name.
 first_discovered                    - Optional. Time of the first discovery.
 last_discovered                     - Optional. Time of the last discovery.
 netbios                             - Optional. Discovered NetBIOS name.
 network_component_description       - Optional. Discovered network component description.
 network_component_ip                - Optional. Discovered network component IP address.
 network_component_name              - Optional. Discovered network component name.
 network_component_port_description  - Optional. Discovered network component port description.
 network_component_port_name         - Optional. Discovered network component port name.
 network_component_port_number       - Optional. Discovered network component port number.
 network_component_type              - Optional. Discovered network component type.
 os                                  - Optional. Discovered OS.
 port_duplex                         - Optional. Discovered port duplex settings.
 port_link_status                    - Optional. Discovered port link status.
 port_speed                          - Optional. Discovered port speed settings.
 port_status                         - Optional. Discovered port status settings.
 port_vlan_description               - Optional. Discovered port VLAN description.
 port_vlan_name                      - Optional. Discovered port VLAN name.
 port_vlan_number                    - Optional. Discovered port VLAN number.
 v_cluster                           - Optional. Discovered VMware cluster name. (For IPv4 leases
only)
 v_datacenter                        - Optional. Discovered VMware datacenter name. (For IPv4
leases only)
 v_host                              - Optional. Discovered VMware server name. (For IPv4 leases
only)
 v_name                              - Optional. Discovered VMware host or virtual machine name.
(For IPv4 leases only)
 v_netadapter                        - Optional. Discovered VMware physical network adapter name.
(For IPv4 leases only)
 v_switch                            - Optional. Discovered VMware virtual switch name. (For IPv4
leases only)
 v_type                              - Optional. Discovered VMware entity type (possible values:
"VirtualMachine", "HostSystem", "VirtualCenter").
```

Example

```
#Get a DHCP lease by IP address.
```

```
my @retrieved_objs = $session->get(
                            object   => "Infoblox::DHCP::Lease",
                            ip_address => "10.0.0.10"
                            mac      => "22:22:22:22:22:22",
                            username => "johndoe"
                            );
my @retrieved_objs = $session->get(
                            object   => "Infoblox::DHCP::Lease",
                            ip_address => "2001::1"
                            username => "johndoe"
                            );

#Get DHCP leases in a DHCP range.
my @retrieved_objs = $session->get(
                            object     => "Infoblox::DHCP::Lease" ,
                            start_addr => "10.0.0.1",
                            end_addr   => "10.0.0.10"
                            );
my @retrieved_objs = $session->get(
                            object     => "Infoblox::DHCP::Lease" ,
                            start_addr => "2001::1",
                            end_addr   => "2001::5"
                            );

#Get DHCP leases by v_type:
my @retrieved_objs = $session->get(
  object    => 'Infoblox::DHCP::Lease',
  v_type    => 'VirtualMachine');
```

Infoblox::Session->remove( )

Use this method to remove a DHCP Lease object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Remove a DHCP IPv4 Lease object.
my $object = $session->get(
    object   => "Infoblox::DHCP::Lease",
    ip_address => "10.0.0.10"
    mac      => "22:22:22:22:22:22",
    username => "johndoe"
);
my $response = $session->remove($object);

#Remove a DHCP IPv6 Lease object.
my $object = $session->get(
    object   => "Infoblox::DHCP::Lease",
    ip_address => "2001::1"
    username => "johndoe"
);
my $response = $session->remove($object);
```

Infoblox::Session->search( )

Use this method to search for DHCP Lease objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
  Apply the following attributes to search for a DHCP Lease object:

  ip_address                          - Optional. IPv4 or IPv6 address of the DHCP lease. Use this,
in place of ipv4addr, even for IPv4 addresses (regular expression).
  ipv4addr                            - Optional. IPv4 address (32 bits) of the DHCP lease. This
attribute is being deprecated in favor of the ip_address attribute (regular exression).
  ipv6_duid                           - Optional. IPv6 DUID of the DHCP lease (regular expression).
(For IPv6 leases only)
  protocol                            - Optional. Specify whether to get IPv4, IPv6, or both
leases. Allowed values are: 'IPV4', 'IPV6', and 'BOTH'.
  mac                                 - Optional. MAC address of the DHCP lease (regular
expression). (For IPv4 leases only)
  network_view                        - Optional. Name of the network view that contains the lease.
  username                            - Optional. User name associated with the DHCP lease (regular
expression).
  start_addr                          - Optional. Start IPv4 or IPv6 address of the DHCP range.
  end_addr                            - Optional. End IPv4 or IPv6 address of the DHCP range.
```

```
  client_hostname                       - Optional. Client hostname of a DHCP lease (regular
expression).
  fingerprint                           - Optional. DHCP fingerprint description (regular
expression).
  remote_id                             - Optional. Relay agent remote ID, a sub-option of DHCP
option 82 (regular expression).

  discovered_duid                       - Optional. Discovered DHCPv6 UID (exact search only).
  discovered_name                       - Optional. Discovered name(regex).
  discoverer                            - Optional. Discoverer name(regex).
  first_discovered                      - Optional. Time of the first discovery (in ISO format, exact
search only).
  last_discovered                       - Optional. Time of the last discovery (in ISO format, exact
search only).
  netbios                               - Optional. Discovered NetBIOS name(regex).
  network_component_description         - Optional. Discovered network component description(regex).
  network_component_ip                  - Optional. Discovered network component IP address(regex).
  network_component_name                - Optional. Discovered network component name(regex).
  network_component_port_description    - Optional. Discovered network component port
description(regex).
  network_component_port_name           - Optional. Discovered network component port name(regex).
  network_component_port_number         - Optional. Discovered network component port number (exact
search only).
  network_component_type                - Optional. Discovered network component type(regex).
  os                                    - Optional. Discovered OS (regex).
  port_duplex                           - Optional. Discovered port duplex settings (exact search
only).
  port_link_status                      - Optional. Discovered port link status (exact search only).
  port_speed                            - Optional. Discovered port speed settings (exact search
only).
  port_status                           - Optional. Discovered port status settings (exact search
only).
  port_vlan_description                 - Optional. Discovered port VLAN description(regex).
  port_vlan_name                        - Optional. Discovered port VLAN name(regex).
  port_vlan_number                      - Optional. Discovered port VLAN number(exact search only).
  v_cluster                             - Optional. Discovered VMware cluster name (regular
expression). (For IPv4 leases only)
  v_datacenter                          - Optional. Discovered VMware datacenter name (regular
expression). (For IPv4 leases only)
  v_host                                - Optional. Discovered VMware server name (regular
expression). (For IPv4 leases only)
  v_name                                - Optional. Discovered VMware host or virtual machine name
(regular expression). (For IPv4 leases only)
  v_netadapter                          - Optional. Discovered VMware physical network adapter name
(regular expression). (For IPv4 leases only)
  v_switch                              - Optional. Discovered VMware virtual switch name (regular
expression). (For IPv4 leases only)
  v_type                                - Optional. Discovered VMware entity type (possible values:
"VirtualMachine", "HostSystem", "VirtualCenter"). (For IPv4 leases only)
```

Example

```
#Search a DHCP lease.
my @result_array = $session->search(
                    object   => "Infoblox::DHCP::Lease",
                    ip_address => "^10\.*",
                    mac      => "22:.*",
                    username => "john.*"
                    );
my @result_array = $session->search(
                    object   => "Infoblox::DHCP::Lease",
                    ip_address => "^ff::.*",
                    username => "john.*"
                    );

# search a DHCP lease by v_datacenter:
my @retrieved_objs = $session->search(
   object       => 'Infoblox::DHCP::Lease',
   v_datacenter => 'test.*');
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute value of a DHCP Lease object.

billing_class( )

Use this method to retrieve the billing_class of a DHCP Lease object. This method specifies the class to which this lease is currently billed. This method is for IPv4 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get billing_class
my $billing_class = $lease->billing_class();
```

binding_state( )

Use this method to retrieve the binding state for the current lease. The lease state can be one of the following:

```
 Free      : The lease is available for clients to use.
 Active    : The lease is currently in use by a DHCP client.
 Expired   : The lease was in use, but the DHCP client never renewed it, so it is no longer valid.
 Released  : The DHCP client returned the lease to the appliance.
 Abandoned: The Infoblox appliance cannot lease this IP address because the appliance received a response
when it pinged the address.
```

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get binding_state
my $binding_state = $lease->binding_state();
```

client_hostname( )

Use this method to retrieve the client_hostname of a DHCP Lease object. This method specifies the host name that the DHCP client sends to the Infoblox appliance using DHCP option 12.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get client_hostname
my $client_hostname = $lease->client_hostname();
```

cltt( )

Use this method to retrieve the CLTT (Client Last Transaction Time) value of a DHCP Lease object. This method specifies the time of the last transaction with the DHCP client for this lease.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get cltt
my $cltt = $lease->cltt();
```

discovered_data( )

Use this method to retrieve the discovered data of a DHCP Lease object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Data object.

Example

```
#Get discovered_data value
my $discovered_data = $object->discovered_data();
```

discovered_duid( )

Use this method to retrieve the discovered DHCPv6 UID (DUID) of a DHCP Lease object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_duid
my $discovered_duid = $bindptr->discovered_duid();
```

discovered_name( )

Use this method to retrieve the discovered name of a DHCP Lease object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
my $discovered_name = $lease->discovered_name();
```

discoverer( )

Use this method to retrieve the discoverer of a DHCP Lease object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $lease->discoverer();
```

ends( )

Use this method to retrieve the end time value of a DHCP Lease object. This method specifies the day, date, and time that a lease ended.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get ends
my $ends = $lease->ends();
```

fingerprint( )

Use this method to retrieve the descripiton of the DHCP fingerprint of a DHCP Lease object. This is a read-only attribute.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get fingerprint
my $fingerprint = $lease->fingerprint();
```

first_discovered( )

Use this method to retrieve the date and time when the DHCP Lease object was first discovered.

Parameter

none

Returns

The method returns the date and time when the DHCP Lease object was first discovered.

Example

```
#Get first_discovered
my $first_discovered = $lease->first_discovered();
```

hardware( )

Use this method to retrieve the hardware type of a DHCP Lease object. This method specifies the MAC address of the network interface on which the lease will be used. This method is for IPv4 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get hardware
my $hardware = $lease->hardware();
```

ip_address( )

Use this method to retrieve the IPv4 or IPv6 address that the Infoblox appliance leased to the DHCP client. Use this method, in place of the `ipv4addr()` method, even for IPv4 addresses.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get ip_address
my $ip_address = $lease->ip_address();
```

ipv4addr( )

Use this method to retrieve the IP address that the Infoblox appliance leased to the DHCP client. This method is being deprecated in favor of the `ip_address()` method. This method is for IPv4 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $lease->ipv4addr();
```

ipv6_duid( )

Use this method to retrieve the DUID value of an IPv6 address that the Infoblox appliance leased to the DHCP client. This method is for IPv6 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get ipv6_duid
my $ipv6_duid = $lease->ipv6_duid();
```

ipv6_iaid( )

Use this method to retrieve the Interface ID value of an IPv6 address that the Infoblox appliance leased to the DHCP client. This method is for IPv6 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get ipv6_iaid
my $ipv6_iaid = $lease->ipv6_iaid();
```

ipv6_preferred_lifetime( )

Use this method to retrieve the preferred lifetime value of an IPv6 address that the Infoblox appliance leased to the DHCP client. This method is for IPv6 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get ipv6_preferred_lifetime
my $ipv6_preferred_lifetime = $lease->ipv6_preferred_lifetime();
```

ipv6_prefix_bits( )

Use this method to retrieve the prefix bits value of an IPv6 address that the Infoblox appliance leased to the DHCP client. This method is for IPv6 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get ipv6_prefix_bits
my $ipv6_prefix_bits = $lease->ipv6_prefix_bits();
```

is_invalid_mac( )

Use this method to retrieve the flag used to indicate whether an invalid MAC address is used. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get is_invalid_mac value
my $is_invalid_mac = $lease->is_invalid_mac();
```

last_discovered( )

Use this method to retrieve the time when this object was last discovered.

The default value for this field is empty.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get last_discovered
my $last_discovered = $lease->last_discovered();
```

mac( )

Use this method to retrieve the MAC address of the DHCP client that leased the IP address. This method is for IPv4 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get mac
my $mac = $lease->mac();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $lease->ms_ad_user_data();
```

network( )

Use this method to find the network associated with this lease. This property is read-only.

Parameter

N/A

Returns

The method returns the network associated with the lease in the string of the form "network/netmask".

Example

```
#Get network property of the lease
my $network = $lease->network();
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $lease->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the network device IP address.

Example

```
#Get network_component_ip
my $network_component_ip = $lease->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the network device name.

Example

```
#Get network_component_name
my $network_component_name = $lease->network_component_name();
```

network_component_port_description( )

Use this method to retrieve the description of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the description of the network device port.

Example

```
#Get network_component_port_description
my $network_component_port_description = $lease->network_component_port_description();
```

network_component_port_name( )

Use this method to retrieve the name of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the name of the port on the network device.

Example

```
#Get network_component_port_name
my $network_component_port_name = $lease->network_component_port_name();
```

network_component_port_number( )

Use this method to retrieve the number of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the network device port number.

Example

```
#Get network_component_port_number
my $network_component_port_number = $lease->network_component_port_number();
```

network_component_type( )

Use this method to retrieve the type of the network device that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the network device type.

Example

```
#Get network_component_type
my $network_component_type = $lease->network_component_type();
```

network_view( )

Use this method to retrieve the network view of the DHCP lease.

Parameter

N/A

Returns

This method returns the network view of the DHCP lease as Infoblox::DHCP::View object.

Example

```
#Get network view
my $nview = $lease->network_view();
```

netbios( )

Use this method to retrieve the name in the NetBIOS reply that responded to a NetBIOS query.

Returns

The method returns the attribute value.

Example

```
#Get netbios
```

```
my $netbios = $lease->netbios();
```

next_binding_state( )

Use this method to retrieve the subsequent binding state when the current lease expires. This method is for IPv4 leases only.

```
 Free      : The lease is available for clients to use.
 Active    : The lease is currently in use by a DHCP client.
 Expired   : The lease was in use, but the DHCP client never renewed it, so it is no longer valid.
 Released  : The DHCP client returned the lease to the appliance.
 Abandoned: The Infoblox appliance cannot lease this IP address because the appliance received a response
when it pinged the address.
```

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get next_binding_state
my $next_binding_state = $lease->next_binding_state();
```

on_commit( )

Use this method to retrieve the list of commands to be executed upon the granting of the lease.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get on_commit
my $on_commit = $lease->on_commit();
```

on_expiry( )

Use this method to retrieve the list of commands to be executed upon the expiration of the lease.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get on_expiry
my $on_expiry = $lease->on_expiry();
```

on_release( )

Use this method to retrieve the list of commands to be executed upon the release of the lease.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get on_release
my $on_release = $lease->on_release();
```

option( )

Use this method to retrieve the option value of a DHCP Lease object. This method specifies the agent circuit ID and remote ID sent by a DHCP relay agent in DHCP option 82. This method is for IPv4 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get option
my $option = $lease->option();
```

os( )

Use this method to retrieve the operating system associated with this DHCP lease.

Returns

The method returns the attribute value.

Example

```
#Get os
my $os = $lease->os();
```

port_duplex( )

Use this method to retrieve the duplex setting of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the duplex setting of the network device port. The returend value, if any, is one of the following:

```
Full
Half
```

Example

```
#Get port_duplex
my $port_duplex = $lease->port_duplex();
```

port_link_status( )

The method returns the link status of the network device port. The returned value, if any, is one of the following:

Parameter

none

Returns

The method returns the port link status. Returned values, if any, are one of the following:

```
Connected
Not Connected
Unknown
```

Example

```
#Get port_link_status
my $port_link_status = $lease->port_link_status();
```

port_speed( )

Use this method to retrieve the speed of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the speed value of the network device port. The returned value, if any, is one of the following:

```
10M
100M
1G
10G
100G
Unknown
```

Example

```
#Get port_speed
my $port_speed = $lease->port_speed();
```

port_status( )

Use this method to retrieve the status of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the status of the network device port. The returned value, if any, is one of the following:

```
Up
Down
Unknown
```

Example

```
#Get port_status
my $port_status = $lease->port_status();
```

port_vlan_description( )

Use this method to retrieve the VLAN description of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the VLAN description of the network device port.

Example

```
#Get port_vlan_description
my $port_vlan_description = $lease->port_vlan_description();
```

port_vlan_name( )

Use this method to retrieve the VLAN name of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the VLAN name of the network device port.

Example

```
#Get port_vlan_name
my $port_vlan_name = $lease->port_vlan_name();
```

port_vlan_number( )

Use this method to retrieve the VLAN number of the network device port that is connected to the DHCP Lease object.

Parameter

none

Returns

The method returns the VLAN number of the network device port.

Example

```
#Get port_vlan_number
my $port_vlan_number = $lease->port_vlan_number();
```

protocol( )

Use this method to determine whether the IP address the Infoblox appliance leased an IPv4 or IPv6 address to the client.

Parameter

N/A

Returns

The method returns the attribute value ('IPV4' or 'IPV6').

Example

```
#Get protocol
my $protocol = $lease->protocol();
```

remote_id( )

Use this method to retrieve an agent remote ID (option 82 sub-option). This is a read-only attribute.

Remote ID can be presented either in the ASCII form (e.g. "abcd") or in the form of colon separated HEX values (e.g. 1:2:ab:cd). HEX representation is only used when sub-option value contains unprintable characters. If a remode ID sub-option value is an ASCII string, it's always enclosed in quotes to prevent ambiguous values (e.g. "10:20" - ASCII 5 byte string; 10:20 - HEX 2 byte value). Remote ID can be in ASCII form (e.g. ""abcd"") or in colon-separated HEX form (e.g. "1:2:ab:cd").

```
 ASCII: ASCII representation is used if the remote ID sub-option contains only printable ASCII charaters
(ASCII characters in range "x20-0x7E").
        - The backslash symbol (\) is used as an escape symbol to escape the quote symbol (") in an ASCII
string.
        - Double backslashes (\\) are used to represent the backslash symbol (\) in an ASCII string.
 HEX  : HEX representation is used only when the remote ID sub-option value contains unprintable characters
and is normalized as follows:
        - starting zero is removed from digits: 1, a - Valid, 01, 0a - Invalid;
        - lowercase characters are used for symbols: fa - Valid, FA - Invalid.
```

NIOS does not support the convertion between HEX and ASCII formats. Searches are performed using the exact same format and value as the sub-option is represented.

Query examples assume the following leases are stored in the database:

```
 Number  : option field                                                                  : extracted remote_id field
 Lease01 : agent.remote-id="00152654358700" agent.circuit-id="BX1-PORT-003" : "00152654358700"
 Lease02 : agent.remote-id="Dhcp Relay 10" agent.circuit-id="Port008"       : "Dhcp Relay 10"
 Lease03 : agent.remote-id="00:01:02"                                                : "00:01:02"
 Lease04 : agent.remote-id=0:1:2                                                     : 0:1:2
 Lease05 : agent.remote-id=02:03                                                     : 2:3
 Lease06 : agent.remote-id=10:20                                                     : 10:20
 Lease07 : agent.circuit-id="no-remote-id"                                           :
```

Expected results:

```
 Query                    : Returned leases                                          : Comments
 remote_id=01:02          : None                                                     : EXACT query. No results
are expected
 remote_id="Dhcp Relay 10" : Lease02                                                 : EXACT query for an
ASCII value.
 remote_id=0:1:2          : Lease04                                                  : EXACT query for a HEX
value.
 remote_id=00:01:02       : None                                                     : EXACT query for a HEX
value. No results are expected as the search value is not normalized to the same format used in the
database.
 remote_id~=10            : Lease02, Lease06                                         : REGEX query.
 remote_id~=^".*1         : Lease01, Lease02, Lease03                                : REGEX query. Only ASCII
values are expected due to the starting quote (") in the search value.
 remote_id~=^[^"]*2       : Lease04, Lease05, Lease06                                : REGEX query. Only HEX
values are expected as the starting quote (") is excluded from the search value.
 remote_id=""             : None                                                     : EXACT query. No results
are expected as no leases that contain an empty remote ID value exist in the database.
 remote_id~=""            : Lease01, Lease02, Lease03, Lease04, Lease05, Lease06 : REGEX query. This query
is expected to match any lease that contains remote ID set to any value.
```

NOTE: EXACT queries (without the ~ symbol) are perfomed using the get method. REGEX queries (with the ~ symbol) are perfomed using the search method.

NOTE: Lease07 is not expected to be returned when searching for the remote ID sub-option.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get remote_id
my $remote_id = $lease->remote_id();
```

starts( )

Use this method to retrieve the start time value of a DHCP Lease object. This method specifies the day, date, and time that the lease started.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get starts
my $starts = $lease->starts();
```

tsfp( )

Use this method to retrieve the TSFP (Time Sent From Partner) value of a DHCP Lease object. This method specifies the time that the current lease state ends, from the point of view of a remote DHCP failover peer. This method is for IPv4 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get tsfp
my $tsfp = $lease->tsfp();
```

tstp( )

Use this method to retrieve the TSTP (Time Sent To Partner) value of a DHCP Lease object. This method specifies the time that the current lease state ends, from the point of view of a local DHCP failover peer. This method is for IPv4 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get tstp
my $tstp = $lease->tstp();
```

uid( )

Use this method to retrieve the UID (User ID) value of a DHCP Lease object. This method specifies the client identifier that the DHCP client sends the Infoblox appliance (in DHCP option 61) when it acquires the lease. Not all DHCP clients send a UID. This method is for IPv4 leases only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get uid
my $uid = $lease->uid();
```

username( )

Use this method to retrieve the user name that the server has associated with a DHCP Lease object.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get username
my $username = $lease->username();
```

served_by( )

Use this method to retrieve the IP address of the server that hands out an active lease to a client.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get served_by
my $served_by = $lease->served_by();
```

variable( )

Use this method to retrieve the variable value of a DHCP Lease object. This method keeps all variables related to the DDNS update of the DHCP lease. The variables can be one of the following:

```
 ddns-text        : The ddns-text variable is used to record the value of the client's TXT identification
record when the
                   interim DDNS update style has been used to update the DNS service for a particular
lease.

 ddns-fwd-name    : The ddns-fwd-name variable records the value of the name used when the client's A
record was updated, if a DDNS
                   update was successfully completed by the server. The server may have used this name
when it updated the
                   client's PTR record as well.

 ddns-client-fqdn : If the server is configured to use the interim DDNS update style, and is also
configured to allow clients
                   to update their own FQDNs, and the client did in fact update its own FQDN, then the
ddns-client-fqdn
                   variable records the name that the client indicated it used. This is also the name that
the server
                   used to update the client's PTR record in this case.

 ddns-rev-name    : If the server successfully updates the client's PTR record, this variable will record
the name that the
                   DHCP server used for the PTR record. The name to which the PTR record points will be
either the
                   ddns-fwd-name or the ddns-client-fqdn.
```

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get variable
```

```
my $variable = $lease->variable();
```

v_cluster( )

Use this method to retrieve the name of the VMware cluster associated with the DHCP Lease object. This method is read-only. This method is for IPv4 leases only.

Parameter

none

Returns

This method returns a string that contains the VMware cluster name. The default value is an empty string.

Example

```
#Get v_cluster
my $v_cluster = $lease->v_cluster();
```

v_datacenter( )

Use this method to retrieve the name of the VMware datacenter associated with the DHCP Lease object. This method is read-only. This method is for IPv4 leases only.

Parameter

none

Returns

This method returns a string that contains the VMware datacenter name. The default value is an empty string.

Example

```
#Get v_datacenter
my $v_datacenter = $lease->v_datacenter();
```

v_host( )

Use this method to retrieve the name of the VMware host associated with the DHCP Lease object. This method is read-only. This method is for IPv4 leases only.

Parameter

none

Returns

This method returns a string that contains the VMware host name. The default value is an empty string.

Example

```
#Get v_host
my $v_host = $lease->v_host();
```

v_name( )

Use this method to retrieve the name of the VMware entity associated with the DHCP Lease object. This method is read-only. This method is for IPv4 leases only.

Parameter

none

Returns

This method returns a string that contains the VMware entity name. The default value is an empty string.

Example

```
#Get v_name
my $v_name = $lease->v_name();
```

v_netadapter( )

Use this method to retrieve the name of the physical network adapter through which the VMware entity is connected to the appliance. This

method is read-only. This method is for IPv4 leases ohly.

Parameter

none

Returns

This method returns a string that contains the network adapter name. The default value is an empty string.

Example

```
#Get v_netadapter
my $v_netadapter = $lease->v_netadapter();
```

v_switch( )

Use this method to retrieve the name of the virtual switch through which the VMware entity is connected to the appliance. This method is read-only. This method is for IPv4 leases only.

Parameter

none

Returns

This method returns a string that contains the virtual switch name. The default value is an empty string.

Example

```
#Get v_switch
my $v_switch = $lease->v_switch();
```

v_type( )

Use this method to retrieve the type of VMware entity associated with the DHCP Lease object. This method is read-only. This method is for IPv4 leases only.

Parameter

none

Returns

This method returns a string that contains the VMware entity name. The default value is an empty string. The returned value, if any, can be one of the following:

```
VirtualMachine
HostSystem
VirtualCenter
```

Example

```
#Get v_type
my $v_type = $lease->v_type();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP Lease object, such as get, search, and remove. Also, this sample code includes error handling for the operations.

#Preparation prior to DHCP Lease operations

```
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $host_ip   = "192.168.1.2";
my $host_name = "infoblox.localdomain";
my $session = Infoblox::Session->new(
    master   => $host_ip,       #appliance host ip
    username => "admin",        #appliance user login
    password => "infoblox"      #appliance password
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
```

```
}
print "Session created successfully.\n";

#Create a member object
 my $member = Infoblox::DHCP::Member->new(
    name     => $host_name,
    ipv4addr => $host_ip,
);

unless($member) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create a network object
my $network = Infoblox::DHCP::Network->new(
                            network  => "10.0.0.0/8",
                            comment  => "add network",
                            members  => [$member]
                            );
unless($network){
       die("Construct network object fail: ",
               Infoblox::status_code(). ":" .Infoblox::status_detail());
       }

print"Network object created successfully.\n";

#Verify if the network exists
my $object = $session->get(
               object  => "Infoblox::DHCP::Network",
               network => "10.0.0.0/8"
               );
unless($object){
       print"Network does not exist on server, safe to add the network.\n";
       $session->add($network)
               or die("Add network failed: ",
                       $session->status_code(). ":" .$session->status_detail());
       }

print"Network added successfully.\n";

#Create a dhcp range object
my $dhcp_range = Infoblox::DHCP::Range->new(
    network    => "10.0.0.0/8",
    start_addr => "10.0.0.1",
    end_addr   => "10.0.0.10",
    member     => $member,
);

unless($dhcp_range){
       die("Construct dhcp range object failed: ",
               Infoblox::status_code(). ":" .Infoblox::status_detail());
       }

print "dhcp range object created successfully.\n";

#Add the dhcp range to the Infoblox appliance
$session->add($dhcp_range)
               or die("Add dhcp range failed: ",
                       $session->status_code(). ":" .$session->status_detail());

print "dhcp range added successfully.\n";

my $result = $session->import_data(
       "type" => "leases",
       "path"=> "./API_unit_test_sample_code/import_dhcpd.lease",
       "format" => "ISC",
       "lease_precedence" => "replace-previous"
      );

unless($result){
        die("Import lease failed: ",
          $session->status_code() . ":" . $session->status_detail());
 }

print "Import dhcp lease successfull.\n";
```

#Search for a DHCP Lease object

```
my @retrieved_objs= $session->search(
                    object   => "Infoblox::DHCP::Lease" ,
                    ipv4addr => '^10\..*'
                    );
my $desired_lease = $retrieved_objs[0];
unless($desired_lease){
        die("search lease failed: ",
          $session->status_code() . ":" . $session->status_detail());
 }

print "Search dhcp lease object found at least 1 matching entry\n";
```

#Get a DHCP Lease object

```
#Get a DHCP lease by IP address.
my @retrieved_objs = $session->get(
                         object   => "Infoblox::DHCP::Lease",
                         ipv4addr => "10.0.0.10"
                         );
my $desired_lease = $retrieved_objs[0];
unless($desired_lease){
        die("get lease failed: ",
          $session->status_code() . ":" . $session->status_detail());
 }

print "Get dhcp lease object found at least 1 matching entry\n";
```

#Remove a DHCP Lease object

```
#Submit the object for removal
$session->remove($desired_lease)
    or die("Remove dhcp lease failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "dhcp lease object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::MAC - DHCP MAC object.

DESCRIPTION

A MAC Address is a unique hardware identifier. The Infoblox device can filter address requests by the MAC address of a requesting hosts. The filter instructs the Infoblox device either to grant or deny an address request if the requesting host matches the filter. Also, it is possible configure specific MAC addresses within a filter to expire after a certain amount of time has passed.

CONSTRUCTOR

```
 my $mac = Infoblox::DHCP::MAC->new(
       filter                => $string,        #Required
       mac                   => $mac_addr,      #Required
       authentication_time   => $num,           #Optional / Default is empty
       comment               => $string,        #Optional / Default is empty
       expiration_time       => $num,           #Optional / Default is 0 for never expire
       extattrs              => { $string => $extattr, ... },      #Optional / Default is undefined
       extensible_attributes => { $string => $string | $num, $string => [ $string | $num, ... ], ... },
#Optional / Default is undefined
       guest_custom_field1   => $string,        #Optional / Default is empty
       guest_custom_field2   => $string,        #Optional / Default is empty
       guest_custom_field3   => $string,        #Optional / Default is empty
       guest_custom_field4   => $string,        #Optional / Default is empty
       guest_email           => $string,        #Optional / Default is empty
       guest_first_name      => $string,        #Optional / Default is empty
       guest_last_name       => $string,        #Optional / Default is empty
       guest_middle_name     => $string,        #Optional / Default is empty
       guest_phone           => $string,        #Optional / Default is empty
       is_registered_user    => "true" | "false", #Optional / Default is "true"
       reserved_for_infoblox => $string,        #Optional / Default is "false"
```

```
        username              => $string,        #Optional / Default is empty
);
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DHCP MAC object.

Infoblox::Session->add( )

Use this method to add a DHCP MAC object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct a DHCP MAC object
my $mac = Infoblox::DHCP::MAC->new(
            "mac"                  => "00:00:00:00:00:03",
            "filter"               => "new",
            "comment"              => "dhcp mac object",
            "expiration_time"      => "0",
            "username"             => "infoblox_user",
            "authentication_time"  => "0",
            "reserved_for_infoblox" => "For Infoblox Use only",
);
#Submit for addition
my $response = $session->add($mac)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP MAC object:

 mac    - Optional. MAC address of the DHCP MAC object.
 filter - Optional. MAC filter name.
 comment  - Optional. A comment in string format.
 username - Optional. Username of the DHCP MAC object.
 fingerprint - Optional. DHCP fingerprint description.
 extattrs - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
#Get DHCP MAC object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::MAC",
    mac    => "00:00:00:00:00:03",
    filter => "new",
);

# get all objects with a given extensible attribute
my @retrieved_objs = $session->get(
    object               => "Infoblox::DHCP::MAC",
    extensible_attributes => { 'Site' => 'Santa Clara' }
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP MAC object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the expiration time.
$mac->expiration_time("1234567890");
#Submit modification
my $response = $session->modify( $mac );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP MAC object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP MAC object, and then submit this object for removal.

Example

```
#Get DHCP MAC object through the session
my @retrieved_objs = $session->get(
    object     => "Infoblox::DHCP::MAC",
    mac        => "00:00:00:00:00:03",
    filter     => "new",
);
#Find the desired object from the retrieved list.
my $desired_mac = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_mac );
```

Infoblox::Session->search( )

Use this method to search for DHCP MAC objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific DHCP MAC Address object:

 comment  - Optional. A comment in string format (regular expression).
 mac      - Optional. MAC address of the DHCP MAC object (regular expression).
 username - Optional. Username of the DHCP MAC object (regular expression).
 filter   - Optional. MAC address filter name (regular expression).
 fingerprint - Optional. DHCP fingerprint description (regular expression).
 extattrs - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all DHCP MAC objects that are specified in the "new" MAC filter.
my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::MAC",
    mac    => "00:00:00:00:00.*",
    filter => "new"
);

# search all DHCP MAC associations with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
   object => "Infoblox::DHCP::MAC",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DHCP MAC object.

authentication_time( )

Use this method to set or retrieve the authentication time. Indicates the time when the MAC address was first authenticated.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The absolute UNIX time (seconds since UNIX epoch) when the address was authenticated. The maximum value can extend upto 4294967295.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get authentication_time
my $authentication_time = $mac->authentication_time();
#Modify authentication_time
$mac->authentication_time("1234567890");
```

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $mac->comment();
#Modify comment
$mac->comment("Modified DHCP MAC comment");
```

expired( )

Use this method to retrieve the expired flag of the DHCP MAC object .

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get expired
my $expired = $mac->expired();
```

expiration_time( )

Use this method to set or retrieve the expiration time of the DHCP MAC object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

By default, the MAC address never expires; otherwise, it is the absolute UNIX time (seconds since UNIX epoch) when the address expires. The maximum value can extend upto 4294967295.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get expiration_time
my $expiration_time = $mac->expiration_time();
#Modify expiration_time
$mac->expiration_time("1234567890");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP MAC object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $mac->extattrs();
#Modify extattrs
$mac->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP MAC object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $mac->extensible_attributes();
#Modify extensible attributes
$mac->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

fingerprint( )

Use this method to retrieve the description of the DHCP fingerprint of a DHCP MAC object. This is a read-only attribute.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get fingerprint
my $fingerprint = $mac->fingerprint();
```

guest_custom_field1 ( )

Use this method to set or retrieve the value in Custom Field 1 of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field1
my $guest_custom_field1 = $dhcp->guest_custom_field1();
#Modifying guest_custom_field1
$dhcp->guest_custom_field1('Custom value 1');
```

guest_custom_field2 ( )

Use this method to set or retrieve the value in Custom Field 2 of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field2
my $guest_custom_field2 = $dhcp->guest_custom_field2();
#Modifying guest_custom_field2
$dhcp->guest_custom_field2('Custom value 2');
```

guest_custom_field3 ( )

Use this method to set or retrieve the value in Custom Field 3 of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field3
my $guest_custom_field3 = $dhcp->guest_custom_field3();
#Modifying guest_custom_field3
$dhcp->guest_custom_field3('Custom value 3');
```

guest_custom_field4 ( )

Use this method to set or retrieve the value in Custom Field 4 of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_custom_field4
my $guest_custom_field4 = $dhcp->guest_custom_field4();
#Modifying guest_custom_field4
$dhcp->guest_custom_field4('Custom value 4');
```

guest_email ( )

Use this method to set or retrieve the email address in the Email field of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 128 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_email
my $guest_email = $dhcp->guest_email();
#Modifying guest_email
$dhcp->guest_email('user@domain.com');
```

guest_first_name ( )

Use this method to set or retrieve the entry in the First Name field of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_first_name
my $guest_first_name = $dhcp->guest_first_name();
#Modifying guest_first_name
$dhcp->guest_first_name('John');
```

guest_last_name ( )

Use this method to set or retrieve the entry in the Last Name field of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_last_name
my $guest_last_name = $dhcp->guest_last_name();
#Modifying guest_last_name
$dhcp->guest_last_name('Doe');
```

guest_middle_name ( )

Use this method to set or retrieve the entry in the Middle Name field of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_middle_name
my $guest_middle_name = $dhcp->guest_middle_name();
#Modifying guest_middle_name
$dhcp->guest_middle_name('Robert');
```

guest_phone ( )

Use this method to set or retrieve the entry in the Phone field of the guest registration page of this DHCP MAC object.

Parameter

The valid value is a string. The default value is undefined. The maximum length is 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting guest_phone
my $guest_phone = $dhcp->guest_phone();
#Modifying guest_phone
$dhcp->guest_phone('1-555-555-5555');
```

filter( )

Use this method to set or retrieve the filter value of the DHCP MAC object .

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the DHCP MAC filter. Maximum length upto 1024 bytes is supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get filter
my $filter = $mac->filter();
#Modify filter
$mac->filter("filter1");
```

mac( )

Use this method to set or retrieve the MAC address of the DHCP MAC object .

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

MAC Address of the DHCP MAC object. Format for the hexadecimal strings for MAC addresses and vendor prefixes with colons or dashes. Both of the following formats are acceptable: 11:11:11:11:11:11 and 11-11-11-11-11-11.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mac
my $mac_value = $mac->mac();
#Modify mac
$mac->mac("00:00:00:11:11:11");
```

is_registered_user( )

Use this method to set or retrieve the is_registered_user flag of the DHCP MAC object. If this flag is "false", then this DHCP MAC object represents a "Guest" registration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the is_registered_user flag or "false" to deactivate/unset it. The default value for this field is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get is_registered_user
my $is_registered_user = $mac->is_registered_user()
# Modify is_registered_user
$mac->is_registered_user("true");
```

reserved_for_infoblox( )

Set this flag to reserve the MAC address for an Infoblox appliance.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Reserved to write comment related to this particular MAC address. Comment cannot exceed 1024 bytes long.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get reserved_for_infoblox
my $reserved_for_infoblox = $mac->reserved_for_infoblox();
#Modify reserved_for_infoblox
$mac->reserved_for_infoblox("reserved for Infoblox");
```

username( )

Use this method to set or retrieve the user name of the DHCP MAC object .

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

User name of the DHCP MAC object. Used for authenticated DHCP purposes. Maximum of 128 characters supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get username
my $username = $mac->username();
#Modify username
$mac->username("user_infoblox");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP MAC object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a DHCP MAC Filter object
my $macfilter = Infoblox::DHCP::Filter::MAC->new ( "name" => "mac_filter");

unless($macfilter) {
     die("Construct mac filter failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "MAC Filter object created successfully\n";

#Verify if the DHCP MAC Filter exists in the Infoblox appliance
my $object = $session->get(object => "Infoblox::DHCP::Filter::MAC", name => "mac_filter");
unless ($object) {
   print "mac filter does not exist on server, safe to add the mac filter\n";
   $session->add($macfilter)
      or die
```

```
            ("Add mac filter failed: ",
             $session->status_code() . ":" . $session->status_detail());
}
print "DHCP MAC Filter added successfully\n";
```

#Create a DHCP MAC object

```
my $mac = Infoblox::DHCP::MAC->new(
          "mac"                  => "00:00:00:00:00:01",
          "filter"               => "mac_filter",
          "comment"              => "dhcp mac object",
          "expiration_time"      => "0",
          "username"             => "infoblox_user",
          "authentication_time"  => "0",
          "reserved_for_infoblox" => "For Infoblox Use only",
);

unless($mac) {
          die("Construct MAC object failed: ",
                Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "MAC Address object created successfully\n";

#Add the MAC Address object into the Infoblox appliance through a session
$session->add($mac)
     or die("Add MAC Address object failed: ",
          $session->status_code() . ":" . $session->status_detail());
print "DHCP MAC Address object added successfully\n";
```

#Search for a specific DHCP MAC Address object

```
#Search for all DHCP MAC address objects
my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::MAC",
    filter => "mac_filter" );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search for MAC Address object failed: ",
              $session->status_code() . ":" . $session->status_detail());
}
print "Search MAC Address object found at least 1 matching entry\n";
```

#Get and modify a MAC Address object

```
#Get MAC Address object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::MAC",
    mac    => "00:00:00:00:00:01",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get MAC Address object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get MAC Address object found at least 1 matching entry\n";

#Modify one of the attributes of the obtained MAC Address object
$object->expiration_time("1234567890");

#Apply the changes
$session->modify($object)
    or die("Modify MAC Address object failed: ",
          $session->status_code() . ":" . $session->status_detail());
print "MAC Address object modified successfully \n";
```

#Remove a MAC Address object

```
#Get MAC Address object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::MAC",
    mac    => "00:00:00:00:00:01",
    filter => "mac_filter",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get MAC Address object failed: ",
```

```
        $session->status_code() . ":" . $session->status_detail());
}
print "Get MAC Address object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove MAC Address object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "MAC Address object removed successfully \n";

#Submit the MAC Address Filter object for removal
$session->remove($macfilter)
    or die("Remove MAC Address Filter object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "MAC Address Filter object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::Member - DHCP Member object.

DESCRIPTION

A grid member is part of a grid which is a group of two or more Infoblox appliances that share sections of a common, distributed, built-in database. A grid member inherits its settings from the grid. A member is a single Infoblox appliance or an HA pair that provides DHCP services seamlessly across an entire network.

CONSTRUCTOR

```
my $member = Infoblox::DHCP::Member->new(
    ipv4addr => $ipv4addr, #Optional. At least one ipv4addr or ipv6addr is required.
    ipv6addr => $ipv6addr, #Optional. At least one ipv4addr or ipv6addr is required.
    name     => $fqdn,     #Optional
);
```

MODULE METHODS

This section describes all the functions that you can apply to an DHCP Member object.

Infoblox::DHCP::Network->members( )

Use this function to specify the primary member for a network. See Infoblox::DHCP::Network->members() for parameters and return values.

Example

```
my $member1 = Infoblox::DHCP::Member->new(
    name     => "localhost.localdomain",
    ipv4addr => "192.168.1.2",
);

unless($member1) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create the Network object with this member
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/255.0.0.0",
    members => [$member1],
);
```

Infoblox::DHCP::Range->member( )

Use this function to specify the primary member for a DHCP range. See Infoblox::DHCP::Range->members() for parameters and return values.

Example

```
my $member = Infoblox::DHCP::Member->new(
    name     => "localhost.localdomain",
    ipv4addr => "192.168.1.2",
);

unless($member) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create the DHCP Range object with this member
my $dhcp_range = Infoblox::DHCP::Range->new(
    network    => "10.0.0.0/8",
    start_addr => "10.0.0.1",
    end_addr   => "10.0.0.10",
    member     => $member,
);
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DHCP Member object.

ipv4addr( )

Use this method to set or retrieve the IPv4 address of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IPv4 address (32 bits) of the member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $member->ipv4addr();
#Modify ipv4addr
$member->ipv4addr("192.168.1.3");
```

ipv6addr( )

Use this method to set or retrieve the IPv6 address of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IPv6 address of the member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6addr
my $ipv6addr = $member->ipv6addr();
#Modify ipv6addr
$member->ipv6addr("fd46:e105:2eac:89b1::1");
```

name( )

Use this method to set or retrieve the name of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A host name can have a maximum of 256 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $member->name();
#Modify name
$member->name("dhcp.infoblox.com");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP Member object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP Member object

```
my $member1 = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
);

unless($member1) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create the Network object with this member
my $network = Infoblox::DHCP::Network->new(
                    network => "10.0.0.0/255.0.0.0",
                    comment => "add network",
                    members => [ $member1 ]
);

unless($network) {
            die("Construct Network object failed: ",
                  Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network object created successfully\n";

#Add the Network object into the Infoblox appliance through a session
$session->add($network)
     or die("Add Network object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "DHCP member object added to the network successfully\n";

####PROGRAM ENDS####
```

NAME

Infoblox::DHCP::MSOption - Microsoft (r) Server DHCP Option object.

DESCRIPTION

DHCP options describe network configuration settings and various services available on the network. These options occur as variable-length fields at the end of DHCP messages.

You can add or change only DHCP options that are in the Microsoft server and NIOS predefined list of options. Options that are not common to both are read-only.

Following are the options that the Microsoft server and the NIOS predefined list of options have in common:

```
 code     name
 ============================================================
   2     'Time Offset'
   4     'Time Server'
   5     'Name Servers'
   7     'Log Servers'
   8     'Cookie Servers'
   9     'LPR Servers'
   10    'Impress Servers'
   11    'Resource Location Servers'
   12    'Host Name'
   13    'Boot File Size'
   14    'Merit Dump File'
   16    'Swap Server'
   17    'Root Path'
   18    'Extensions Path'
   19    'IP Layer Forwarding'
   20    'Nonlocal Source Routing'
   21    'Policy Filter Masks'
   22    'Max DG Reassembly Size'
   23    'Default IP Time-to-live'
   24    'Path MTU Aging Timeout'
   25    'Path MTU Plateau Table'
   26    'MTU Option'
   27    'All subnets are local'
   29    'Perform Mask Discovery'
   30    'Mask Supplier Option'
   31    'Perform Router Discovery'
   32    'Router Solicitation Address'
   33    'Static Route Option'
   34    'Trailer Encapsulation'
   35    'ARP Cache Timeout'
   36    'Ethernet Encapsulation'
   37    'TCP Default Time-to-live'
   38    'Keepalive Interval'
   39    'Keepalive Garbage'
   40    'NIS Domain Name'
   41    'NIS Servers'
   42    'NTP Servers'
   43    'Vendor Specific Info'
   44    'WINS/NBNS Servers'
   45    'NetBIOS over TCP/IP NBDD'
   46    'WINS/NBT Node Type'
   47    'NetBIOS Scope ID'
   48    'X Window System Font'
   49    'X Window System Display'
   64    'NIS+ Domain Name'
   65    'NIS+ Servers'
```

```
   66    'Boot Server Host Name'
   67    'Bootfile Name'
   68    'Mobile IP Home Agents'
   69    'Simple Mail Transport Protocol (SMTP) Servers'
   70    'Post Office Protocol (POP3) Servers'
   71    'Network News Transport Protocol (NNTP) Servers'
   72    'World Wide Web (WWW) Servers'
   73    'Finger Servers'
   74    'Internet Relay Chat (IRC) Servers'
   75    'StreetTalk Servers'
   76    'StreetTalk Directory Assistance (STDA) Servers'
```

CONSTRUCTOR

```
  my $option = Infoblox::DHCP::MSOption->new(
     code         => $int,                              #Required
     value        => $num | $string |"true"|"false",    #Required
     name         => $string,                           #Optional
     type         => $string,                           #Optional
     vendor_class => $string,                           #Optional / If not specified, it uses the default
Microsoft vendor class
     user_class   => $string,                           #Optional / If not specified, it uses the default
Microsoft user class
   );
```

MODULE METHODS

The following functions can be applied to a DHCP Option object.

Infoblox::Grid::MSServer::DHCP->ms_options( )

Use this function to specify DHCP options at the Microsoft server level. See Infoblox::Grid::MSServer::DHCP->ms_options() for parameters and return values.

Example

```
       #Construct a DHCP Option object
       my $opt1 = Infoblox::DHCP::MSOption->new(
                                              name         => 'Time Offset',
                                              code         => 2,
                                              type         => 'long',
                                              value        => 50,
                                              vendor_class => 'DHCP Standard Options',
                                              user_class   => 'Default User Class',
                                             );
       # Configure a DHCP option for a Microsoft DHCP server
       my $response = $MSServer_DHCP->ms_options([$opt1]);
```

Infoblox::DHCP::Range->ms_options( )

Use this function to specify Microsoft DHCP options at the range level. See Infoblox::DHCP::Range->ms_options() for parameters and return values.

Example

```
       my $opt1 = Infoblox::DHCP::MSOption->new(
                                              name         => 'LPR Servers',
                                              code         => 9,
                                              type         => 'array of ip address',
                                              value        => '10.4.1.0,10.4.1.1,10.4.1.2',
                                              vendor_class => 'DHCP Standard Options',
                                              user_class   => 'Default User Class',
                                             );
       # Configure a Microsoft DHCP option for a range
       my $response = $Range->ms_options([$opt1]);
```

Infoblox::DHCP::FixedAddr->ms_options( )

Use this function to specify DHCP options at the fixed address level. See Infoblox::DHCP::FixedAddr->ms_options() for parameters and return values.

Example

```
       my $opt1 = Infoblox::DHCP::MSOption->new(
                                              name         => 'Static Route Option',
                                              code         => 33,
```

```
                                                type          => 'array of ip address pair',
                                                value         => '10.5.1.0 10.5.1.1,10.5.1.2 10.5.1.3',
                                               );
    # Configure a DHCP option for a network
    my $response = $FixedAddr->ms_options([$opt1]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP option.

name( )

Use this method to set or retrieve the name of the DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the name of the Microsoft DHCP option in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $option->name();
#Modify name
$option->name("Static Route Option");
```

code( )

Use this method to set or retrieve the code value of the DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the code of the DHCP option. It must be an integer from 1 to 254.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get code
my $code = $option->code();
#Modify code
$option->code("12");
```

type( )

Use this method to set or retrieve the type value of the DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the type of the DHCP option. It must be one of the following values:

```
'binary'
'byte'
'array of byte'
'array of ip address pair'
'ip address'
'array of ip address'
'long integer'
'array of long integer'
'long'
'array of long'
'array of string'
'array of word'
'encapsulated'
'string'
```

```
'word'
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get type
my $type = $option->type();
#Modify type
$option->type("string");
```

value( )

Use this method to set or retrieve the custom value of the DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the data type of the DHCP option. If the type is set to 'array of...', the accepted type is a list of the specified types.

```
  "binary"                          - Binary data.

  "byte"                            - Specify a numeric value between 0 and 255.

  "encapsulated"                    - Encapsulated data.

  "ip address"                      - Specify an IPv4 address.

  "ip address pair"                 - Specify a pair of IPv4 addresses separated by a space.

  "long"                            - Specify a numeric value between 0 and 4294967295.

  "long integer"                    - Specify a numeric value between 0 and 1.84467441 * 10^19

  "string"                          - Specify either a value in ASCII text string or
                                      a list of hexadecimal characters (0-9, a-f, or A-F) without
spaces and separated by colons.

  "word"                            - Specify a numeric value between 0 and 65535.
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get value
my $value = $option->value();
#Modify value
$option->value("abc.com");
```

user_class( )

Use this method to set an option space name as the user class value of a DHCP option or to retrieve an option space name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the defined option space name in string format. The default user class name is "Default User Class".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get user_class
my $name = $option->user_class();
#Modify user_class
$option->user_class("Default User Class");
```

vendor_class( )

Use this method to set an option space name as the vendor class value of a DHCP option or to retrieve an option space name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the defined option space name in string format. The default vendor space name is "DHCP Standard Options".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get vendor_class
my $name = $option->vendor_class();
#Modify vendor_class
$option->vendor_class("DHCP Standard Options");
```

NAME

Infoblox::DHCP::MSServer - Microsoft (r) DHCP Server object.

DESCRIPTION

This object is used to reference a Microsoft DHCP server.

CONSTRUCTOR

```
my $member = Infoblox::DHCP::MSServer->new(
    address  => $address, #Required
    name     => $name,    #Optional
);
```

MODULE METHODS

This section describes all the functions that you can apply to a DHCP MSServer object.

Infoblox::DHCP::FixedAddr->member( ), Infoblox::DHCP::Network->members( ), Infoblox::DHCP::NetworkTemplate->members( ), Infoblox::DHCP::RangeTemplate->member( ), Infoblox::DHCP::Range->member( )

Use this function to specify a member for any of the above objects. See their respective documentation pages for parameters and return values.

Example

```
my $member1 = Infoblox::DHCP::MSServer->new(
    address => "10.0.0.1",
);

#Create the Network object with this member
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/255.0.0.0",
    members => [$member1],
);
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DHCP MSServer object.

address( )

Use this method to set or retrieve the address of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The Microsoft DNS server address in IPV4 format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address
my $address = $member->address();
#Modify address
$member->address("192.168.1.3");
```

name( )

Use this method to set or retrieve the name of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The Microsoft DNS server name in FQDN format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $member->name();
#Modify name
$member->name("msserver.com");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP MSServer object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a grid member object

my $grid_member = Infoblox::Grid::Member->new(
    name          => "hostname.com",
    ipv4addr      => "3.0.0.2",
    mask          => "255.0.0.0",
    gateway       => "3.0.0.1",
    comment       => "Script Generated"
    );
unless ($grid_member) {
       die("Construct grid member object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Grid member object created successfully\n";

#Adding the member object to appliance through session
```

```
my $response = $session->add( $grid_member );

unless ($response) {
    die("Add grid member failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Grid member added successfully \n";

my $msserver = Infoblox::Grid::MSServer->new(
                                            address                  => '10.0.0.1',
                                            comment                  => 'basic member',
                                            disable                  => 'true',
                                            extensible_attributes    => { Site => 'Local'},
                                            login                    => 'user',
                                            password                 => 'password',
                                            managing_member          => 'hostname.com',
                                            read_only                => 'false',
                                            synchronization_interval => 5,
                                            logging_mode             => 'minimum',
                                           );

unless ($msserver) {
       die("Construct grid MS DNS server object failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Grid MS DNS server object created successfully\n";

#Adding the member object to appliance through session
$response = $session->add( $msserver );

unless ($response) {
    die("Add grid MS DNS server failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print"Grid MS DNS server added successfully \n";
```

#Create a DHCP MSServer object

```
my $member1 = Infoblox::DHCP::MSServer->new(
    address => "10.0.0.1",
);

unless($member1) {
     die("Construct member failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create the Network object with this member
my $network = Infoblox::DHCP::Network->new(
                    network => "10.0.0.0/255.0.0.0",
                    comment => "add network",
                    members => [ $member1 ]
);

unless($network) {
             die("Construct Network object failed: ",
                   Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network object created successfully\n";

#Add the Network object into the Infoblox appliance through a session
$session->add($network)
     or die("Add Network object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP member object added to the network successfully\n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::MSSuperscope - Microsoft (r) Server Superscope object.

DESCRIPTION

A superscope is a feature of Microsoft DHCP servers. You can use a superscope to group and activate multiple ranges via a single object.

CONSTRUCTOR

```
 my $superscope = Infoblox::DHCP::Superscope->new(
                  name                          => $string,                              #Required
                  ranges                        => [ $dhcprange1,$dhcprange2,...],       #Required
                  comment                       => $string,                              #Optional
                  extattrs                      => { $string => $extattr, ... },         #Optional / Default
is undefined
                  extensible_attributes         => { $string => $string | $num, $string => [ $string |
$num, ... ], ... },
                                                                                         #Optional / Default
is undefined
                  network_view                  => $NetworkView,                         #Optional / Default
is the default network view
                  disable                       => "true" | "false",                     #Optional / Default
is "false"
            )
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a superscope object.

Infoblox::Session->add( )

Use this method to add a superscope object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
       #Construct an object
       my $superscope = Infoblox::DHCP::MSSuperscope->new(
                                                          name                  => 'test superscope',
                                                          comment               => 'test comment',
                                                          disable               => 'true',
                                                          network_view          => $view,
```

```
                                                    ranges                => [ $dhcp_range ],
                                                  );

    # Submit for addition
    my $response = $session->add( $superscope );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
    Apply the following attributes to get a specific superscope object:

    name                  - Optional. Name value for the superscope.
    comment               - Optional. Comment value for the superscope.
    network_view          - Optional. Network view in which the superscope is located. By default, all
   network views are searched.
    extattrs              - Optional. A hash reference containing extensible attributes.
    extensible_attributes  - Optional. A hash reference containing extensible attributes.
```

Examples

```
    my @retrieved_objs = $session->get(
                         object     => "Infoblox::DHCP::MSSuperscope",
                         name       => "test superscope" );

    my @retrieved_objs = $session->get(
                         object       => "Infoblox::DHCP::MSSuperscope",
                         name         => "other superscope",
                         network_view => "external" );

    my @retrieved_objs = $session->get(
                         object               => "Infoblox::DHCP::MSSuperscope",
                         extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify a superscope object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
    # Use this method to modify the comment.
    $superscope->comment("this is a modified comment");
    # Submit modification
    my $response = $session->modify( $superscope );
```

Infoblox::Session->remove( )

Use this method to remove a superscope object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the superscope object, and then submit this object for removal.

Example

```
    # Get the objects with the same name
    my @retrieved_objs = $session->get(
        object       => "Infoblox::DHCP::MSSuperscope",
        name         => "some superscope",
        newtork_view => "default" );
    # Find the desired object from the retrieved list.
    my $desired_superscope = $retrieved_objs[0];
    # Submit for removal
    my $response = $session->remove( $desired_superscope );
```

Infoblox::Session->search( )

Use this method to search for superscope objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
    Apply the following attributes to search for a superscope object:

     name                  - Optional. Name value for the superscope (regular expression).
```

```
  comment               - Optional. Comment value for the superscope (regular expression).
  network_view          - Optional. Network view in which the superscope is located. By default, all
network views are searched.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes  - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# search for superscope objects with comments ending with 'comment'
my @retrieved_objs = $session->search(
    object     => "Infoblox::DHCP::MSSuperscope",
    comment    => ".*comment" );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a superscope.

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $superscope->comment();
#Modify comment
$superscope->comment("Modifying the Superscope comment");
```

disable( )

Use this method to set or retrieve the disable flag of a superscope.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value for this field is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $superscope->disable();
#Modify disable
$superscope->disable("false");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a superscope object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $superscope->extattrs();
#Modify extattrs
$superscope->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes that are associated with a superscope object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $superscope->extensible_attributes();
#Modify extensible attributes
$superscope->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

name( )

Use this method to set or retrieve the name of the superscope.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the name of the superscope in string format. The string must not be longer than 256 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $superscope->name();
#Modify name
$superscope->name("superscope name");
```

network_view( )

Use this method to set or retrieve the network view of the superscope.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $superscope->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$superscope->network_view($nview);
```

ranges( )

Use this method to set or retrieve the DHCP ranges that are associated with this superscope.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::Range objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ranges
my $ref_options = $superscope->ranges();
#Modify ranges
$superscope->ranges([$range]); #$range is an Infoblox::DHCP::Range object
```

range_high_water_mark( )

Use this method to retrieve the percent above "Normal" when the DHCP utilization status becomes "High".

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get high-water mark
my $range_high_water_mark = $superscope->range_high_water_mark();
```

range_low_water_mark( )

Use this method to retrieve the percent below "Normal" when the DHCP utilization status becomes "Low".

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get low-water mark
my $range_low_water_mark = $superscope->range_low_water_mark();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a superscope object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP superscope object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
```

```
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create supporting objects, $host_name is the grid member's fqdn

```
my $ms_member = Infoblox::Grid::MSServer->new(
                                              address                  => '10.0.0.1',
                                              comment                  => 'basic member',
                                              disable                  => 'true',
                                              extensible_attributes    => { Site => 'Somewhere'},
                                              login                    => 'user',
                                              password                 => 'password',

NAME

Infoblox::DHCP::Network - DHCP Network object

DESCRIPTION

When DHCP services are configured on an appliance, a network must be defined that it serves. After a network is created, you can then create all the subnetworks individually or create a parent network that encompasses all the subnetworks.

CONSTRUCTOR

```
  my $network = Infoblox::DHCP::Network->new(
                network                         => $ipv4_subnet/prefix,             #Required, when
creating a network
                ipv4addr                        => $ipv4addr,                       #Use this parameter
instead of "network", when using a template with 'allow_any_netmask' set to false to create a network.
                authority                       => "true" | "false"| undef,         #Optional / Default
is undefined
                auto_create_reversezone         => "true" | "false"| undef,         #Optional / Default
is undefined
                bootfile                        => $filename | undef,               #Optional / Default
is undefined
                bootserver                      => $ipv4addr | $fqdn | undef,       #Optional / Default
is undefined
                comment                         => $string| undef,                  #Optional / Default
is undefined
                ddns_domainname                 => $string| undef,                  #Optional / Default
is undefined
                ddns_generate_hostname          => "true" | "false" | undef,        #Optional / Default
is undefined
                ddns_server_always_updates      => "true" | "false",                #Optional / Default

is an empty list
                override_ipam_email_addresses   => "true" | "false",                    #Optional / Default
value is "false"
                logic_filters                => [ $filter_name | $filter_obj, ...],     #Optional / Default
is undefined
                override_logic_filters      => "true' | 'false",                        #Optional / Default
value is "false"
                subscribe_settings          => $subscribe_settings,                     #Optional / Default
is undefined
                override_subscribe_settings => 'true' | 'false',                        #Optional / Default
is 'false'
                discovery_engine_type       => 'NETMRI' | 'NETWORK_INSIGHT' | 'VDISCOVERY' | 'UNKNOWN' |
'NONE', #Optional / Default is 'NONE'
                discovered_bridge_domain    => $string,                                 #Optional / Default
is undefined
                discovered_tenant           => $string,                                 #Optional / Default
is undefined
              );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that can apply to a DHCP Network object.

Infoblox::Session->add( )

Use this method to add a network object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values. Notice the syntax difference between simple adding a network and adding a network using a template.

Example

```
#Adding a network.
#Construct an object
my $network = Infoblox::DHCP::Network->new(
        network => "20.0.0.0/8",
);

# Submit for adding a network
my $response = $session->add( $network );

#Adding a network using template
#Construct an object
my $network = Infoblox::DHCP::Network->new(
        ipv4addr => '20.0.0.0',
        template => "mytemplate",
);

# Submit for adding a network
my $response = $session->add( $network );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching network objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
  Apply the following attributes to get a specific DHCP Network object:

    network                 - Optional. The IP address and netmask of a network in CIDR format.
    network_container       - Optional. The network container, in CIDR format, to which this network
belongs.
    network_view            - Optional. The network view in which the network is located. By default,
all network views are searched (except when contain_address is specified -- see below).
    extattrs                - Optional. A hash reference containing extensible attributes.
    extensible_attributes   - Optional. A hash reference containing extensible attributes.
    comment                 - Optional. A comment in string format.
    contains_address        - Optional. An IPv4 address in string format. If specified, all other
```

```
search attributes are ignored, except for network_view. When a value for this attribute is provided,
network_view defaults to the system-defined default network view, unless specified. The returned
network is the smallest network enclosing this IPv4 address.
  member                  - Optional. The member or Microsoft server serving DHCP for the network.
The valid value is an Infoblox::DHCP::Member or Infoblox::DHCP::MSServer object.
  discovered_bridge_domain - Optional. A bridge domain name in string format.
  discovered_tenant        - Optional. A tenant name in string format.
```

Examples

```
my  @result_array = $session->get(
     object         => "Infoblox::DHCP::Network" ,
     network        => "20.0.0.0/8",
     network_view => "default"
);

my  @result_array = $session->get(
     object                => "Infoblox::DHCP::Network" ,
     extensible_attributes => { 'Site' => 'Santa Clara' }
);

my  @result_array = $session->get(
     object  => "Infoblox::DHCP::Network" ,
     comment => "my-comment",
);

my  @result_array = $session->get(
     object  => "Infoblox::DHCP::Network" ,
     network_container => "10.0.0.0/16",
);

# Returns the smallest network enclosing 10.0.0.1 in the
# system-defined default network view.
my  @result_array = $session->get(
     object  => "Infoblox::DHCP::Network" ,
     contains_address => "10.0.0.1",
);

# Returns the smallest network enclosing 10.0.0.1 in the
# specified network view ($network_view_object).
my  @result_array = $session->get(
     object  => "Infoblox::DHCP::Network" ,
     contains_address => "10.0.0.1",
     network_view => $network_view_object,
);

# get a DHCP Network by member
my $member = Infoblox::DHCP::Member->new(
     name => "ib-10-0-0-1.infoblox.com",
     ipv4addr => "10.0.0.1",
);

my  @result_array = $session->get(
     object => "Infoblox::DHCP::Network",
     member => $member,
);

my @result_array = $session->get(
     object  => "Infoblox::DHCP::Network" ,
     discovered_bridge_domain => "domain1",
);

my @result_array = $session->get(
     object  => "Infoblox::DHCP::Network" ,
     discovered_tenant => "tenant1",
);
```

Infoblox::Session->modify( )

Use this method to modify a network object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify enable_ddns method.
$object->enable_ddns("true");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Key References

```
remove_options - Optional. A hash reference containing the following attributes:

+-------------------------------------------------------------------------------------------+
| reason             - Optional. The reason for removing the network in string format with  |
|                      a maximum of 256 bytes.                                              |
| send_rir_request   - Optional. Boolean flag that indicates whether the appliance should  |
|                      send an API or email request for Regional Internet Registry (RIR).  |
|                      Used when 'rir_organization' attribute has been defined.             |
+-------------------------------------------------------------------------------------------+
```

Example

```
 # Get the object under the same name
my  @result_array = $session->get(

       object        => "Infoblox::DHCP::Network" ,
       network       => "20.0.0.0/8",
       network_view  => "default"
         );

# find the desired object from the retrieved list.
my $desired_network = $result_array[0];

# Submit for removal
my $response = $session->remove(
    $desired_network,
    remove_options => {'reason' => 'Moved to B3', send_rir_request => 'true'} );
```

Infoblox::Session->search( )

Use this method to search for a DHCP Network object in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
 Apply the following attributes to search for a DHCP Network object:

  network                  - Optional. The IP address and netmask of a network in CIDR format.
  network_container        - Optional. The network container, in CIDR format, to which this network
belongs.
  network_view             - Optional. The network view in which the network is located. By default,
all network views are searched.
  extattrs                 - Optional. A hash reference containing extensible attributes.
  extensible_attributes    - Optional. A hash reference containing extensible attributes.
  comment                  - Optional. A comment in string format (regular expression).
  contains_address         - Optional. An IPv4 address in string format. If specified, all other
search attributes are ignored, except for network view. When a value for this attribute is provided,
network view defaults to the system-defined default network view, unless specified. The returned
network is the smallest network enclosing this IPv4 address.
  member                   - Optional. The member or Microsoft server serving DHCP for the network.
The valid value is an Infoblox::DHCP::Member or Infoblox::DHCP::MSServer object.
  discovered_bridge_domain - Optional. A bridge domain name in string format (regular expression).
  discovered_tenant        - Optional. A tenant name in string format (regular expression).
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# search for all DHCP Network objects
    my @retrieved_objs = $session->search(
      object       => "Infoblox::DHCP::Network",
      network      => '20\.0\.0\..*',
      network_view => "default"
    );

# search network by comment
    my @retrieved_objs = $session->search(
    object    => "Infoblox::DHCP::Network",
    comment   => "my-comment",
     );

# search network by network container
```

```
 my @result_array = $session->search(
      object  => "Infoblox::DHCP::Network" ,
      network_container => "10.0.0.0/16",
 );

# search for all DHCP Network objects defining "Santa Clara" for "Site" extensible attribute
    my @retrieved_objs = $session->search(
      object               => "Infoblox::DHCP::Network",
      extensible_attributes => { 'Site' => 'Santa Clara' }
    );

# Returns the smallest network enclosing 10.0.0.1 in the
# system-defined default network view.
    my @result_array = $session->search(
       object  => "Infoblox::DHCP::Network" ,
       contains_address => "10.0.0.1",
    );

# Returns the smallest network enclosing 10.0.0.1 in the
# specified network view ($network_view_object).
    my @result_array = $session->search(
       object  => "Infoblox::DHCP::Network" ,
       contains_address => "10.0.0.1",
       network_view => $network_view_object,
    );

 # search for all DHCP Network objects by member
 my $member = Infoblox::DHCP::Member->new(
      name => "ib-10-0-0-1.infoblox.com",
      ipv4addr => "10.0.0.1",
 );

 my  @result_array = $session->search(
      object => "Infoblox::DHCP::Network",
      member => $member,
 );

 # search network by discovered bridge domain
 my @result_array = $session->search(
      object  => "Infoblox::DHCP::Network" ,
      discovered_bridge_domain => "domain.*",
 );

 # search network by discovered tenant
 my @result_array = $session->search(
      object  => "Infoblox::DHCP::Network" ,
      discovered_tenant => "tenant.*",
 );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP Network object

authority( )

Use this method to set or retrieve the authority of a DHCP network object. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the authority or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherit the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
 # Get authority
 my $authority = $network->authority()
 # Modify authority
 $network->authority("true");
```

auto_create_reversezone( )

Use this method to set the auto_create_reversezone flag of a new DHCP network object. You can set this flag only when creating a new network object.

Include the specified parameter to set the attribute value.

Parameter

Specify "true" to set the auto_create_reversezone flag or "false" to deactivate/unset it. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
# Modify auto_create_reversezone
$network_container->auto_create_reversezone("true");
```

bootfile( )

Use this method to set or retrieve a bootfile attribute of a DHCP network object. You can configure the DHCP server to support clients that use boot file name option in their DHCPREQUEST messages. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::Network->bootserver() and Infoblox::DHCP::Network->nextserver().

Parameter

The name, in string format, of the file that the client must download. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get bootfile
my $bootfile = $network->bootfile();
# Modify bootfile
$network->bootfile("bootfile1");
#Un-override bootfile
$network->bootfile(undef);
```

bootserver( )

Use this method to set or retrieve a bootserver attribute of a DHCP network object. You can specify the name and/or IP address of the boot server that host needs to boot. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::Network->bootfile() and Infoblox::DHCP::Network->nextserver().

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get bootserver
my $bootserver = $network->bootserver();
# Modify bootserver
$network->bootserver("abc.domain.com");
#Un-override bootserver
$network->bootserver(undef);
```

comment( )

Use this method to set or retrieve a descriptive comment of a DHCP network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $network->comment();
# Modify comment
$network->comment("add a network");
```

cloud_info( )

Use this method to set or retrieve cloud API related information for the Infoblox::DHCP::Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a Infoblox::Grid::CloudAPI::Info object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $network_view->cloud_info();
# Modify cloud_info
$network_view->cloud_info($cloud_info_object);
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_dddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $network->ddns_domainname();
#Modify ddns_domainname
$network->ddns_domainname("test_domain.com");
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a DHCP network object. Enable this method to allow only the DHCP server for generating hostname. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to generate hostname or "false" to deactivate/unset it.The default value for this field is undefined, which indicates that this attribute inherit the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_generate_hostname
my $ddns_generate_hostname = $network->ddns_generate_hostname()
# Modify ddns_generate_hostname
$network->ddns_generate_hostname("true");
#Un-override
$network->ddns_generate_hostname(undef);
```

ddns_server_always_updates( )

Use this method to set or retrieve the ddns_server_always_updates flag of a DHCP network object. Enable this method to allow only the DHCP server to update DNS,regardless of the requests from the DHCP clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the flag that enables the DHCP server to always updates DNS or "false" to deactivate/unset it.The default value for this field is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_server_always_updates
my $ddns_server_always_updates = $network->ddns_server_always_updates()
# Modify ddns_server_always_updates
$network->ddns_server_always_updates("true");
```

ddns_ttl( )

Use this method to set or retrieve the DNS update Time to Live (TTL) value of a DHCP network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_dddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, that the update is cached. Zero indicates that the update is not cached. The default value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get DNS Update ttl
my $dns_ttl = $network->ddns_ttl();
#Modify DNS Update ttl
```

```
$network->ddns_ttl(1200);
```

ddns_update_fixed_addresses( )

Use this method to set or retrieve the ddns_update_fixed_addresses flag of a DHCP network object. By default, the DHCP server does not update DNS when it allocates a fixed address to a client. You can configure the DHCP server to update the A and PTR records of a client with a fixed address. When this feature is enabled and the DHCP server adds A and PTR records for a fixed address, the DHCP server never discards the records. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the appliance to update DNS when it assigns a fixed address to a client or "false" to disable it. The default value for this field is undefined, which indicates that this attribute inherit the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_update_fixed_addresses
my $ddns_update_fixed_addresses= $network->ddns_update_fixed_addresses()
# Modify ddns_update_fixed_addresses
$network->ddns_update_fixed_addresses("true");
#Un-override
$network->ddns_update_fixed_addresses(undef);
```

ddns_use_option81( )

Use this method to set or retrieve the ddns_use_option81 flag of a DHCP network object. Enable this method to define the settings for option 81 at the network level. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to Configure Support for Option 81 or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherit the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_use_option81
my $ddns_use_option81 = $network->ddns_use_option81()
# Modify ddns_use_option81
$network->ddns_use_option81("true");
# un-override ddns_use_option81
$network->ddns_use_option81(undef);
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute inherit the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp   $network  deny bootp
```

```
                =          ->          ();
#Modify deny_bootp
$network->deny_bootp("true");
```

disable( )

Use this method to set or retrieve the disable flag of a DHCP network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get disable
my $disable = $network->disable()
# Modify disable
$network->disable("true");
```

discovered_bridge_domain( )

Use this method to set or retrieve the discovered bridge domain name of a DHCP Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The desired bridge domain name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bridge domain
my $bridge_domain = $network->discovered_bridge_domain();
#Modify bridge domain
$network->discovered_bridge_domain("Domain");
```

discovered_tenant( )

Use this method to set or retrieve the discovered tenant name of a DHCP Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The desired tenant name in a string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get tenant
my $tenant = $network->discovered_tenant();
#Modify tenant
$network->discovered_tenant("Tenant");
```

discovery_basic_poll_setting( )

Use this method to set or retrieve the discovery_basic_poll_setting value of a DHCP Network object.

Include the specified parameter to set the attribute value.

Parameter

The valid value is object of the Infoblox::Grid::Discovery::BasicPollSettings manpage.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_basic_poll_setting
my $discovery_basic_poll_setting = $network->discovery_basic_poll_setting();
#Modify discovery_basic_poll_setting
$network->discovery_basic_poll_setting($poll_setting);
```

discovery_exclusion_range( )

Use this method to set or retrieve the discovery_exclusion_range value of a DHCP Network object.

Parameter

The valid value is an array of the Infoblox::DHCP::ExclusionRange manpage objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_exclusion_range
my $discovery_exclusion_range = $network->discovery_exclusion_range();
#Modify discovery_exclusion_range
$network->discovery_exclusion_range( [ $exclusion1, $exclusion2 ]);
```

discovery_member( )

Use this method to set or retrieve the discovery_member value of a DHCP Network object.

Parameter

The discovery member name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_member
my $discovery_member = $network->discovery_member();
#Modify discovery_member
$network->discovery_member("test.localdomain");
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $network->discover_now_status();
```

discovery_blackout_setting( )

Use this method to set or retrieve the discovery blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If port_control_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when discovery_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->discovery_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->discovery_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_blackout_setting
my $discovery_blackout_setting = $network->discovery_blackout_setting();
#Modify discovery_blackout_setting
$network->discovery_blackout_setting($blackout);
```

discovery_engine_type( )

Use this method to retrieve the DHCP Network discovery engine type. This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value that can be 'NETMRI', 'NETWORK_INSIGHT', 'VDISCOVERY', 'UNKNOWN' or 'NONE'.

Example

```
#Get discovery_engine_type
my $discovery_engine_type = $network->discovery_engine_type();
```

email_list( )

Use this method to set or retrieve the e-mail lists to which the appliance sends threshold e-mail messages.

If you enter e-mail addresses in the email_list, then the appliance sends DHCP threshold alarms to the e-mail addresses.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get email_list
my @email_list = $network->email_list();
#Modify email_list
$network->email_list( [ "admin\@test.com" ] );
```

enable_ddns( )

Use this method to set or retrieve the dynamic DNS updates flag of a DHCP network object. The DHCP server can send DDNS updates to DNS servers in the same grid and to external DNS servers. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the dynamic DNS updates flag or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherit the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ddns
my $enable_ddns = $network->enable_ddns()
# Modify enable_ddns
$network->enable_ddns("true");
# Un-override enable_ddns
$network->enable_ddns(undef);
```

enable_dhcp_thresholds( )

Use this method to set or retrieve DHCP thresholds at the network level. These thresholds are the high and low watermarks. If a DHCP range usage goes above or below these percentage values, the Infoblox appliance generates a syslog message and sends an SNMP notification.

Enable this flag to set DHCP thresholds values.

Parameter

Specify "true" to set the enable_dhcp_thresholds flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp_thresholds
my $enable_dhcp_thresholds = $network->enable_dhcp_thresholds();
#Modify enable_dhcp_thresholds
$network->enable_dhcp_thresholds("false");
```

enable_email_warnings( )

Use this method to send DHCP threshold warnings through e-mail.

Enable this flag if you want the appliance to send DHCP threshold warnings to the "email_list" provided when DHCP threshold is enabled.

Parameter

Specify "true" to set the enable_email_warnings flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_email_warnings
my $enable_email_warnings = $network->enable_email_warnings();
#Modify enable_email_warnings
$network->enable_email_warnings("false");
```

enable_discovery( )

Use this method to set or retrieve the enable_discovery value of a DHCP Network object. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_discovery method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_enable_discovery attribute to "false".

Enable this flag if you want to set discovery for this object.

Parameter

Specify "true" to set the enable_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_discovery
my $enable_discovery = $network->enable_discovery();
#Modify enable_discovery
$network->enable_discovery("false");
```

enable_ifmap_publishing( )

Use this method to set or retrieve ifmap publishing the option of a DHCP Network object. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set ifmap publishing option or "false" to deactivate/unset it. The default value 'false', which indicates that this attribute inherits the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable ifmap publishing
my $enable_ifmap_publishing = $network->enable_ifmap_publishing()
# Modify enable_ifmap_publishing
$network->enable_ifmap_publishing("true");
# Un-override enable_ifmap_publishing
$network->enable_ifmap_publishing(undef);
```

enable_immediate_discovery( )

Use this method to set or retrieve enable_immediate_discovery value of a DHCP Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_immediate_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_immediate_discovery
my $enable_immediate_discovery = $network->enable_immediate_discovery();
#Modify enable_immediate_discovery
$network->enable_immediate_discovery("false");
```

enable_snmp_warnings( )

Use this method to send DHCP threshold warnings through SNMP.

If the flag is enabled, then the appliance sends DHCP threshold warnings through SNMP messages when DHCP threshold is enabled.

Parameter

Specify "true" to set the enable_snmp_warnings flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_snmp_warnings
my $enable_snmp_warnings = $network->enable_snmp_warnings();
#Modify enable_snmp_warnings
$network->enable_snmp_warnings("false");
```

endpoint_sources( )

Use this method to retrieve the list of endpoints that provide object data. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an array of Infoblox::CiscoISE::Endpoint objects.

Example

```
#Get endpoint_sources value
my $endpoint_sources = $object->endpoint_sources();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP network object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $network->extattrs();
#Modify extattrs
$network->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP network object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $network->extensible_attributes();
#Modify extensible attributes
$network->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

high_water_mark( )

Use this method to set the percentage value for DHCP range usage above which the Infoblox appliance generates a syslog message and sends a warning.

When the percent of allocated addresses in a DHCP range exceeds the high watermark, the appliance generates a syslog message and sends a warning. Default value for this option is 95.

Parameter

The valid value is in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high_water_mark
my $high_water_mark = $network->high_water_mark();
#Modify high_water_mark
$network->high_water_mark("80");
```

high_water_mark_reset( )

Use this method to set or retrieve the high_water_mark_reset value. If the percentage of allocated addresses drops below this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The high watermark reset value must be lower than the high watermark value. The default value is 95.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high_water_mark_reset
my $high_water_mark_reset = $network->high_water_mark_reset();
#Modify high_water_mark_reset
$network->high_water_mark_reset(70);
```

ignore_id( )

Use this method to set or retrieve the ignore_id type of a DHCP network object. Indicates whether the appliance will ignore DHCP client IDs or MAC addresses. This setting overrides the upper-level settings.

Parameter

Valid values are 'NONE', 'CLIENT', or 'MACADDR'. The default is 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $network->ignore_id();
# Modify attribute value
$network->ignore_id('CLIENT');
#Un-override ignore_id
$network->ignore_id(undef);
```

ignore_mac_addresses( )

Use this method to set or retrieve the ignore_mac_addresses list of a DHCP network object. A list of MAC addresses the appliance will ignore. This setting overrides the upper-level settings.

If you enter MAC addresses in the ignore_mac_addresses, then the appliance will ignore them. If you enter empty array, then the appliance will ignore any MAC address.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $network->ignore_mac_addresses();
# Modify attribute value
$network->ignore_mac_addresses(["11::11::11::11::11::11"]);
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a DHCP Network object. If this flag is set to false, the appliance returns all the defined DHCP options to the client. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $network->ignore_dhcp_option_list_request();
# Modify ignore_dhcp_option_list_request
$network->ignore_dhcp_option_list_request("true");
#Do not override ignore_dhcp_option_list_request
$network->ignore_dhcp_option_list_request(undef);
```

ipam_email_addresses( )

Use this method to set or retrieve a list of IPAM Utilization email addresses.

Setting this method to a defined value implicitly sets the override_ipam_email_addresses method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_email_addresses attribute to "false".

Note that when ipam_email_addresses is set to a defined value and override_ipam_email_addresses is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_email_addresses(['admin@infoblox.com']); $object->override_ipam_email_addresses("false"); will set override_ipam_email_addresses to "false", and the sequence $object->override_ipam_email_addresses("false"); $object->ipam_email_addresses(['admin@infoblox.com']); will result in override_ipam_email_addresses="true".

Parameter

Valid value is an array reference that contains email addresses in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_email_addresses
my $ipam_email_addresses = $network->ipam_email_addresses();
#Modify ipam_email_addresses
$network->ipam_email_addresses($ipam_email_addresses);
```

ipam_trap_settings( )

Use this method to set or retrieve IPAM Utilization SNMP Trap settings.

Setting this method to a defined value implicitly sets the override_ipam_trap_settings method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_trap_settings attribute to "false".

Note that when ipam_trap_settings is set to a defined value and override_ipam_trap_settings is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_trap_settings($ipam_trap); $object->override_ipam_trap_settings("false"); will set override_ipam_trap_settings to "false", and the sequence $object->override_ipam_trap_settings("false"); $object->ipam_trap_settings($ipam_trap); will result in override_ipam_trap_settings="true".

Parameter

Valid value is an Infoblox::Grid::SNMP::IPAMTrap object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_trap_settings
my $ipam_trap_settings = $network->ipam_trap_settings();
#Modify ipam_trap_settings
$network->ipam_trap_settings($ipam_trap_settings);
```

ipam_threshold_settings( )

Use this method to set or retrieve IPAM Utilization SNMP Threshold settings.

Setting this method to a defined value implicitly sets the override_ipam_threshold_settings method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_threshold_settings attribute to "false".

Note that when ipam_threshold_settings is set to a defined value and override_ipam_threshold_settings is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_threshold_settings($ipam_threshold_settings); $object->override_ipam_trap_settings("false"); will set override_ipam_threshold_settings to "false", and the sequence $object->override_ipam_threshold_settings("false"); $object->ipam_threshold_settings($ipam_threshold_settings); will result in override_ipam_threshold_settings="true".

Parameter

Valid value is an Infoblox::Grid::SNMP::IPAMThreashold object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_threshold_settings
my $ipam_threshold_settings = $network->ipam_threshold_settings();
#Modify ipam_threshold_settings
$network->ipam_threshold_settings($ipam_threshold_settings);
```

lease_scavenge_time( )

Use this method to set or retrieve the lease_scavenge_time value of a DHCP Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_lease_scavenge_time method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_lease_scavenge_time attribute to "false".

Note that when lease_scavenge_time is set to a defined value and override_lease_scavenge_time is set to "false", the last operation takes precedence. Thus the sequence $object->lease_scavenge_time(604800); $object->override_lease_scavenge_time("false"); will set override_lease_scavenge_time to "false", and the sequence $object->override_lease_scavenge_time("false"); $object->lease_scavenge_time(604800); will result in override_lease_scavenge_time="true".

Parameter

An integer that specifies the period of time, in seconds, that free and backup leases remain in the database before they are automatically deleted. To disable lease scavenging, set the parameter to -1. The minimum positive value must be greater than 86400 seconds (1 day). The default value of this parameter is -1, which means that lease scavenging is disabled.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lease_scavenge_time
my $lease_scavenge = $network->lease_scavenge_time();
#Modify lease_scavenge_time
$network->lease_scavenge_time(30 * 24 * 60 * 60);
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Network.

Filters are used to screen address assignments in a DHCP Network if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $network->logic_filters();
#Modify logic_filters
$network->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an Infoblox::DHCP::Filter::MAC,
Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

low_water_mark( )

Use this method to set the percentage value for DHCP range usage below which the Infoblox appliance generates a syslog message and sends a warning.

When the percent of allocated addresses in a DHCP range goes below the low watermark, the appliance generates a syslog message and sends a warning. Default value for this option is 0.

Parameter

The valid value is in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low_water_mark
my $low_water_mark = $network->low_water_mark();
#Modify low_water_mark
$network->low_water_mark("10");
```

low_water_mark_reset( )

Use this method to set or retrieve the low_water_mark_reset value. If the percentage of allocated addresses exceeds this value, a

corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The low watermark reset value must be higher than the low watermark value. The default low watermark reset number is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low_water_mark_reset
my $low_water_mark_reset = $network->low_water_mark_reset();
#Modify low_water_mark_reset
$network->low_water_mark_reset(10);
```

members( )

Use this method to set or retrieve the member or Microsoft (r) server that serves DHCP for a network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Member or Infoblox::DHCP::MSServer objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $member1 = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
);

#Create the Network object with this member
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/8",
    members => [$member1],
);
```

mgm_private( )

Use this method to set or retrieve the flag that controls whether the object should be synced to the MGM or not.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when mgm_private is set to a defined value and override_mgm_private is set to "false", the last operation takes precedence. Thus the sequence $network->mgm_private("true"); $network->override_mgm_private("false"); will set override_mgm_private to "false", and the sequence $network->override_mgm_private("false"); $network->mgm_private("true"); will result in override_mgm_private="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable synchronization of the managed Grid with the MGM or 'false' to forbid it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get mgm_private value
my $value = $object->mgm_private();

#Modify mgm_private value
$object->mgm_private('true');
```

mgm_private_overridable( )

Use this method to retrieve the flag that indicates whether the overriding of 'mgm_private' flag is allowed or not. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get mgm_private_overridable value
my $value = $object->mgm_private_overridable();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $network->ms_ad_user_data();
```

network( )

Use this method to retrieve the network attribute of a DHCP network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network
my $network = $network->network();
```

network_container( )

Use this method to set or retrieve the network container of a DHCP network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the IP address and netmask of a network in CIDR format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network container
my $network_container = $network->network_container();
#Modify network container
$network->network_container("50.0.0.0/8");
```

network_view( )

Use this method to set or retrieve the network view of the DHCP network.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the network is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $network->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$network->network_view($nview);
```

nextserver( )

Use this method to set or retrieve the nextserver attribute of a DHCP network object. You can specify the name and/or IP address of the next server that the host needs to boot. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::Network->bootfile() and Infoblox::DHCP::Network->bootserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get nextserver
my $nextserver = $network->nextserver();
# Modify nextserver
$network->nextserver("blue.domain.com");
#Un-override nextserver
$network->nextserver(undef);
```

next_available_ip( )

Use this method to retrieve the next available IP `address(es)` in the network that was retrieved. Note that to use this method, the object MUST be retrieved through a get or search call, or created with an add call.

Parameter

The method accepts the following optional parameters:

`requested_num - The number of IP addresses requested. It must be a number between 1 and 20.`

```
  excluded - A reference to an array of addresses to be excluded from the results.
```

Returns

This method returns the next available IP address(es) in the network. If requested_num is not specified, a string with the next available address will be returned; otherwise, the method will return a reference to an array of addresses.

Within a DHCP Network object, the next available IP address(es) are the first addresses in this network that match all of the following rules:

```
   * Are not part of the passed 'excluded' parameter (if specified).
   * There is no A, PTR, fixed address or host address record matching this IP address
   * There is no bulk host record with this IP address
   * There is no unmanaged record matching this IP address
   * The IP address is not the network or broadcast address of this network
   * The IP address is not in any DHCP range within this network (including any exclusion range)
```

Example

```
# Retrieve a particular network
my @retrieved_objs = $session->get(
                          object   => "Infoblox::DHCP::Network",
                          network  => "10.0.0.0/8"
);

$dhcp_network = $retrieved_objs[0];

# Print the next available IP address in the network
print $dhcp_network->next_available_ip() . "\n";

# This will retrieve the next 10 available addresses and print the first one.
my $addressesref = $dhcp_network->next_available_ip(requested_num => 10);
print @$addressesref[0] . "\n";

# This will retrieve the next 10 available addresses and exclude two.
my $addressesref = $dhcp_network->next_available_ip(requested_num => 10, excluded => ["10.0.0.1",
"10.0.0.2"]);
```

next_available_network( )

Use this method to retrieve the next available network(s) in the network. Note that to use this method, the object MUST be retrieved through a get or search call, or created with an add call.

Parameter

The method accepts the following parameters:

```
  cidr - (required) The CIDR of the requested networks. It must be a value between 1 and 32,
inclusive.
  requested_num - (optional) The number of networks requested. It must be a value between 1 and 20,
inclusive.
  excluded - (optional) A reference to an array of networks to be excluded from the results.
```

Returns

This method returns the next available network(s) in the network. If requested_num is not specified, a string containing the next available network will be returned; otherwise, the method will return a reference to an array of networks.

A network cannot be returned as the next available network if it cannot be inserted; such as when any of the following conditions exist:

- It's parent network has a DHCP configuration assigned and therefore cannot be converted to a network container.

- It overlaps with an existing network or network container, regardless of whether the existing network has a greater or smaller CIDR than the requested CIDR.

- Its network address or broadcast address is used by a fixed address or a host configured for DHCP.

Example

```
# Retrieve a particular network
my @retrieved_objs = $session->get(
                          object   => "Infoblox::DHCP::Network",
                          network  => "10.0.0.0/8"
);

$network = $retrieved_objs[0];

# Print the next available IPv6 network in the network container
print $network->next_available_network(cidr => 12) . "\n";
```

```
# This will retrieve the next 10 available networks and print the first one
my $addressesref = $network->next_available_network(requested_num => 10, cidr => 12);
print @$addressesref[0] . "\n";

# This will retrieve the next 10 available networks and exclude two.
my $addressesref = $network->next_available_network(cidr => 12, requested_num => 10, excluded =>
['10.0.0.0/12']);
```

options( )

Use this method to set or retrieve the options value of a member DHCP server. DHCP options provide network configuration settings and various services available on the network for DHCP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $network->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name => "lease-time",
    value => 50
);

$network->options([$option1]);
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP Network is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$network->override_ddns_domainname( );
#Modifying override_ddns_domainname
$network->override_ddns_domainname("true");
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the DHCP Network is used, instead of the grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_ttl. Set the parameter to "false" to inherit the grid-level

setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_ttl
my $override_ddns_ttl=$network->override_ddns_ttl( );
#Modifying override_ddns_ttl
$network->override_ddns_ttl("true");
```

override_enable_ifmap_publishing( )

The override_enable_ifmap_publishing controls whether the enable_ifmap_publishing in the DHCP Network is used, instead of the grid default.

The override_enable_ifmap_publishing can be specified explicitly. It is also set implicitly when enable_ifmap_publishing is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ifmap_publishing. Set the parameter to "false" to inherit the grid-level setting for enable_ifmap_publishing.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_ifmap_publishing
my $override_enable_ifmap_publishing=$network->override_enable_ifmap_publishing( );
#Modifying override_enable_ifmap_publishing
$network->override_enable_ifmap_publishing("true");
```

override_blackout_setting( )

The override_blackout_setting attribute controls whether the discovery_blackout_setting and port_control_blackout_setting values in the object are used, instead of the grid default.

The override_blackout_setting attribute can be specified explicitly. It is also set implicitly when discovery_blackout_setting or port_control_blackout_setting is set to a defined value.

Parameter

Specify "true" to set the override_blackout_setting flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $network->override_blackout_setting();
# Modify attribute value
$network->override_blackout_setting('true');
```

override_ignore_id( )

The override_ignore_id controls whether the ignore_id in the DHCP network is used, instead of the upper-level default.

The override_ignore_id can be specified explicitly. It is also set implicitly when ignore_id is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ignore_id and ignore_mac_addresses. Set the parameter to "false" to inherit the upper-level setting for ignore_id and ignore_mac_addresses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network->override_ignore_id();
#Modifying attribute value
$network->override_ignore_id('true');
```

override_ipam_email_addresses( )

The override_ipam_email_addresses controls whether the ipam_email_addresses in the DHCP network is used, instead of the upper-level default.

The override_ipam_email_addresses can be specified explicitly. It is also set implicitly when ipam_email_addresses is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_email_addresses. Set the parameter to "false" to inherit the upper-level setting for ipam_email_addresses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network->override_ipam_email_addresses();
#Modifying attribute value
$network->override_ipam_email_addresses('true');
```

override_ipam_threshold_settings( )

The override_ipam_threshold_settings controls whether the ipam_threshold_settings in the DHCP network is used, instead of the upper-level default.

The override_ipam_threshold_settings can be specified explicitly. It is also set implicitly when ipam_threshold_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_threshold_settings. Set the parameter to "false" to inherit the upper-level setting for ipam_threshold_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network->override_ipam_threshold_settings();
#Modifying attribute value
```

```
$network->override_ipam_threshold_settings('true');
```

override_ipam_trap_settings( )

The override_ipam_trap_settings controls whether the ipam_trap_settings in the DHCP network is used, instead of the upper-level default.

The override_ipam_trap_settings can be specified explicitly. It is also set implicitly when ipam_trap_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_trap_settings. Set the parameter to "false" to inherit the upper-level setting for ipam_trap_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network->override_ipam_trap_settings();
#Modifying attribute value
$network->override_ipam_trap_settings('true');
```

override_lease_scavenge_time( )

The override_lease_scavenge_time attribute controls whether the lease_scavenge_time value in the DHCP network is used, instead of the upper-level default.

The override_lease_scavenge_time attribute can be specified explicitly. It is also set implicitly when lease_scavenge_time is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for lease_scavenge_time. Set the parameter to "false" to inherit the setting for lease_scavenge_time from the upper level.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_lease_scavenge_time
my $override_lease_scavenge_time=$network->override_lease_scavenge_time( );
#Modifying override_lease_scavenge_time
$network->override_lease_scavenge_time("true");
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value of the DHCP Network is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$network->override_logic_filters( );
#Modifying override_logic_filters
$network->override_logic_filters("true");
```

override_mgm_private( )

The override_mgm_private attribute controls whether the mgm_private value in the object is used, instead of the parent-level default.

The override_mgm_private attribute can be specified explicitly. It is also set implicitly when mgm_private is set to a defined value.

Note that setting override_mgm_private to 'false' sets the original 'mgm_private' value to 'false'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to 'true' to override the parent-level setting for mgm_private. Set the parameter to 'false' to inherit the parent-level setting for mgm_private.

The default value of this parameter is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get override_mgm_private value
my $value = $object->override_mgm_private( );

#Modify override_mgm_private value
$object->override_mgm_private('true');
```

override_subscribe_settings( )

The override_subscribe_settings attribute controls whether the subscribe_settings method values of the member are used, instead of the Grid default.

The override_subscribe_settings attribute can be specified explicitly. It is also set implicitly when subscribe_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for subscribe_settings. Set the parameter to "false" to inherit the Grid-level setting for subscribe_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_subscribe_settings value
my $override_subscribe_settings = $object->override_subscribe_settings( );
#Modify override_subscribe_settings value
$object->override_subscribe_settings("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP Network is used, instead of the grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when

update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

#Getting override_update_dns_on_lease_renewal my $override_update_dns_on_lease_renewal=$network->override_update_dns_on_lease_renewal( ); #Modifying override_update_dns_on_lease_renewal $network->override_update_dns_on_lease_renewal("true");

port_control_blackout_setting

Use this method to set or retrieve the port control blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when port_control_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->port_control_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->port_control_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get port_control_blackout_setting
my $port_control_blackout_setting = $network->port_control_blackout_setting();
#Modify port_control_blackout_setting
$network->port_control_blackout_setting($blackout);
```

pxe_lease_time( )

Use this method to set or retrieve the PXE lease time value of a DHCP Network object. Some hosts use PXE (Preboot Execution Environment) to boot remotely from a server. To better manage your IP resources, set a different lease time for PXE boot requests. You can configure the DHCP server to allocate an IP address with a shorter lease time to hosts that send PXE boot requests, so IP addresses are not leased longer than necessary. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, that the update is cached. Zero indicates that the update is not cached. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get PXE Lease Time
my $pxe_lease_time = $network->pxe_lease_time();
#Modify PXE Lease Time
```

```
$network->pxe_lease_time(1100);
#Un-override PXE Lease Time
$network->pxe_lease_time(undef);
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag at the network level.

If the flag is enabled, the leases are kept in the recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Parameter

Specify "true" to enable the recycle_leases flag or "false" to disable it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $network->recycle_leases();
#Modify recycle_leases
$network->recycle_leases("false");
```

resize( )

Use this method to resize a network. Note that to use this method, the object MUST be retrieved through a get or search call, or it must have been created with an add call.

Parameter

prefix - Required. The bitmask prefix length after resizing.

auto_create_reversezone - Optional. Boolean flag indicating whether or not to automatically create the reverse zone.

reason - Optional. The reason for resizing the network in string format with a maximum of 256 bytes. Used when 'rir_organization' attribute has been defined.

send_rir_request - Optional. Boolean flag that indicates whether the appliance should send an API or email request for Regional Internet Registry (RIR). Used when 'rir_organization' attribute has been defined.

Returns

The method returns true when the operation succeeds, and returns false when the operation fails. When an operation fails, the error code and error message are reported in the Session object's `status_code()` and `status_detail()` attributes.

Example

```
#Get Network through the session
my @retrieved_objs = $session->get(
        object =>"Infoblox::DHCP::Network" ,
        network => "20.0.0.0/8"
    );
my $network = $retrieved_objs[0];

# Expand a /24 network to a /16 network, inserting
# a corresponding reverse zone in the process.
my $response = $network->resize(
  prefix        => "16"
  auto_create_reversezone => "true"
) or die("Resize Network failed: ",
     $session->status_code() . ":" . $session->status_detail());
```

restart_if_needed( )

Use this method to set the flag that indicates whether DHCP service should be restarted on a member that is serving DHCP for the changed object referenced in a cloud API request.

Parameter

Specify true to restart the DHCP service.

Returns

None

Example

```
# Modify
$network->restart_if_needed('true');
```

rir( )

Use this method to retrieve the name of the Regional Internet Registry (RIR) that allocated this address space. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'RIPE' or 'NONE'.

Example

```
#Get rir
my $rir = $network->rir();
```

rir_organization( )

Use this method to set or retrieve the Regional Internet Registry (RIR) organization object.

Parameter

An Infoblox::Grid::RIR::Organization object.

You must enable support for RIR/SWIP at the Grid level before you can set attribute values. See Infoblox::Grid->enable_rir_swip() method.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_organization
my $rir_organization = $network->rir_organization();
#Modify rir_organization
$network->rir_organization($rir_org);
```

rir_registration_action( )

Use this method to set the registration action of Regional Internet Registry (RIR). This is a write-only attribute.

Parameter

Valid values are 'NONE', 'CREATE', 'MODIFY' or 'DELETE'.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set rir_registration_action
$network->rir_registration_action('CREATE');
```

rir_registration_status( )

Use this method to set or retrieve the registration status of Regional Internet Registry (RIR).

Parameter

The registration status of Regional Internet Registry (RIR), which can be 'REGISTERED' or 'NOT_REGISTERED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_registration_status
my $rir_registration_status = $network->rir_registration_status();
#Modify rir_registration_status
$network->rir_registration_status('NOT_REGISTERED');
```

last_rir_registration_update_sent( )

Use this method to retrieve the last registration update timestamp of Regional Internet Registry (RIR). This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_rir_registration_update_sent
my $last_rir_registration_update_sent = $network->last_rir_registration_update_sent();
```

last_rir_registration_update_status( )

Use this method to retrieve the last registration update status of Regional Internet Registry (RIR). This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_rir_registration_update_status
my $last_rir_registration_update_status = $network->last_rir_registration_update_status();
```

same_port_control_discovery_blackout( )

Use this method to set or retrieve the flag that enables using the same discovery blackout for port control blackout.

Parameter

Specify 'true' to use same discovery blackout for port control blackout or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $network->same_port_control_discovery_blackout();
# Modify attribute value
$network->same_port_control_discovery_blackout('true');
```

send_rir_request( )

Use this method to set the flag that indicates whether the appliance should send an API or email request for Regional Internet Registry (RIR). This is a write-only attribute.

Parameter

Specify "true" to set the send_rir_request flag or "false" to unset it.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set send_rir_request
$network->send_rir_request('true');
```

subscribe_settings( )

Use this method to set or retrieve the Cisco ISE subscribe settings.

Setting this method to a defined value implicitly sets the override_subscribe_settings method to "true". Setting the parameter to undefined causes the appliance to use the Cisco ISE endpoint default and automatically resets the override_subscribe_settings method to "false".

Note that when subscribe_settings is set to a defined value and override_subscribe_settings is set to "false", the last operation takes precedence. Thus the sequence $object->subscribe_settings($value); $object->override_subscribe_settings("false"); will set override_subscribe_settings to "false", and the sequence $object->override_subscribe_settings("false"); $object->subscribe_settings($value); will result in override_subscribe_settings="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::CiscoISE::SubscribeSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscribe_settings value
my $subscribe_settings = $object->subscribe_settings();
#Modify subscribe_settings value
$object->subscribe_settings($settings);
```

delete_reason( )

Use this method to specify the reason for deleting the Regional Internet Registry (RIR) registration request. This is a write-only attribute. This field is required only if 'rir_registration_action' is specified as 'DELETE'.

Parameter

The reason for deleting the RIR registration request in string format with a maximum of 256 bytes.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set delete_reason
$network->delete_reason('invalid');
```

template( )

Use this method to set or retrieve the network template name of a DHCP Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get template
my $template = $network->template();
#Modify template
$network->template("Template_Name");
```

zone_associations( )

Use this method to set or retrieve the associated zone information. Use the is_default boolean field of the Infoblox::DNS::Zone object to determine or specify the default zone in zone associations of a DHCP network. If the value is 'true', the associated zone is the default zone. Otherwise, it is not the default zone. The default value is 'false'.

Parameter

The valid value is an array reference that contains Infoblox::DNS::Zone object(s). The default value is an empty list. If the network has a parent, it is possible to use the zone associations of the parent by setting the parameter to undef.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Examples

```
#Getting zone associations
my $zone_associations = $network->zone_associations();
#Modifying zone_associations, setting 'test1.com' as the default zone
my $zone1 = Infoblox::DNS::Zone->new(
   name      => "test1.com",
   is_default => "true",
);
my $zone2 = Infoblox::DNS::Zone->new(
   name      => "test2.com",
   is_default => "false",
);
$network->zone_associations([$zone1, $zone2]);
#Clear zone_assocations
$network->zone_associations([]);
##Remove the override for zone_associations
$network->zone_associations(undef)
```

unmanaged( )

Use this method to set or retrieve the network status, which indicates whether the network is unmanaged or not.

Parameter

Specify true to mark the network as unmanaged or false as managed.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get network status
$unmanaged = $network->unmanaged();
# Modify network status
$network->unmanaged('true');
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

#Get update_dns_on_lease_renewal my $update_dns_on_lease_renewal=$network->update_dns_on_lease_renewal( ); #Modify update_dns_on_lease_renewal $network->update_dns_on_lease_renewal("true");

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP Network insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
master   => "192.168.1.2",
username => "admin",
password => "infoblox"
);
unless ($session) {
die("Construct session failed: ",
   Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP Network object

```
my $memberdhcp = Infoblox::DHCP::Member->new(
        name     => "infoblox.localdomain",
        ipv4addr => "192.168.1.2"
       );

my  $network = Infoblox::DHCP::Network->new(
        network => "10.0.0.0/8",
        comment => "add network",
        members => [$memberdhcp],
         );

my $response = $session->add($network)
   or die("Add Network failed: ",
         $session->status_code() . ":" . $session->status_detail());

print "Network added successfully\n";

#Search for a specific Network

#Search the network
my @retrieved_objs = $session->search(
object  => "Infoblox::DHCP::Network",
network => '10\.0\.0\..*'
);
my $object = $retrieved_objs[0];
unless ($object) {
die("Search Network failed: ",
    $session->status_code() . ":" . $session->status_detail());
}
print "Search Network found at least 1 matching entry\n";
```

#Get and modify a Network attribute

```
#Get Network through the session
my @retrieved_objs = $session->get(
       object =>"Infoblox::DHCP::Network" ,
       network => "10.0.0.0"
    );

my $object = $retrieved_objs[0];
```

```
unless ($object) {
die("Get Network object failed: ",
    $session->status_code() . ":" . $session->status_detail());
}
print "Get Network found at least 1 matching entry\n";
```

#Modify attributes of the specified Network attribute

```
$object->enable_ddns("true"); #Apply the changes

#Un-override bootfile
$object->bootfile(undef);

#Un-override bootserver
$object->bootserver(undef);

#Un-override nextserver
$object->nextserver(undef);

$session->modify($object)
or die("Modify Network attribute failed: ",
       $session->status_code() . ":" . $session->status_detail());

print "Network object modified successfully \n";
```

#Resize a network

```
#Get Network through the session
my @retrieved_objs = $session->get(
       object =>"Infoblox::DHCP::Network" ,
       network => "10.0.0.0/8"
    );
my $object = $retrieved_objs[0];

#Resize
my $response = $object->resize(
  prefix        => "16"
) or die("Resize Network failed: ",
     $session->status_code() . ":" . $session->status_detail());
```

#Remove a Network Object

```
  #Get Network object through the session
  my @retrieved_objs = $session->get(
       object  => "Infoblox::DHCP::Network" ,
       network => "10.0.0.0"
    );
```

my $object = $retrieved_objs[0];

unless ($object) { die("Get Network object failed: ", $session->status_code() . ":" . $session->status_detail()); }

```
print "Get Network object found at least 1 matching entry\n";
```

#Submit the object for removal

```
$session->remove($object)
or die("Remove Network failed: ",
    $session->status_code() . ":" . $session->status_detail());

print "Network removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::NetworkContainer - DHCP Network Container object

---

DESCRIPTION

A network can contain child networks. The network that contains the child network is called a network container.

CONSTRUCTOR

```
  my $network = Infoblox::DHCP::NetworkContainer->new(
                network                          => $ipv4_subnet/prefix,               #Required, when
creating a network container
                auto_create_reversezone          => "true" | "false",                  #Optional / Default
is "false"
                comment                          => $string| undef,                    #Optional / Default
is undefined
                remove_subnets                   => "true" | "false",                  #Optional / Default
is undefined
                rir_organization                 => $rir_org,                          #Optional / An
Infoblox::Grid::RIR::Organization object
                rir_registration_action          => 'NONE' | 'CREATE' | 'MODIFY' | 'DELETE',  # Optional /
write-only
                rir_registration_status          => 'NOT_REGISTERED' | 'REGISTERED',   #Optional / Default
is 'NOT_REGISTERED'
                send_rir_request                 => 'true' | 'false',                  #Optional / write-
only
                delete_reason                    => $string,                           #Optional / write-
only
                                                                                       #Required only if
'rir_registration_action' is specified as 'DELETE'
                mgm_private                      => "true" | "false",                  #Optional / Default
is "false"
                network_container                => $ipv4_subnet/prefix,               #Optional / Default
is "/"
                network_view                     => $NetworkView,                      #Optional / Default
is "default" network view
                zone_associations                => [$zone1, $zone2, ... ] | undef,    #Optional / Default
is an empty list
                extattrs                         => { $string => $extattr, ... },      #Optional / Default
is undefined
                extensible_attributes            => { $string => $string | $num, $string => [ $string |
$num, ... ], ... } #Required if 'rir_organization' attribute is defined. Otherwise is optional
                discovery_blackout_setting       => $blackout,                         #Optional
                port_control_blackout_setting    => $blackout,                         #Optional
                override_blackout_setting        => "true" | "false",                  #Optional / Default
value is "false"
                same_port_control_discovery_blackout  => "true" | "false",             #Optional / Default
value is "false"
                ipam_trap_settings                => $ipam_trap,                       #Optional / An
Infoblox::Grid::SNMP::IPAMTrap object
                override_ipam_trap_settings      => "true" | "false",                  #Optional / Default

is "false"
                enable_snmp_warnings             => "true" | "false",               #Optional / Default
is "false"
                high_water_mark                  => $number,                        #Optional / Default
is "95"
                high_water_mark_reset            => $number,                        #Optional / Default
is "95"
                ignore_dhcp_option_list_request  => "true" | "false" | undef,       #Optional / Default
is undefined
                ignore_id                        => 'NONE' | 'CLIENT' | 'MACADDR',  #Optional / Default
is 'NONE'
                ignore_mac_addresses             => [ "mac_addr", ... ] | undef     #Optional / Default
is undefined
                lease_scavenge_time              => $number,                        #Optional / Default
is "-1"
                low_water_mark                   => $number,                        #Optional / Default
is "0"
                low_water_mark_reset             => $number,                        #Optional / Default
is "0"
                nextserver                       => $ipv4addr | $fqdn | undef,      #Optional / Default
is undefined
                options                          => [$Option1,$Option2,...],        #Optional / Default
is empty list
                override_ddns_domainname         => "true" | "false",               #Optional / Default
value is "false"
                override_ddns_ttl                => "true" | "false",               #Optional / Default
value is "false"
                override_lease_scavenge_time     => "true" | "false",               #Optional / Default
value is "false"
                override_mgm_private             => "true" | "false",               #Optional / Default
value is "false"
                override_update_dns_on_lease_renewal => "true" | "false",           #Optional / Default
value is "false"
                override_ignore_id               => "true" | "false",               #Optional / Default
value is "false"
                pxe_lease_time                   => $num | undef,                   #Optional / Default
is undefined
                recycle_leases                   => "true" | "false" | undef,       #Optional / Default
is undefined
                update_dns_on_lease_renewal      => "true" | "false",               #Optional / Default
value is "false"
                logic_filters                    => [ $filter_name | $filter_obj, ...], #Optional /
Default is undefined
                override_logic_filters           => "true' | 'false",                #Optional /
Default value is "false"
                subscribe_settings          => $subscribe_settings,                 #Optional /
Default is undefined
```

```
                override_subscribe_settings => 'true' | 'false',                        #Optional /
Default is 'false'
                discovery_engine_type       => 'NETMRI' | 'NETWORK_INSIGHT' | 'VDISCOVERY' | 'UNKNOWN' |
'NONE', #Optional / Default is 'NONE'
                                );
```

You cannot set both extattrs and extensible_attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a DHCP Network Container object.

Infoblox::Session->add( )

Use this method to add a DHCP Network Container object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Adding a network container.
#Construct an object
my $network_container = Infoblox::DHCP::NetworkContainer->new(
      network => "20.0.0.0/8",
);

# Submit for adding a network container
my $response = $session->add( $network_container );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching DHCP Network Container objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
 Apply the following attributes to get a specific DHCP Network Container object:

  network               - Optional. The IP address and netmask of a network in CIDR format.
  network_container     - Optional. The network container, in CIDR format, to which this network
container belongs.
  network_view          - Optional. The network view in which the network is located. By default, all
network views are searched.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  comment               - Optional. A comment in string format.
```

Examples

```
 my  @result_array = $session->get(
      object       => "Infoblox::DHCP::NetworkContainer",
      network      => "20.0.0.0/8",
      network_view  => "default"
 );

 my  @result_array = $session->get(
      object               => "Infoblox::DHCP::NetworkContainer",
      extensible_attributes => { 'Site' => 'Santa Clara' }
 );

 my  @result_array = $session->get(
      object  => "Infoblox::DHCP::NetworkContainer",
      comment => "my-comment",
 );
```

Infoblox::Session->modify( )

Use this method to modify a DHCP Network Container object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify comment.
$network_container->comment("modified comment");
# Submit modification
my $response = $session->modify( $network_container );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Key References

```
remove_options - Optional. A hash reference containing the following attributes:

+-------------------------------------------------------------------------------------------+
| reason             - Optional. The reason for removing the network container in string    |
|                      format with a maximum of 256 bytes.                                  |
|                      Used when 'rir_organization' attribute has been defined.             |
| send_rir_request   - Optional. Boolean flag that indicates whether the appliance should  |
|                      send an API or email request for Regional Internet Registry (RIR).   |
|                      Used when 'rir_organization' attribute has been defined.             |
+-------------------------------------------------------------------------------------------+
```

Example

```
 # Get the object under the same name
my  @result_array = $session->get(

       object       => "Infoblox::DHCP::NetworkContainer" ,
       network      => "20.0.0.0/8",
       network_view  => "default"
         );

 # Find the desired object in the retrieved list.
 my $network_container = $result_array[0];

 # Submit for removal
 my $response = $session->remove(
     $network_container,
     remove_options => {'reason' => 'Moved to B3', send_rir_request => 'true'} );
```

Infoblox::Session->search( )

Use this method to search for a DHCP Network Container object in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
 Apply the following attributes to search for a DHCP Network Container object:

  network              - Optional. The IP address and netmask of a network in CIDR format (regular
expression).
  network_container    - Optional. The network container, in CIDR format, to which this network
container belongs.
  network_view         - Optional. The network view in which the network is located. By default, all
network views are searched.
  extattrs             - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  comment              - Optional. A comment in string format (regular expression).
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
 # search for all DHCP Network Container objects
     my @retrieved_objs = $session->search(
       object       => "Infoblox::DHCP::NetworkContainer",
       network      => '20\.0\.0\..*',
       network_view => "default"
     );

 # search network by comment
     my @retrieved_objs = $session->search(
       object    => "Infoblox::DHCP::NetworkContainer",
       comment   => "my-comment",
     );

 # search for all DHCP Network Container objects defining "Santa Clara" for "Site" extensible
attribute
     my @retrieved_objs = $session->search(
       object               => "Infoblox::DHCP::NetworkContainer",
       extensible_attributes => { 'Site' => 'Santa Clara' }
     );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP Network Container object.

authority( )

Use this method to set or retrieve the authority of a DHCP Network Container object. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the authority or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherit the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get authority
my $authority = $network_container->authority()
# Modify authority
$network_container->authority("true");
```

auto_create_reversezone( )

Use this method to set the auto_create_reversezone flag of a DHCP Network Container object.

Include the specified parameter to set the attribute value. This is a write-only attribute and cannot be retrieved after it is set.

Parameter

Specify "true" to set the auto_create_reversezone flag or "false" to deactivate/unset it. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
# Modify auto_create_reversezone
$network_container->auto_create_reversezone("true");
```

bootfile( )

Use this method to set or retrieve a bootfile attribute of a DHCP Network Container object. You can configure the DHCP server to support clients that use boot file name option in their DHCPREQUEST messages. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::NetworkContainer->bootserver() and Infoblox::DHCP::NetworkContainer->nextserver().

Parameter

The name, in string format, of the file that the client must download. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get bootfile
my $bootfile = $network_container->bootfile();
# Modify bootfile
$network_container->bootfile("bootfile1");
#Un-override bootfile
$network_container->bootfile(undef);
```

bootserver( )

Use this method to set or retrieve a bootserver attribute of a DHCP Network Container object. You can specify the name and/or IP address of the boot server that host needs to boot. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::NetworkContainer->bootfile() and Infoblox::DHCP::NetworkContainer->nextserver().

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get bootserver
my $bootserver = $network_container->bootserver();
# Modify bootserver
$network_container->bootserver("abc.domain.com");
#Un-override bootserver
$network_container->bootserver(undef);
```

comment( )

Use this method to set or retrieve a descriptive comment for a DHCP Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network container in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $network_container->comment();
# Modify comment
$network_container->comment("add a network");
```

cloud_info( )

Use this method to set or retrieve cloud API related information for the Infoblox::DHCP::NetworkContainer object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a Infoblox::Grid::CloudAPI::Info object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $network_view->cloud_info();
# Modify cloud_info
$network_view->cloud_info($cloud_info_object);
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_dddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $network_container->ddns_domainname();
#Modify ddns_domainname
$network_container->ddns_domainname("test_domain.com");
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a DHCP Network Container object. Enable this method to allow only the DHCP server for generating hostname. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to generate hostname or "false" to deactivate/unset it.The default value for this field is undefined, which indicates that this attribute inherit the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_generate_hostname
my $ddns_generate_hostname = $network_container->ddns_generate_hostname()
# Modify ddns_generate_hostname
$network_container->ddns_generate_hostname("true");
#Un-override
$network_container->ddns_generate_hostname(undef);
```

ddns_server_always_updates( )

Use this method to set or retrieve the ddns_server_always_updates flag of a DHCP Network Container object. Enable this method to allow only the DHCP server to update DNS regardless of the requests from the DHCP clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the flag that enables the DHCP server to always updates DNS or "false" to deactivate/unset it.The default value for this field is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_server_always_updates
my $ddns_server_always_updates = $network_container->ddns_server_always_updates()
# Modify ddns_server_always_updates
```

```
$network_container->ddns_server_always_updates("true");
```

ddns_ttl( )

Use this method to set or retrieve the DNS update Time to Live (TTL) value of a DHCP Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_dddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, the update is cached. Zero indicates that the update is not cached. The default value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get DNS Update ttl
my $dns_ttl = $network_container->ddns_ttl();
#Modify DNS Update ttl
$network_container->ddns_ttl(1200);
```

ddns_update_fixed_addresses( )

Use this method to set or retrieve the ddns_update_fixed_addresses flag of a DHCP Network Container object. By default, the DHCP server does not update DNS when it allocates a fixed address to a client. You can configure the DHCP server to update the A and PTR records of a client with a fixed address. When this feature is enabled and the DHCP server adds A and PTR records for a fixed address, the DHCP server never discards the records. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable the appliance to update DNS when it assigns a fixed address to a client or "false" to disable it. The default value for this field is undefined, which indicates that this attribute inherit the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_update_fixed_addresses
my $ddns_update_fixed_addresses= $network_container->ddns_update_fixed_addresses()
# Modify ddns_update_fixed_addresses
$network_container->ddns_update_fixed_addresses("true");
#Un-override
$network_container->ddns_update_fixed_addresses(undef);
```

ddns_use_option81( )

Use this method to set or retrieve the ddns_use_option81 flag of a DHCP Network Container object. Enable this method to define the settings for option 81 at the network level. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to Configure Support for Option 81 or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherit the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_use_option81
my $ddns_use_option81 = $network_container->ddns_use_option81()
# Modify ddns_use_option81
$network_container->ddns_use_option81("true");
# un-override ddns_use_option81
$network_container->ddns_use_option81(undef);
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute inherit the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $network_container->deny_bootp();
#Modify deny_bootp
$network_container->deny_bootp("true");
```

discovery_basic_poll_setting( )

Use this method to set or retrieve the discovery_basic_poll_setting value of a DHCP Network Container object.

Include the specified parameter to set the attribute value.

Parameter

The valid value is object of the Infoblox::Grid::Discovery::BasicPollSettings manpage.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_basic_poll_setting
my $discovery_basic_poll_setting = $network->discovery_basic_poll_setting();
#Modify discovery_basic_poll_setting
$network->discovery_basic_poll_setting($poll_setting);
```

discovery_member( )

Use this method to set or retrieve the discovery_member value of a DHCP Network Container object.

Parameter

The discovery member name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_member
my $discovery_member = $network->discovery_member();
#Modify discovery_member
$network->discovery_member("test.localdomain");
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $network->discover_now_status();
```

discovery_blackout_setting( )

Use this method to set or retrieve the discovery blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If port_control_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when discovery_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->discovery_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->discovery_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_blackout_setting
my $discovery_blackout_setting = $network->discovery_blackout_setting();
#Modify discovery_blackout_setting
$network->discovery_blackout_setting($blackout);
```

discovery_engine_type( )

Use this method to retrieve the DHCP Network Container container discovery engine type. This attribute is read-only.

Parameter

None.

Returns

The method returns the attribute value that can be 'NETMRI', 'NETWORK_INSIGHT', 'VDISCOVERY', 'UNKNOWN' or 'NONE'.

Example

```
#Get discovery_engine_type
my $discovery_engine_type = $network_container->discovery_engine_type();
```

email_list( )

Use this method to set or retrieve the e-mail lists to which the appliance sends threshold e-mail messages.

If you enter e-mail addresses in the email_list, then the appliance sends DHCP threshold alerts to the e-mail addresses.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get email_list
my @email_list = $network_container->email_list();
#Modify email_list
$network_container->email_list( [ "admin\@test.com" ] );
```

enable_ddns( )

Use this method to set or retrieve the dynamic DNS updates flag of a DHCP Network Container object. The DHCP server can send DDNS updates to DNS servers in the same grid and to external DNS servers. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the dynamic DNS updates flag or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute inherit the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ddns
my $enable_ddns = $network_container->enable_ddns()
# Modify enable_ddns
$network_container->enable_ddns("true");
# Un-override enable_ddns
$network_container->enable_ddns(undef);
```

enable_dhcp_thresholds( )

Use this method to set or retrieve DHCP thresholds at the network container level. These thresholds are the high and low watermarks. If a DHCP Network Container usage goes above or below these percentage values, the Infoblox appliance generates a syslog message and sends an SNMP notification.

Enable this flag to set DHCP thresholds values.

Parameter

Specify "true" to set the enable_dhcp_thresholds flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp_thresholds
my $enable_dhcp_thresholds = $network_container->enable_dhcp_thresholds();
#Modify enable_dhcp_thresholds
$network_container->enable_dhcp_thresholds("false");
```

enable_email_warnings( )

Use this method to send DHCP threshold warnings through e-mail.

Enable this flag if you want the appliance to send DHCP threshold warnings to the "email_list" provided when DHCP threshold is enabled.

Parameter

Specify "true" to set the enable_email_warnings flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_email_warnings
my $enable_email_warnings = $network_container->enable_email_warnings();
#Modify enable_email_warnings
$network_container->enable_email_warnings("false");
```

enable_discovery( )

Use this method to set or retrieve the enable_discovery value of a DHCP Network Container object. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_discovery method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_enable_discovery attribute to "false".

Enable this flag if you want to set discovery for this object.

Parameter

Specify "true" to set the enable_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_discovery
my $enable_discovery = $network->enable_discovery();
#Modify enable_discovery
$network->enable_discovery("false");
```

enable_immediate_discovery( )

Use this method to set or retrieve enable_immediate_discovery value of a DHCP Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_immediate_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_immediate_discovery
my $enable_immediate_discovery = $network->enable_immediate_discovery();
#Modify enable_immediate_discovery
$network->enable_immediate_discovery("false");
```

enable_snmp_warnings( )

Use this method to send DHCP threshold warnings through SNMP.

If the flag is enabled, then the appliance sends DHCP threshold warnings through SNMP messages when DHCP threshold is enabled.

Parameter

Specify "true" to set the enable_snmp_warnings flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_snmp_warnings
my $enable_snmp_warnings = $network_container->enable_snmp_warnings();
```

```
#Modify enable_snmp_warnings
$network_container->enable_snmp_warnings("false");
```

endpoint_sources( )

Use this method to retrieve the list of endpoints that provide object data. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an array of Infoblox::CiscoISE::Endpoint objects.

Example

```
#Get endpoint_sources value
my $endpoint_sources = $object->endpoint_sources();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Network Container object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $network_container->extattrs();
#Modify extattrs
$network_container->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Network Container object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $network_container->extensible_attributes();
#Modify extensible attributes
$network_container->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

high_water_mark( )

Use this method to set the percentage value for DHCP Network Container usage above which the Infoblox appliance generates a syslog message and sends a warning.

When the percentage of allocated addresses in a DHCP Network Container exceeds the high watermark, the appliance generates a syslog message and sends a warning. Default value for this option is 95.

Parameter

The valid value is in sting format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high_water_mark
my $high_water_mark = $network_container->high_water_mark();
#Modify high_water_mark
$network_container->high_water_mark("80");
```

high_water_mark_reset( )

Use this method to set or retrieve the high_water_mark_reset value. If the percentage of allocated addresses drops below this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The high watermark reset value must be lower than the high watermark value. The default value is 95.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high_water_mark_reset
my $high_water_mark_reset = $network_container->high_water_mark_reset();
#Modify high_water_mark_reset
$network_container->high_water_mark_reset(70);
```

ignore_id( )

Use this method to set or retrieve the ignore_id type of a DHCP Network Container object. Indicates whether the appliance will ignore DHCP client IDs or MAC addresses. This setting overrides the upper-level settings.

Parameter

Valid values are 'NONE', 'CLIENT', or 'MACADDR'. The default is 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $network_container->ignore_id();
# Modify attribute value
$network_container->ignore_id('CLIENT');
#Un-override ignore_id
$network_container->ignore_id(undef);
```

ignore_mac_addresses( )

Use this method to set or retrieve the ignore_mac_addresses list of a DHCP Network Container object. A list of MAC addresses the appliance will ignore. This setting overrides the upper-level settings.

If you enter MAC addresses in the ignore_mac_addresses, then the appliance will ignore them. If you enter empty array, then the appliance will ignore any MAC address.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $network_container->ignore_mac_addresses();
# Modify attribute value
$network_container->ignore_mac_addresses(["11::11::11::11::11::11"]);
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a DHCP Network Container object. If this flag is set to false, the appliance returns all the defined DHCP options to the client. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $network_container->ignore_dhcp_option_list_request();
# Modify ignore_dhcp_option_list_request
$network_container->ignore_dhcp_option_list_request("true");
#Do not override ignore_dhcp_option_list_request
$network_container->ignore_dhcp_option_list_request(undef);
```

ipam_email_addresses( )

Use this method to set or retrieve a list of IPAM Utilization email addresses.

Setting this method to a defined value implicitly sets the override_ipam_email_addresses method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_email_addresses attribute to "false".

Note that when ipam_email_addresses is set to a defined value and override_ipam_email_addresses is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_email_addresses(['admin@infoblox.com']); $object->override_ipam_email_addresses("false"); will set override_ipam_email_addresses to "false", and the sequence $object->override_ipam_email_addresses("false"); $object->ipam_email_addresses(['admin@infoblox.com']); will result in override_ipam_email_addresses="true".

Parameter

Valid value is an array reference that contains email addresses in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_email_addresses
my $ipam_email_addresses = $network_container->ipam_email_addresses();
#Modify ipam_email_addresses
$network_container->ipam_email_addresses($ipam_email_addresses);
```

ipam_trap_settings( )

Use this method to set or retrieve IPAM Utilization SNMP Trap settings.

Setting this method to a defined value implicitly sets the override_ipam_trap_settings method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_trap_settings attribute to "false".

Note that when ipam_trap_settings is set to a defined value and override_ipam_trap_settings is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_trap_settings($ipam_trap); $object->override_ipam_trap_settings("false"); will set

override_ipam_trap_settings to "false", and the sequence $object->override_ipam_trap_settings("false"); $object->ipam_trap_settings($ipam_trap); will result in override_ipam_trap_settings="true".

Parameter

Valid value is an Infoblox::Grid::SNMP::IPAMTrap object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_trap_settings
my $ipam_trap_settings = $network_container->ipam_trap_settings();
#Modify ipam_trap_settings
$network_container->ipam_trap_settings($ipam_trap_settings);
```

ipam_threshold_settings( )

Use this method to set or retrieve IPAM Utilization SNMP Threshold settings.

Setting this method to a defined value implicitly sets the override_ipam_threshold_settings method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_threshold_settings attribute to "false".

Note that when ipam_threshold_settings is set to a defined value and override_ipam_threshold_settings is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_threshold_settings($ipam_threshold_settings); $object->override_ipam_trap_settings("false"); will set override_ipam_threshold_settings to "false", and the sequence $object->override_ipam_threshold_settings("false"); $object->ipam_threshold_settings($ipam_threshold_settings); will result in override_ipam_threshold_settings="true".

Parameter

Valid value is an Infoblox::Grid::SNMP::IPAMThreashold object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_threshold_settings
my $ipam_threshold_settings = $network_container->ipam_threshold_settings();
#Modify ipam_threshold_settings
$network_container->ipam_threshold_settings($ipam_threshold_settings);
```

mgm_private( )

Use this method to set or retrieve the flag that controls whether the object should be synced to the MGM or not.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when mgm_private is set to a defined value and override_mgm_private is set to "false", the last operation takes precedence. Thus the sequence $network->mgm_private("true"); $network->override_mgm_private("false"); will set override_mgm_private to "false", and the sequence $network->override_mgm_private("false"); $network->mgm_private("true"); will result in override_mgm_private="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable synchronization of the managed Grid with the MGM or 'false' to forbid it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get mgm_private value
my $value = $object->mgm_private();

#Modify mgm_private value
$object->mgm_private('true');
```

mgm_private_overridable( )

Use this method to retrieve the flag that indicates whether the overriding of 'mgm_private' flag is allowed or not. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get mgm_private_overridable value
my $value = $object->mgm_private_overridable();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $network_container->ms_ad_user_data();
```

lease_scavenge_time( )

Use this method to set or retrieve the lease_scavenge_time value of a DHCP Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_lease_scavenge_time method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_lease_scavenge_time attribute to "false".

Note that when lease_scavenge_time is set to a defined value and override_lease_scavenge_time is set to "false", the last operation takes precedence. Thus the sequence $object->lease_scavenge_time(604800); $object->override_lease_scavenge_time("false"); will set override_lease_scavenge_time to "false", and the sequence $object->override_lease_scavenge_time("false"); $object->lease_scavenge_time(604800); will result in override_lease_scavenge_time="true".

Parameter

An integer that specifies the period of time, in seconds, that free and backup leases remain in the database before they are automatically deleted. To disable lease scavenging, set the parameter to -1. The minimum positive value must be greater than 86400 seconds (1 day). The default value of this parameter is -1, which means that lease scavenging is disabled.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lease_scavenge_time
my $lease_scavenge = $network_container->lease_scavenge_time();
#Modify lease_scavenge_time
```

```
$network_container->lease_scavenge_time(30 * 24 * 60 * 60);
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Network Container.

Filters are used to screen address assignments in a DHCP Network Container if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $network_container->logic_filters();
#Modify logic_filters
$network_container->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an
Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

low_water_mark( )

Use this method to set the percentage value for DHCP Network Container usage below which the Infoblox appliance generates a syslog message and sends a warning.

When the percentage of allocated addresses in a DHCP Network Container goes below the low watermark, the appliance generates a syslog message and sends a warning. Default value for this option is 0.

Parameter

The valid value is in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low_water_mark
my $low_water_mark = $network_container->low_water_mark();
#Modify low_water_mark
$network_container->low_water_mark("10");
```

low_water_mark_reset( )

Use this method to set or retrieve the low_water_mark_reset value. If the percentage of allocated addresses exceeds this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The low watermark reset value must be

higher than the low watermark value. The default low watermark reset number is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low_water_mark_reset
my $low_water_mark_reset = $network_container->low_water_mark_reset();
#Modify low_water_mark_reset
$network_container->low_water_mark_reset(10);
```

network( )

Use this method to retrieve the network attribute of a DHCP Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the address and netmask of the network in CIDR format (example: 10.0.0.0/8).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network
my $network = $network_container->network();
```

override_blackout_setting( )

The override_blackout_setting attribute controls whether the discovery_blackout_setting and port_control_blackout_setting values in the object are used, instead of the Grid default.

The override_blackout_setting attribute can be specified explicitly. It is also set implicitly when discovery_blackout_setting or port_control_blackout_setting is set to a defined value.

Parameter

Specify "true" to set the override_blackout_setting flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $network->override_blackout_setting();
# Modify attribute value
$network->override_blackout_setting('true');
```

nextserver( )

Use this method to set or retrieve the nextserver attribute of a DHCP Network Container object. You can specify the name and/or IP address of the next server that the host needs to boot. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::NetworkContainer->bootfile() and Infoblox::DHCP::NetworkContainer->bootserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get nextserver
my $nextserver = $network_container->nextserver();
# Modify nextserver
$network_container->nextserver("blue.domain.com");
#Un-override nextserver
$network_container->nextserver(undef);
```

options( )

Use this method to set or retrieve the options value of a member DHCP server. DHCP options provide network configuration settings and various services available on the network for DHCP.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $network_container->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name => "lease-time",
    value => 50
);

$network_container->options([$option1]);
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP Network Container is used, instead of the Grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ddns_domainname. Set the parameter to "false" to inherit the upper-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$network_container->override_ddns_domainname( );
#Modifying override_ddns_domainname
$network_container->override_ddns_domainname("true");
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the DHCP Network Container is used, instead of the Grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ddns_ttl. Set the parameter to "false" to inherit the upper-level setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_ttl
my $override_ddns_ttl=$network_container->override_ddns_ttl( );
#Modifying override_ddns_ttl
$network_container->override_ddns_ttl("true");
```

override_ignore_id( )

The override_ignore_id controls whether the ignore_id in the DHCP Network Container is used, instead of the upper-level default.

The override_ignore_id can be specified explicitly. It is also set implicitly when ignore_id is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ignore_id and ignore_mac_addresses. Set the parameter to "false" to inherit the upper-level setting for ignore_id and ignore_mac_addresses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network_container->override_ignore_id();
#Modifying attribute value
$network_container->override_ignore_id('true');
```

override_ipam_email_addresses( )

The override_ipam_email_addresses controls whether the ipam_email_addresses in the DHCP network container is used, instead of the upper-level default.

The override_ipam_email_addresses can be specified explicitly. It is also set implicitly when ipam_email_addresses is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_email_addresses. Set the parameter to "false" to inherit the upper-level setting for ipam_email_addresses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network_container->override_ipam_email_addresses();
#Modifying attribute value
$network_container->override_ipam_email_addresses('true');
```

override_ipam_threshold_settings( )

The override_ipam_threshold_settings controls whether the ipam_threshold_settings in the DHCP network container is used, instead of the upper-level default.

The override_ipam_threshold_settings can be specified explicitly. It is also set implicitly when ipam_threshold_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_threshold_settings. Set the parameter to "false" to inherit the upper-level setting for ipam_threshold_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network_container->override_ipam_threshold_settings();
#Modifying attribute value
$network_container->override_ipam_threshold_settings('true');
```

override_ipam_trap_settings( )

The override_ipam_trap_settings controls whether the ipam_trap_settings in the DHCP network container is used, instead of the upper-level default.

The override_ipam_trap_settings can be specified explicitly. It is also set implicitly when ipam_trap_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_trap_settings. Set the parameter to "false" to inherit the upper-level setting for ipam_trap_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network_container->override_ipam_trap_settings();
#Modifying attribute value
$network_container->override_ipam_trap_settings('true');
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value of the DHCP Network Container is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$network_container->override_logic_filters( );
#Modifying override_logic_filters
$network_container->override_logic_filters("true");
```

override_lease_scavenge_time( )

The override_lease_scavenge_time attribute controls whether the lease_scavenge_time value in the DHCP Network Container is used, instead of the upper-level default.

The override_lease_scavenge_time attribute can be specified explicitly. It is also set implicitly when lease_scavenge_time is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for lease_scavenge_time. Set the parameter to "false" to inherit the setting for lease_scavenge_time from the upper level.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_lease_scavenge_time
my $override_lease_scavenge_time=$network_container->override_lease_scavenge_time( );
#Modifying override_lease_scavenge_time
$network_container->override_lease_scavenge_time("true");
```

override_mgm_private( )

The override_mgm_private attribute controls whether the mgm_private value in the object is used, instead of the parent-level default.

The override_mgm_private attribute can be specified explicitly. It is also set implicitly when mgm_private is set to a defined value.

Note that setting override_mgm_private to 'false' sets the original 'mgm_private' value to 'false'.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to 'true' to override the parent-level setting for mgm_private. Set the parameter to 'false' to inherit the parent-level setting for mgm_private.

The default value of this parameter is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Note that this member is loaded on on-demand basis, so to retrieve the value the object must have been retrieved from the session first.

Example

```
#Get override_mgm_private value
my $value = $object->override_mgm_private( );

#Modify override_mgm_private value
$object->override_mgm_private('true');
```

override_subscribe_settings( )

The override_subscribe_settings attribute controls whether the subscribe_settings method values of the member are used, instead of the Grid default.

The override_subscribe_settings attribute can be specified explicitly. It is also set implicitly when subscribe_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for subscribe_settings. Set the parameter to "false" to inherit the Grid-level setting for subscribe_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_subscribe_settings value
my $override_subscribe_settings = $object->override_subscribe_settings( );
#Modify override_subscribe_settings value
$object->override_subscribe_settings("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP Network is used, instead of the Grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the upper-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_update_dns_on_lease_renewal
my $override_update_dns_on_lease_renewal=$network->override_update_dns_on_lease_renewal( );
#Modifying override_update_dns_on_lease_renewal
$network->override_update_dns_on_lease_renewal("true");
```

port_control_blackout_setting

Use this method to set or retrieve the port control blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when port_control_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->port_control_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->port_control_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get port_control_blackout_setting
my $port_control_blackout_setting = $network->port_control_blackout_setting();
#Modify port_control_blackout_setting
$network->port_control_blackout_setting($blackout);
```

pxe_lease_time( )

Use this method to set or retrieve the PXE lease time value of a DHCP Network Container object. Some hosts use PXE (Preboot Execution Environment) to boot remotely from a server. To better manage your IP resources, set a different lease time for PXE boot requests. You can configure the DHCP server to allocate an IP address with a shorter lease time to hosts that send PXE boot requests, so IP addresses are not leased longer than necessary. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, that the update is cached. Zero indicates that the update is not cached. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get PXE Lease Time
my $pxe_lease_time = $network_container->pxe_lease_time();
#Modify PXE Lease Time
$network_container->pxe_lease_time(1100);
#Un-override PXE Lease Time
$network_container->pxe_lease_time(undef);
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag at the network level.

If the flag is enabled, the leases are kept in the recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Parameter

Specify "true" to enable the recycle_leases flag or "false" to disable it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $network->recycle_leases();
#Modify recycle_leases
$network->recycle_leases("false");
```

remove_subnets( )

Use this method to set or retrieve the remove_subnets flag of a DHCP Network Container object.

You can remove the network, but keep all subnets under it if this flag is set to false. This flag is only intended as an option when removing DHCP Network Container objects. It is not retrieved or used for any other operation.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "false" to keep the subnets or "true" to remove them. The default value is undefined, which is to remove all subnets.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Set remove_subnets before submitting for removal
$network_container->remove_subnets("false");
#Remove the container keeping the subnets
$session->remove($network_container);
```

network_container( )

Use this method to set or retrieve the network container of a DHCP Network Container object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the IP address and netmask of a network in CIDR format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network container
my $network_container = $network->network_container();
#Modify network container
$network->network_container("50.0.0.0/8");
```

network_view( )

Use this method to set or retrieve the network view of the DHCP network container.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the network is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $network_container->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$network_container->network_view($nview);
```

next_available_network( )

Use this method to retrieve the next available `network(s)` in the network container. Note that to use this method, the object MUST be retrieved through a get or search call, or created with an add call.

Parameter

The method accepts the following parameters:

```
  cidr - (required) The CIDR of the requested networks. It must be a value between 1 and 32,
inclusive.
  requested_num - (optional) The number of networks requested. It must be a value between 1 and 20,
inclusive.
  excluded - (optional) aA reference to an array of networks to be excluded from the results.
```

Returns

This method returns the next available `network(s)` in the network container. If requested_num is not specified, a string with the next available network will be returned; otherwise, the method will return a reference to an array of networks.

A network cannot be returned as the next available network if it cannot be inserted; such as when any of the following conditions exist:

- It's parent network has a DHCP configuration assigned and therefore cannot be converted to a network container.

- It overlaps with an existing network or network container, regardless of whether the existing network has a greater or smaller CIDR than the requested CIDR.

- Its network address or broadcast address is used by a fixed address or a host configured for DHCP.

Example

```
# Retrieve a particular network
my @retrieved_objs = $session->get(
                          object   => "Infoblox::DHCP::NetworkContainer",
                          network  => "10.0.0.0/8"
);

$network = $retrieved_objs[0];

# Print the next available IPv6 network in the network container
print $network->next_available_network(cidr => 12) . "\n";

# This will retrieve the next 10 available networks and print the first one.
my $addressesref = $network->next_available_network(requested_num => 10, cidr => 12);
print @$addressesref[0] . "\n";

# This will retrieve the next 10 available networks and exclude two.
my $addressesref = $network->next_available_network(cidr => 12, requested_num => 10, excluded =>
['10.0.0.0/12']);
```

resize( )

Use this method to resize a network container. Note that to use this method, the object MUST be retrieved through a get or search call, or it must have been created with an add call.

Parameter

prefix - Required. The bitmask prefix length after resizing.

auto_create_reversezone - Optional. Boolean flag indicating whether or not to automatically create the reverse zone.

reason - Optional. The reason for resizing the network container in string format with a maximum of 256 bytes. Used when 'rir_organization' attribute has been defined.

send_rir_request - Optional. Boolean flag that indicates whether the appliance should send an API or email request for Regional Internet Registry (RIR). Used when 'rir_organization' attribute has been defined.

Returns

The method returns true when the operation succeeds, and returns false when the operation fails. When an operation fails, the error code and error message are reported in the Session object's `status_code()` and `status_detail()` attributes.

Example

```
#Get Network Container through the session
my @retrieved_objs = $session->get(
           object =>"Infoblox::DHCP::NetworkContainer" ,
           network => "20.0.0.0/8"
        );
my $network_container = $retrieved_objs[0];

# Expand a /24 network container to a /16 network container, inserting
# a corresponding reverese zone in the process.
my $response = $network_container->resize(
      prefix        => "16"
      auto_create_reversezone => "true"
) or die("Resize Network Container failed: ",
         $session->status_code() . ":" . $session->status_detail());
```

restart_if_needed( )

Use this method to set the flag that indicates whether DHCP service should be restarted on a member that is serving DHCP for the changed object referenced in a cloud API request.

Parameter

Specify true to restart the DHCP service.

Returns

None

Example

```
# Modify
$network->restart_if_needed('true');
```

rir( )

Use this method to retrieve the name of the Regional Internet Registry (RIR) that allocated this address space. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'RIPE' or 'NONE'.

Example

```
#Get rir
my $rir = $network_container->rir();
```

rir_organization( )

Use this method to set or retrieve the Regional Internet Registry (RIR) organization object.

Parameter

An Infoblox::Grid::RIR::Organization object.

You must enable support for RIR/SWIP at the Grid level before you can set attribute values. See Infoblox::Grid->enable_rir_swip() method.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_organization
my $rir_organization = $network_container->rir_organization();
#Modify rir_organization
$network_container->rir_organization($rir_org);
```

rir_registration_action( )

Use this method to set the registration action of Regional Internet Registry (RIR). This is a write-only attribute.

Parameter

Valid values are 'NONE', 'CREATE', 'MODIFY' or 'DELETE'.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set rir_registration_action
$network_container->rir_registration_action('CREATE');
```

rir_registration_status( )

Use this method to set or retrieve the registration status of Regional Internet Registry (RIR).

Parameter

The registration status of Regional Internet Registry (RIR), which can be 'REGISTERED' or 'NOT_REGISTERED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_registration_status
my $rir_registration_status = $network_container->rir_registration_status();
#Modify rir_registration_status
$network_container->rir_registration_status('NOT_REGISTERED');
```

last_rir_registration_update_sent( )

Use this method to retrieve the last registration update timestamp of Regional Internet Registry (RIR). This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_rir_registration_update_sent
my $last_rir_registration_update_sent = $network_container->last_rir_registration_update_sent();
```

last_rir_registration_update_status( )

Use this method to retrieve the last registration update status of Regional Internet Registry (RIR). This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_rir_registration_update_status
my $last_rir_registration_update_status = $network_container->last_rir_registration_update_status();
```

same_port_control_discovery_blackout( )

Use this method to set or retrieve the flag that enables using the same discovery blackout for port control blackout.

Parameter

Specify 'true' to use same discovery blackout for port control blackout or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $network_container->same_port_control_discovery_blackout();
# Modify attribute value
$network_container->same_port_control_discovery_blackout('true');
```

send_rir_request( )

Use this method to set the flag that indicates whether the appliance should send an API or email request for Regional Internet Registry (RIR). This is a write-only attribute.

Parameter

Specify "true" to set the send_rir_request flag or "false" to unset it.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set send_rir_request
$network_container->send_rir_request('true');
```

subscribe_settings( )

Use this method to set or retrieve the Cisco ISE subscribe settings.

Setting this method to a defined value implicitly sets the override_subscribe_settings method to "true". Setting the parameter to undefined causes the appliance to use the Cisco ISE endpoint default and automatically resets the override_subscribe_settings method to "false".

Note that when subscribe_settings is set to a defined value and override_subscribe_settings is set to "false", the last operation takes precedence. Thus the sequence $object->subscribe_settings($value); $object->override_subscribe_settings("false"); will set override_subscribe_settings to "false", and the sequence $object->override_subscribe_settings("false"); $object->subscribe_settings($value); will result in override_subscribe_settings="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::CiscoISE::SubscribeSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscribe_settings value
my $subscribe_settings = $object->subscribe_settings();
#Modify subscribe_settings value
$object->subscribe_settings($settings);
```

delete_reason( )

Use this method to specify the reason for deleting the Regional Internet Registry (RIR) registration request. This is a write-only attribute. This field is required only if 'rir_registration_action' is specified as 'DELETE'.

Parameter

The reason for deleting the RIR registration request in string format with a maximum of 256 bytes.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set delete_reason
$network_container->delete_reason('invalid');
```

unmanaged( )

Use this method to set or retrieve the network status, which indicates whether the network is unmanaged or not.

Parameter

Specify true to mark the network as unmanaged or false as managed.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get network status
$unmanaged = $network_container->unmanaged();
# Modify network status
$network_container->unmanaged('true');
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$network_container->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$network_container->update_dns_on_lease_renewal("true");
```

zone_associations( )

Use this method to set or retrieve the associated zone information.

Parameter

The valid value is an array reference that contains Infoblox::DNS::Zone object(s). The default value is an empty list. If the network container has a parent, it is possible to use the zone associations of the parent by setting the parameter to undef.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Examples

```
#Getting zone associations
my $zone_associations = $network_container->zone_associations();
my $zone1 = Infoblox::DNS::Zone->new(
      name     => "test1.com",
);
my $zone2 = Infoblox::DNS::Zone->new(
      name     => "test2.com",
   );
#Modifying zone_associations
$network_container->zone_associations([$zone1, $zone2]);
#Clear zone_assocations
$network_container->zone_associations([]);
##Remove the override for zone_associations
$network_container->zone_associations(undef)
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP Network Container object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
```

```
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP Network Container object

```
my $network_container = Infoblox::DHCP::NetworkContainer->new(
            network => "10.0.0.0/8",
            comment => "add network container",
             );

my $response = $session->add($network_container)
       or die("Add Network Container failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Network Container added successfully\n";

#Search for a specific Network Container

#Search the network container
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::NetworkContainer",
    network => '10\.0\.0\..*'
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search Network Container failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search Network Container found at least 1 matching entry\n";
```

#Get and modify a Network Container attribute

```
#Get Network Container through the session
my @retrieved_objs = $session->get(
           object =>"Infoblox::DHCP::NetworkContainer" ,
           network => "10.0.0.0/8"
        );
```

```
my $object = $retrieved_objs[0];
```

```
unless ($object) {
    die("Get Network Container object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Network Container found at least 1 matching entry\n";
```

#Modify one of the attributes of the specified Network Container object

```
$object->comment("modified comment"); #Apply the changes

$session->modify($object)
    or die("Modify Network Container attribute failed: ",
           $session->status_code() . ":" . $session->status_detail());

print "Network Container object modified successfully \n";
```

#Resize a network container

```
#Get Network through the session
my @retrieved_objs = $session->get(
    object =>"Infoblox::DHCP::NetworkContainer" ,
    network => "10.0.0.0/8"
);
my $object = $retrieved_objs[0];

#Resize
my $response = $object->resize(
    prefix => "16"
) or die("Resize Network Container failed: ",
    $session->status_code() . ":" . $session->status_detail());
```

#Remove a Network Container Object

```
 #Get Network Container object through the session
 my @retrieved_objs = $session->get(
           object  => "Infoblox::DHCP::NetworkContainer" ,
           network => "10.0.0.0"
       );

   my $object = $retrieved_objs[0];

   unless ($object) {
    die("Get Network Container object failed: ",
        $session->status_code() . ":" . $session->status_detail());
    }

print "Get Network Container object found at least 1 matching entry\n";
```

#Submit the object for removal

```
$session->remove($object)
    or die("Remove Network Container failed: ",
        $session->status_code() . ":" . $session->status_detail());

print "Network Container removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::NetworkTemplate - DHCP Network Template object

DESCRIPTION

You can use a template to create networks in a quick and consistent way. Networks created from a network template inherit all the properties defined in the network template, except for the comment and netmask if they are defined in the network.

CONSTRUCTOR

```
 my $network_template = Infoblox::DHCP::NetworkTemplate->new(
        name                            => $string,
#Required
        allow_any_netmask               => "true" | "false",
#Optional / Default is "false"
        authority                       => "true" | "false",
#Optional / Default is "false"
        auto_create_reversezone         => "true" | "false"
#Optional / Default is "false"
        bootfile                        => $filename | undef,
#Optional / Default is undefined
        bootserver                      => $ipv4addr | $fqdn | undef,
#Optional / Default is undefined
        comment                         => $string,
#Optional / Default is empty
        ddns_domainname                 => $string | undef,
#Optional / Default is undefined
        ddns_generate_hostname          => "true" | "false" | undef,
#Optional / Default is undefined
        ddns_update_fixed_addresses     => "true" | "false" | undef,
#Optional / Default is undefined
        ddns_server_always_updates      => "true" | "false",
#Optional / Default is "true"
        ddns_ttl                        => $num,
#Optional / Default is 0
        ddns_use_option81               => "true" | "false" | undef,
#Optional / Default is undefined
        deny_bootp                      => "true" | "false" | undef,
#Optional / Default undefined
        email_list                      => [ "admin\@test.com",...],
#Optional / Default is undefined
        enable_ddns                     => "true" | "false" | undef,
#Optional / Default is undefined
        enable_dhcp_thresholds          => "true" | "false",
#Optional / Default is undefined
        enable_email_warnings           => "true" | "false",
#Optional / Default is undefined
        enable_snmp_warnings            => "true" | "false",
#Optional / Default is undefined
        extattrs                        => { $string => $extattr, ... },
#Optional / Default is undefined
        extensible_attributes           => { $string => $string | $num, $string => [ $string | $num, ... ],
... }, #Required if 'rir_organization' attribute is defined

#Otherwise is optional
        fixed_address_templates         => [$FixedAddrTemplate1,$FixedAddrTemplate2,...]
#Optional / Default is empty
        high_water_mark                 => $number,
#Optional / Default is "95"
        high_water_mark_reset           => $number,
#Optional / Default is "95"
        ignore_dhcp_option_list_request => "true" | "false" | undef,
#Optional / Default is undefined
        lease_scavenge_time             => $number,
#Optional / Default is -1
        low_water_mark                  => $number,
#Optional / Default is "0"
        low_water_mark_reset            => $number,
#Optional / Default is "0"
        members                         => [$Member1,$Member2,...],
#Optional / Default is empty
        netmask                         => $netmask,
#Optional / Default is /8
        nextserver                      => $ipv4addr | $fqdn | undef,
#Optional / Default is undefined
        options                         => [$Option1,$Option2,...]
#Optional / Default is empty
        override_ddns_ttl               => "true" | "false",
#Optional / Default value is "false"
        override_ddns_domainname        => "true" | "false",
#Optional / Default value is "false"
        override_lease_scavenge_time    => "true" | "false",
```

```
#Optional / Default value is "false"
        override_update_dns_on_lease_renewal  => "true" | "false",
#Optional / Default value is "false"
        pxe_lease_time                => $num | undef,
#Optional / Default is undefined
        range_templates               => [$RangeTemplate1,$RangeTemplate2,...],
#Optional / Default is empty
        recycle_leases                => "true" | "false" | undef,
#Optional / Default is undefined
        rir_organization              => $rir_org,
#Optional / An Infoblox::Grid::RIR::Organization object
        rir_registration_action       => 'NONE' | 'CREATE',
#Optional / Default is 'NONE'
        rir_registration_status       => 'NOT_REGISTERED' | 'REGISTERED',
#Optional / Default is 'NOT_REGISTERED'
        send_rir_request              => 'true' | 'false',
#Optional / Default is 'false'
        update_dns_on_lease_renewal   => "true" | "false",
#Optional / Default value is "false"
        ipam_trap_settings             => $ipam_trap,
#Optional / An Infoblox::Grid::SNMP::IPAMTrap object
        override_ipam_trap_settings   => "true" | "false",
#Optional / Default value is "false"
        ipam_threshold_settings        => $ipam_threshold,
#Optional / An Infoblox::Grid::SNMP::IPAMThreshold object
        override_ipam_threshold_settings => "true" | "false",
#Optional / Default value is "false"
        ipam_email_addresses          => [$email1, $email2, ...],
#Optional / Default is an empty list
        override_ipam_email_addresses => "true" | "false",
#Optional / Default value is "false"
        logic_filters                 => [ $filter_name | $filter_obj, ...], # Optional / Default is
undefined
        override_logic_filters        => "true" | 'false",                  # Optional / Default value
is "false"
      );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a DHCP Network Template object.

Infoblox::Session->add( )

Use this method to add a network template object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $network_template = Infoblox::DHCP::NetworkTemplate->new(
       name             => "custom_network_template",
       allow_any_netmask => "true",
);

# Submit for adding network template
my $response = $session->add( $network_template );
```

Infoblox::Session->get( )

Use this method to retrieve the matching network template objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP Network template object:

 name - Required. The name of network template.
 extattrs     - Optional. A hash reference containing extensible attributes.
```

Example

```
 my  @result_array = $session->get(
      object  => "Infoblox::DHCP::NetworkTemplate" ,
      name    => "custom_network_template"
 );
```

Infoblox::Session->search( )

Use this method to retrieve all the matching network template objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific DHCP Network Template object:

 name    - Optional. The name of the network template (regular
           expression).
 comment - Optional. The comment of the network template (regular
           expression).
 extattrs     - Optional. A hash reference containing extensible attributes.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
my  @result_array = $session->search(
     object  => "Infoblox::DHCP::NetworkTemplate" ,
     name    => "custom_network_template"
 comment => ".*",
);

# search all Network Templates with a given extensible attribute 'Site'
my @retrieved_objs = $session->search(
  object => "Infoblox::DHCP::NetworkTemplate",
  extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify a network template object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify enable_ddns method.
$object->enable_ddns("true");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Get the object under the same name
my  @result_array = $session->get(

      object => "Infoblox::DHCP::NetworkTemplate" ,
      name   => "custom_network_template"
            );

# find the desired object from retrieved list.
my $desired_network_template = $result_array[0];

# Submit for removal
my $response = $session->remove( $desired_network_template );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP Network template object

allow_any_netmask( )

Use this method to set or retrieve the allow_any_netmask parameter of a DHCP network template object. If you set this parameter to "true", then the template allows any netmask. A user must specify a netmask when creating a network using this template. If you set this parameter to false, you must specify the "netmask" property for the network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the allow_any_netmask parameter or specify "false" if you want to specify a particular netmask. The default value is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get allow_any_netmask
my $allow_any_netmask = $network_template->allow_any_netmask()
# Modify allow_any_netmask
$network_template->allow_any_netmask("true");
```

authority( )

Use this method to set or retrieve the authority flag of a DHCP network template object. This flag specifies if a DHCP server is authoritative for the network.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the authority flag or "false" to deactivate/unset it. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get authority
my $authority = $network_template->authority()
# Modify authority
$network_template->authority("true");
```

auto_create_reversezone( )

Use this method to set or retrieve the auto_create_reversezone flag of a DHCP network template object. This flag indicates whether the appliance must automatically create the corresponding reverse zone.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to create a reverse zone automatically or "false" to disable the automatic creation of a reverse zone.The default value for this field is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get auto_create_reversezone
my $auto_create_reversezone = $network_template->auto_create_reversezone();
# Modify auto_create_reversezone
$network_template->auto_create_reversezone("true");
```

bootfile( )

Use this method to set or retrieve the bootfile attribute of a DHCP network template object. You can configure the DHCP server to support clients that use the boot file name option in their DHCPREQUEST messages. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::NetworkTemplate->bootserver() and Infoblox::DHCP::NetworkTemplate->nextserver().

Parameter

The name, in string format, of the file that the client must download. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get bootfile
my $bootfile = $network_template->bootfile();
# Modify bootfile
$network_template->bootfile("bootfile1");
#Un-override bootfile
$network_template->bootfile(undef);
```

bootserver( )

Use this method to set or retrieve the boot server attribute of a DHCP network template object. You can specify the name of the boot server on which the boot file is stored. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::NetworkTemplate->bootfile() and Infoblox::DHCP::NetworkTemplate->nextserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get bootserver
my $bootserver = $network_template->bootserver();
# Modify bootserver
$network_template->bootserver("abc.domain.com");
#Un-override bootserver
$network_template->bootserver(undef);
```

comment( )

Use this method to set or retrieve a descriptive comment about a DHCP network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network template in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $network_template->comment();
# Modify comment
$network_template->comment("add a network");
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP Network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_dddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $network_template->ddns_domainname();
#Modify ddns_domainname
$network_template->ddns_domainname("test_domain.com");
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a DHCP network template object. Set this flag to allow only the DHCP server to generate a host name. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to generate hostname or "false" to deactivate/unset it. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_generate_hostname
my $ddns_generate_hostname = $network_template->ddns_generate_hostname()
# Modify ddns_generate_hostname
$network_template->ddns_generate_hostname("true");
#Un-override
$network_template->ddns_generate_hostname(undef);
```

ddns_update_fixed_addresses( )

Use this method to set or retrieve the ddns_update_fixed_addresses flag of a DHCP network template object. By default, the DHCP server does not update DNS when it allocates a fixed address to a client. You can configure the DHCP server to update the A and PTR records of a client with a fixed address. When this feature is enabled and the DHCP server adds A and PTR records for a fixed address, the DHCP server never discards the records. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to update DNS when it allocates a fixed address to a client or "false" to deactivate/unset it. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_update_fixed_addresses
my $ddns_update_fixed_addresses= $network_template->ddns_update_fixed_addresses()
# Modify ddns_update_fixed_addresses
$network_template->ddns_update_fixed_addresses("true");
#Un-override
$network_template->ddns_update_fixed_addresses(undef);
```

ddns_server_always_updates( )

Use this method to set or retrieve the ddns_server_always_updates flag of a DHCP network template object. Set this flag to allow the DHCP server only to update DNS, regardless of the requests from DHCP clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set this flag and allow the DHCP server only to update DNS or "false" to deactivate/unset the flag. The default value is true.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_server_always_updates
my $ddns_server_always_updates = $network_template->ddns_server_always_updates()
# Modify ddns_server_always_updates
$network_template->ddns_server_always_updates("true");
```

ddns_ttl( )

Use this method to set or retrieve the DNS update Time to Live (TTL) value of a DHCP network template object. The TTL value indicates the number of seconds the Infoblox appliance caches a DDNS update.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_dddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, that the update is cached. Zero indicates that the update should not be cached. The default value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get DNS Update ttl
my $dns_ttl = $network_template->ddns_ttl();
#Modify DNS Update ttl
$network_template->ddns_ttl(1200);
```

ddns_use_option81( )

Use this method to set or retrieve the ddns_use_option81 flag of a DHCP network template object. Enable this method to define the settings for option 81 at the network template level. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to enable support for option 81 or "false" to disable support. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_use_option81
my $ddns_use_option81 = $network_template->ddns_use_option81()
# Modify ddns_use_option81
```

```
$network_template->ddns_use_option81("true");
# un-override ddns_use_option81
$network_template->ddns_use_option81(undef);
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $network->deny_bootp();
#Modify deny_bootp
$network->deny_bootp("true");
```

email_list( )

Use this method to set or retrieve the e-mail lists to which the appliance sends threshold e-mail messages.

If you enter e-mail addresses in the email_list, then the appliance sends DHCP threshold alarms to the e-mail addresses.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get email_list
my @email_list = $network_template->email_list();
#Modify email_list
$network_template->email_list( [ "admin\@test.com" ] );
```

enable_ddns( )

Use this method to set or retrieve the dynamic DNS updates flag of a DHCP network template object. The DHCP server can send DDNS updates to DNS servers in the same grid and to external DNS servers. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the dynamic DNS updates flag or "false" to deactivate/unset it. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ddns
my $enable_ddns = $network_template->enable_ddns()
# Modify enable_ddns
$network_template->enable_ddns("true");
# Un-override enable_ddns
$network_template->enable_ddns(undef);
```

enable_dhcp_thresholds( )

Use this method to set or retrieve the DHCP thresholds of a network template object. These thresholds are the high and low watermarks. If DHCP range usage goes above or below these percentage values, the Infoblox appliance generates a syslog message and sends an SNMP notification.

Enable this flag to set DHCP threshold values.

Parameter

Specify "true" to set the enable_dhcp_thresholds flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp_thresholds
my $enable_dhcp_thresholds = $network_template->enable_dhcp_thresholds();
#Modify enable_dhcp_thresholds
$network_template->enable_dhcp_thresholds("false");
```

enable_email_warnings( )

Use this method to send DHCP thresholds warnings through e-mail.

Enable this flag if you want the appliance to send DHCP threshold warnings to the "email_list" provided when DHCP threshold is enabled.

Parameter

+Specify "true" to set the enable_email_warnings flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_email_warnings
my $enable_email_warnings = $network_template->enable_email_warnings();
#Modify enable_email_warnings
$network_template->enable_email_warnings("false");
```

enable_snmp_warnings( )

Use this method to send DHCP threshold warnings through SNMP.

If the flag is enabled, then the appliance sends DHCP threshold warnings through SNMP messages when DHCP threshold is enabled.

Parameter

Specify "true" to set the enable_snmp_warnings flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_snmp_warnings
my $enable_snmp_warnings = $network_template->enable_snmp_warnings();
#Modify enable_snmp_warnings
$network_template->enable_snmp_warnings("false");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Network Template object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr

objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $network_template->extattrs();
#Modify extattrs
$network_template->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a Network Template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $network_template->extensible_attributes();
#Modify extensible attributes
$network_template->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

fixed_address_templates( )

Use this method to set or retrieve the fixed address template assigned to this network template object. When you create a network based on a network template object with a fixed address template, the fixed addresses are created based on the associated fixed address template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference of Infoblox::DHCP::Template objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get fixed_address_templates
my $fixed_address_templates = $network_template->fixed_address_templates();
# Modify fixed_address_templates
my $tmpl = Infoblox::DHCP::Template->new(
   name => "custom_fixed_address_template"
);
$network_template->fixed_address_templates([$tmpl]);
```

high_water_mark( )

Use this method to set the percentage value for DHCP range usage above which the Infoblox appliance generates a syslog message and sends a warning.

When the percent of allocated addresses in a DHCP range exceeds the high_water_mark, the appliance generates a syslog message and sends a warning.

Parameter

The valid value is in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high_water_mark
my $high_water_mark = $network_template->high_water_mark();
#Modify high_water_mark
$network_template->high_water_mark("80");
```

high_water_mark_reset( )

Use this method to set or retrieve the high_water_mark_reset value. If the percentage of allocated addresses drops below this value, the corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The high watermark reset value must be lower than the high water mark value. The default value is 95.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get high_water_mark_reset
my $high_water_mark_reset = $network_template->high_water_mark_reset();
#Modify high_water_mark_reset
$network_template->high_water_mark_reset(70);
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a DHCP network template object. Set this flag to ignore option lists requested by clients and return all defined options at the network template level.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate/unset it. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $network_template->ignore_dhcp_option_list_request();
# Modify ignore_dhcp_option_list_request
$network_template->ignore_dhcp_option_list_request("false");
# Un-override ignore_dhcp_option_list_request
$network_template->ignore_dhcp_option_list_request(undef);
```

ipam_email_addresses( )

Use this method to set or retrieve a list of IPAM Utilization email addresses.

Setting this method to a defined value implicitly sets the override_ipam_email_addresses method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_email_addresses attribute to "false".

Note that when ipam_email_addresses is set to a defined value and override_ipam_email_addresses is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_email_addresses(['admin@infoblox.com']); $object->override_ipam_email_addresses("false"); will set override_ipam_email_addresses to "false", and the sequence $object->override_ipam_email_addresses("false"); $object->ipam_email_addresses(['admin@infoblox.com']); will result in override_ipam_email_addresses="true".

Parameter

Valid value is an array reference that contains email addresses in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_email_addresses
my $ipam_email_addresses = $network_template->ipam_email_addresses();
#Modify ipam_email_addresses
$network_template->ipam_email_addresses($ipam_email_addresses);
```

ipam_trap_settings( )

Use this method to set or retrieve IPAM Utilization SNMP Trap settings.

Setting this method to a defined value implicitly sets the override_ipam_trap_settings method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_trap_settings attribute to "false".

Note that when ipam_trap_settings is set to a defined value and override_ipam_trap_settings is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_trap_settings($ipam_trap); $object->override_ipam_trap_settings("false"); will set override_ipam_trap_settings to "false", and the sequence $object->override_ipam_trap_settings("false"); $object->ipam_trap_settings($ipam_trap); will result in override_ipam_trap_settings="true".

Parameter

Valid value is an Infoblox::Grid::SNMP::IPAMTrap object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_trap_settings
my $ipam_trap_settings = $network_template->ipam_trap_settings();
#Modify ipam_trap_settings
$network_template->ipam_trap_settings($ipam_trap_settings);
```

ipam_threshold_settings( )

Use this method to set or retrieve IPAM Utilization SNMP Threshold settings.

Setting this method to a defined value implicitly sets the override_ipam_threshold_settings method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_ipam_threshold_settings attribute to "false".

Note that when ipam_threshold_settings is set to a defined value and override_ipam_threshold_settings is set to "false", the last operation takes precedence. Thus the sequence $object->ipam_threshold_settings($ipam_threshold_settings); $object->override_ipam_trap_settings("false"); will set override_ipam_threshold_settings to "false", and the sequence $object->override_ipam_threshold_settings("false"); $object->ipam_threshold_settings($ipam_threshold_settings); will result in override_ipam_threshold_settings="true".

Parameter

Valid value is an Infoblox::Grid::SNMP::IPAMThreashold object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipam_threshold_settings
my $ipam_threshold_settings = $network_template->ipam_threshold_settings();
#Modify ipam_threshold_settings
$network_template->ipam_threshold_settings($ipam_threshold_settings);
```

lease_scavenge_time( )

Use this method to set or retrieve the lease_scavenge_time value of a Network Template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_lease_scavenge_time method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_lease_scavenge_time attribute to "false".

Note that when lease_scavenge_time is set to a defined value and override_lease_scavenge_time is set to "false", the last operation takes precedence. Thus the sequence $object->lease_scavenge_time(604800); $object->override_lease_scavenge_time("false"); will set override_lease_scavenge_time to "false", and the sequence $object->override_lease_scavenge_time("false"); $object->lease_scavenge_time(604800); will result in override_lease_scavenge_time="true".

Parameter

An integer that specifies the period of time, in seconds, that free and backup leases remain in the database before they are automatically deleted. To disable lease scavenging, set the parameter to -1. The minimum positive value must be greater than 86400 seconds (1 day). The default value of this parameter is -1, which means that lease scavenging is disabled.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lease_scavenge_time
my $lease_scavenge = $network_template->lease_scavenge_time();
#Modify lease_scavenge_time
$network_template->lease_scavenge_time(30 * 24 * 60 * 60);
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Network Template.

Filters are used to screen address assignments in the DHCP Network Template if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $network_template->logic_filters();
#Modify logic_filters
$network_template->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an
Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

low_water_mark( )

Use this method to set the percentage value for DHCP range usage below which the Infoblox appliance generates a syslog message and

sends a warning.

When the percent of allocated addresses in a DHCP range goes below the low_water_mark, the appliance generates a syslog message and sends a warning.

Parameter

The valid value is in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low_water_mark
my $low_water_mark = $network_template->low_water_mark();
#Modify low_water_mark
$network_template->low_water_mark("10");
```

low_water_mark_reset( )

Use this method to set or retrieve the low_water_mark_reset value. If the percentage of allocated addresses exceeds this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The low watermark reset value must be higher than the low watermark value. The default low watermark reset number is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get low_water_mark_reset
my $low_water_mark_reset = $network_template->low_water_mark_reset();
#Modify low_water_mark_reset
$network_template->low_water_mark_reset(10);
```

members( )

Use this method to set or retrieve the member or Microsoft (r) server that serves DHCP for the network created from the network template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Member or Infoblox::DHCP::MSServer objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $member1 = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
);

# Get members
my $members = $network_template->members();
# Modify members
$network_template->members([$member1]);
```

name( )

Use this method to set or retrieve the description of the name of the DHCP network template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the network template in string format with a maximum of 64 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $network_template->name();
#Modify name
$network_template->name("custom_network_template");
```

netmask( )

Use this method to set or retrieve the netmask attribute of a DHCP network template object. If "allow_any_netmask" is set to "false", then this attribute must be specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A valid subnet mask. The default value is "255.0.0.0".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get netmask
my $netmask = $network_template->netmask();
#Set netmask
$nework_template->allow_any_netmask( "false" );
my $netmask = $network_template->netmask("255.0.0.0");
```

nextserver( )

Use this method to set or retrieve the nextserver attribute of a DHCP network template object. You can specify the name and/or IP address of the next server to which the host needs to connect in order to boot. This setting overrides the upper-level settings. The default value is undefined which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::NetworkTemplate->bootfile() and Infoblox::DHCP::NetworkTemplate->bootserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get nextserver
my $nextserver = $network_template->nextserver();
# Modify nextserver
$network_template->nextserver("blue.domain.com");
#Un-override nextserver
$network_template->nextserver(undef);
```

options( )

Use this method to set or retrieve the options value of a network template object. DHCP options provide network configuration settings and various services available on the network for DHCP. This setting overrides the upper-level setting. The default value is undefined which indicates that this attribute inherit the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $network_template->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name  => "lease-time",
    value => 50
);

$network_template->options([$option1]);
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP network template object is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$network_template->override_ddns_domainname( );
#Modifying override_ddns_domainname
$network_template->override_ddns_domainname("true");
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the DHCP network template object is used, instead of the grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_ttl. Set the parameter to "false" to inherit the grid-level setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_ttl
my $override_ddns_ttl=$network_template->override_ddns_ttl( );
#Modifying override_ddns_ttl
$network_template->override_ddns_ttl("true");
```

override_ipam_email_addresses( )

The override_ipam_email_addresses controls whether the ipam_email_addresses in the DHCP network template is used, instead of the upper-level default.

The override_ipam_email_addresses can be specified explicitly. It is also set implicitly when ipam_email_addresses is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_email_addresses. Set the parameter to "false" to inherit the upper-level setting for ipam_email_addresses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network_template->override_ipam_email_addresses();
#Modifying attribute value
$network_template->override_ipam_email_addresses('true');
```

override_ipam_threshold_settings( )

The override_ipam_threshold_settings controls whether the ipam_threshold_settings in the DHCP network template is used, instead of the upper-level default.

The override_ipam_threshold_settings can be specified explicitly. It is also set implicitly when ipam_threshold_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_threshold_settings. Set the parameter to "false" to inherit the upper-level setting for ipam_threshold_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network_template->override_ipam_threshold_settings();
#Modifying attribute value
$network_template->override_ipam_threshold_settings('true');
```

override_ipam_trap_settings( )

The override_ipam_trap_settings controls whether the ipam_trap_settings in the DHCP network template is used, instead of the upper-level default.

The override_ipam_trap_settings can be specified explicitly. It is also set implicitly when ipam_trap_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipam_trap_settings. Set the parameter to "false" to inherit the upper-level setting for ipam_trap_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$network_template->override_ipam_trap_settings();
#Modifying attribute value
$network_template->override_ipam_trap_settings('true');
```

override_lease_scavenge_time( )

The override_lease_scavenge_time attribute controls whether the lease_scavenge_time value in the network template is used, instead of the upper-level default.

The override_lease_scavenge_time attribute can be specified explicitly. It is also set implicitly when lease_scavenge_time is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for lease_scavenge_time. Set the parameter to "false" to inherit the setting for lease_scavenge_time from the upper level.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_lease_scavenge_time
my $override_lease_scavenge_time=$network_template->override_lease_scavenge_time( );
#Modifying override_lease_scavenge_time
$network_template->override_lease_scavenge_time("true");
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value of the DHCP Network Template is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$network_template->override_logic_filters( );
#Modifying override_logic_filters
$network_template->override_logic_filters("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP network template object is used, instead of the grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_update_dns_on_lease_renewal
my $override_update_dns_on_lease_renewal=$network_template->override_update_dns_on_lease_renewal(
);
#Modifying override_update_dns_on_lease_renewal
$network_template->override_update_dns_on_lease_renewal("true");
```

pxe_lease_time( )

Use this method to set or retrieve the PXE lease time value of a DHCP network template object. Some hosts use PXE (Preboot Execution Environment) to boot remotely from a server. To better manage your IP resources, set a different lease time for PXE boot requests. You can configure the DHCP server to allocate an IP address with a shorter lease time to hosts that send PXE boot requests, so IP addresses are not leased longer than necessary. This setting overrides the upper-level settings. The default value is undefined, which indicates that this attribute inherits the upper-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, that the update is cached. Zero indicates that the update should not be cached. The default value is undefined

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get PXE Lease Time
my $pxe_lease_time = $network_template->pxe_lease_time();
#Modify PXE Lease Time
$network_template->pxe_lease_time(1100);
#Un-override PXE Lease Time
$network_template->pxe_lease_time(undef);
```

range_templates( )

Use this method to set or retrieve the IP address range template assigned to this network template object. When you create a network based on a network template object with a range template, the IP address ranges are created based on the associated IP address range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference of Infoblox::DHCP::Template objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_templates
my $range_templates = $network_template->range_templates();
#Modify range_templates
my $tmpl = Infoblox::DHCP::Template->new(
   name => "custom_range_template"
);
$network_template->range_templates([ $tmpl ]);
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$network_template->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$network_template->update_dns_on_lease_renewal("true");
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag at the network template level.

If the flag is enabled, the leases are kept in the recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Parameter

Specify "true" to enable the recycle_leases flag or "false" to disable it. The default value is undefined, which indicates that this attribute inherit the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $network_template->recycle_leases();
#Modify recycle_leases
$network_template->recycle_leases("false");
```

rir( )

Use this method to retrieve the name of the Regional Internet Registry (RIR) that allocated this address space. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value that can be 'RIPE' or 'NONE'.

Example

```
#Get rir
my $rir = $network_template->rir();
```

rir_organization( )

Use this method to set or retrieve the Regional Internet Registry (RIR) organization object.

Parameter

An Infoblox::Grid::RIR::Organization object.

You must enable support for RIR/SWIP at the Grid level before you can set attribute values. See Infoblox::Grid->enable_rir_swip() method.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_organization
my $rir_organization = $network_template->rir_organization();
#Modify rir_organization
$network_template->rir_organization($rir_org);
```

rir_registration_action( )

Use this method to set or retrieve the registration action of Regional Internet Registry (RIR).

Parameter

Valid values are 'NONE', 'CREATE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_registration_action
my $rir_registration_action = $network_template->rir_registration_action();
#Modify rir_registration_action
$network_template->rir_registration_action('CREATE');
```

rir_registration_status( )

Use this method to set or retrieve the registration status of Regional Internet Registry (RIR).

Parameter

The registration status of Regional Internet Registry (RIR), which can be 'REGISTERED' or 'NOT_REGISTERED'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rir_registration_status
my $rir_registration_status = $network_template->rir_registration_status();
#Modify rir_registration_status
$network_template->rir_registration_status('NOT_REGISTERED');
```

send_rir_request( )

Use this method to set or retrieve the flag that indicates whether the appliance should send an API or email request for Regional Internet Registry (RIR).

Parameter

Specify "true" to set the send_rir_request flag or "false" to unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get send_rir_request
my $send_rir_request = $network_template->send_rir_request();
#Modify send_rir_request
$network_template->send_rir_request('true');
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. Also, this sample code includes error handling for the operations.

#Preparation prior to a DHCP network template insertion

```
#PROGRAM STARTS: Include all the modules that will be used

use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $host_ip = "192.168.1.2";
my $host_name = "infoblox.localdomain";

my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $memberdhcp = Infoblox::DHCP::Member->new(
            name     => $host_name,
            ipv4addr => $host_ip
           );
```

#Add network template object

```
#Create a DHCP Network template object

my $network_template = Infoblox::DHCP::NetworkTemplate->new(
                               name                    => "custom_network_template",
                               netmask                 => "255.0.0.0",
                               comment                 => "add network template",
                               members                 => [ $memberdhcp ],
                               authority               => "true",
                               enable_ddns             => "true",
                               pxe_lease_time          => "3600",
                               bootserver              => "someserver.com",
                               nextserver              => "3.3.3.3",
                               bootfile                => "bootfile.com",
                               auto_create_reversezone => "true",
                               );

my $response = $session->add($network_template)
       or die("Add Network template failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Network template added successfully\n";
```

#Get and modify a network template attribute

```
#Get Network template through the session
my  @retrieved_objs = $session->get(
```

```
            object => "Infoblox::DHCP::NetworkTemplate",
            name   => "custom_network_template"
        );

 my $object = $retrieved_objs[0];

 unless ($object) {
     die("Get Network template object failed: ",
         $session->status_code() . ":" . $session->status_detail());
 }
 print "Get Network template found at least 1 matching entry\n";
```

#Search a network template attribute

```
 #Search Network template through the session
 my  @retrieved_objs = $session->search(
            object => "Infoblox::DHCP::NetworkTemplate",
            name   => "custom_network_template"
        );

 my $object = $retrieved_objs[0];

 unless ($object) {
     die("Search Network template object failed: ",
         $session->status_code() . ":" . $session->status_detail());
 }
 print "Search Network template found at least 1 matching entry\n";

 #Modify attributes of the specified Network Template

 $object->enable_ddns("true"); #Apply the changes

 #Un-override bootfile
 $object->bootfile(undef);

 #Un-override bootserver
 $object->bootserver(undef);

 #Un-override nextserver
 $object->nextserver(undef);

 $session->modify($object)
     or die("Modify Network template attribute failed: ",
            $session->status_code() . ":" . $session->status_detail());

 print "Network template object modified successfully \n";
```

#Remove a network template object

```
 #Get Network Template object through the session

  my @retrieved_objs = $session->get(
            object  => "Infoblox::DHCP::NetworkTemplate",
            name    => "custom_network_template"
       );

    my $object = $retrieved_objs[0];

    unless ($object) {
     die("Get Network Template object failed: ",
         $session->status_code() . ":" . $session->status_detail());
     }

 print "Get Network Template object found at least 1 matching entry\n";

 #Submit the object for removal

 $session->remove($object)
     or die("Remove Network Template failed: ",
         $session->status_code() . ":" . $session->status_detail());

 print "Network Template removed successfully \n";

 ####PROGRAM ENDS####

NAME

Infoblox::DHCP::NetworkUser - a DHCP Network User object.

DESCRIPTION

The DHCP Network User provides information about Active Directory users such as user's session at a specific IP address, domain, logon and logoff timestamps.

CONSTRUCTOR

```
my $network_user = Infoblox::DHCP::NetworkUser->new(
   address           => $ipaddr,     # Required
   domainame         => $str,        # Required
   first_seen_time   => $epoch,      # Required
   name              => $str,        # Required
   network_view      => $view_name,  # Required
   logon_id          => $str,        # Required
   guid              => $str,        # Required
   logout_time       => $epoch,      # Optional
   last_seen_time    => $epoch,      # Optional
);
```

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a DHCP Network User object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#construct an object
my $network_user = Infoblox::DHCP::NetworkUser->new(
   address      => '10.1.1.1',
   domainame    => 'AD-7',
   first_seen_time   => 1234567,
```

```
    name         => 'user1',
    network_view => $dhcp_view,
    logon_id     => '10',
    guid         => '15',
);

#submit for addition
my $response = $session->add($network_user);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

 address      - Optional. A DHCP Network User address.
 domainname   - Optional. A DHCP Network User domain name.
 guid         - Optional. A DHCP Network User group identifier.
 logon_id     - Optional. A DHCP Network User logon identifier.
 name         - Optional. A DHCP Network User name.
 network_view - Optional. A DHCP View object or a string which contains a DHCP View name.
 parent       - Optional. A DHCP or DNS object associated with the network user. Note that object
should be retrieved from the server.
 user_status  - Optional. A DHCP Network User status.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::DHCP::NetworkUser',
    name   => 'user.*',
);

my @retrieved_objs = $session->get(
    object => 'Infoblox::DHCP::NetworkUser',
    parent => $dhcp_range,
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the comment
$network_user->name('user2');
#Submit modification
my $response = $session->modify($network_user);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => 'Infoblox::DHCP::NetworkUser',
    name   => 'user1',
);
#Find the desired object from the retrieved list.
my $desired_user = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove($desired_user);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

 address      - Optional. A DHCP Network User address.
 domainname   - Optional. A DHCP Network User domain name.
```

```
  guid         - Optional. A DHCP Network User group identifier.
  logon_id     - Optional. A DHCP Network User logon identifier.
  name         - Optional. A DHCP Network User name.
  network_view - Optional. A DHCP View object or a string which contains a DHCP View name.
  parent       - Optional. A DHCP or DNS object associated with the network user. Note that object
should be retrieved from the server.
  user_status  - Optional. A DHCP Network User status.
```

Example

```
my @retrieved_objs = $session->search(
    object => 'Infoblox::DHCP::NetworkUser',
    name   => 'user.*',
);
```

METHODS

address( )

Use this method to set or retrieve the DHCP Network User address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an IPv4 or IPv6 address.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address
my $address = $network_user->address();
#Modify address
$network_user->address('10.10.10.10');
```

address_object( )

Use this method to retrieve the DHCP Network User address IPAM object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::IPAM::Address object.

Example

```
#Get address_object
my $address_object = $network_user->address_object();
```

data_source( )

Use this method to retrieve the DHCP Network User data source. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value. The valid return values are 'API', 'MS_SERVER' and 'CISCO_ISE'.

Example

```
#Get data_source
my $data_source = $network_user->data_source();
```

data_source_ip( )

Use this method to retrieve the DHCP Network User endpoint data source IP address or FQDN. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get data_source_ip
my $data_source_ip = $network_user->data_source_ip();
```

domainname( )

Use this method to set or retrieve the DHCP Network User domain name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired domain name in string format.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get domainname
my $domainname = $network_user->domainname();
#Modify domainname
$network_user->domainname('DOMAIN');
```

guid( )

Use this method to set or retrieve the DHCP Network User group identifier.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired group identifier in string format.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get guid
my $guid = $network_user->guid();
#Modify guid
$network_user->guid('10');
```

last_seen_time( )

Use this method to set or retrieve the DHCP Network User last active timestamp.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is the number of seconds that have elapsed since January 1st, 1970 UTC.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get last_seen_time
my $last_seen_time = $network_user->last_seen_time();
#Modify last_seen_time
$network_user->last_seen_time(1234567);
```

last_updated_time( )

Use this method to retrieve the DHCP Network User last updated timestamp. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get last_updated_time
my $last_updated_time = $network_user->last_updated_time();
```

first_seen_time( )

Use this method to set or retrieve the DHCP Network User first seen timestamp.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is the number of seconds that have elapsed since January 1st, 1970 UTC.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get first_seen_time
my $first_seen_time = $network_user->first_seen_time();
#Modify first_seen_time
$network_user->first_seen_time(1234567);
```

logon_id( )

Use this method to set or retrieve the DHCP Network User logon identifier.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired logon identifier in string format.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logon_id
my $logon_id = $network_user->logon_id();
#Modify logon_id
$network_user->logon_id('10');
```

logout_time( )

Use this method to set or retrieve the DHCP Network User logout timestamp.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is the number of seconds that have elapsed since January 1st, 1970 UTC.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logout_time
my $logout_time = $network_user->logout_time();
#Modify logout_time
$network_user->logout_time(1234567);
```

name( )

Use this method to set or retrieve the DHCP Network User name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired name in string format.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $network_user->name();
#Modify name
$network_user->name('user1');
```

network( )

Use this method to retrieve the DHCP Network User associated with the DHCP Network object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are Infoblox::DHCP::Network and Infoblox::DHCP::IPv6Network objects.

Example

```
#Get network
my $network = $network_user->network();
```

network_view( )

Use this method to set or retrieve the DHCP Network User associated with the DHCP View object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a desired DHCP View name in string format.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation

fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network_view
my $network_view = $network_user->network_view();
#Modify network_view
$network_user->network_view('internal');
```

user_status( )

Use this method to set or retrieve the DHCP Network User status. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return values are 'ACTIVE', 'LOGOUT' and 'TIMEOUT'.

Example

```
#Get user_status
my $user_status = $network_user->user_status();
```

Infoblox::DHCP::Option - DHCP Option object.

DESCRIPTION

An Option sets the value of a DHCP option that has been defined in an option space. DHCP options describe network configuration settings and various services available on the network. These options occur as variable-length fields at the end of DHCP messages.

CONSTRUCTOR

```
 my $option = Infoblox::DHCP::Option->new(
     value        => $num | $string |"true"|"false", #Required
     name         => $string,                        #Optional - One of name or num must be specified /
Default is undefined
     num          => $num,                           #Optional - One of name or num must be specified /
Default is undefined
     vendor_class => $string,                        #Optional / Default Option Space name is "DHCP"
 );
```

Note that in a future NIOS version 'num' will become mandatory and 'name' will become optional.

MODULE METHODS

The following functions can be applied to a DHCP Option object.

Infoblox::Grid::DHCP->options( )

Use this function to specify DHCP options at the grid level on the Infoblox appliance. See Infoblox::Grid::DHCP->options() for parameters and return values.

Example

```
       #Construct a DHCP Option object
       my $option1 = Infoblox::DHCP::Option->new(
                     name  => "lease-time",
                     value => "50"
       );
       # Configure a DHCP option for a grid
       my $response = $Grid_DHCP->options([$option1]);
```

Infoblox::Grid::Member::DHCP->options( )

Use this function to specify DHCP options at the grid member level on the Infoblox appliance. See Infoblox::Grid::Member::DHCP-

>options() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option2 = Infoblox::DHCP::Option->new(
              name  => "domain-name",
              value => "domainname.com"
);
# Configure a DHCP option for a grid member
my $response = $Grid_Member_DHCP->options([$option2]);
```

Infoblox::DHCP::Network->options( )

Use this function to specify DHCP options at the network level on the Infoblox appliance. See Infoblox::DHCP::Network->options() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option3 = Infoblox::DHCP::Option->new(
              name  => "broadcast",
              value => "255.0.0.0"
);
# Configure a DHCP option for a network
my $response = $Network_DHCP->options([$option3]);
```

Infoblox::DHCP::NetworkTemplate->options( )

Use this function to specify DHCP options at the network template level on the Infoblox appliance. See Infoblox::DHCP::NetworkTemplate->options() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option4 = Infoblox::DHCP::Option->new(
              name  => "broadcast",
              value => "2"
);
#Construct another DHCP Option object
my $option5 = Infoblox::DHCP::Option->new(
              name  => "routers",
              value => "1,2"
);
# Configure a DHCP options for a network template
my $response = $Network_Template_DHCP->options([$option4,$option5]);
```

Infoblox::DHCP::SharedNetwork->options( )

Use this function to specify DHCP options at the shared network level on the Infoblox appliance. See Infoblox::DHCP::SharedNetwork->options() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option6 = Infoblox::DHCP::Option->new(
              name  => "subnet-mask",
              value => "255.255.0.0"
);
# Configure a DHCP option for a shared network
my $response = $Shared_Network_DHCP->options([$option6]);
```

Infoblox::DHCP::FixedAddr->options( )

Use this function to specify DHCP options at the fixed address level on the Infoblox appliance. See Infoblox::DHCP::FixedAddr->options() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option7 = Infoblox::DHCP::Option->new(
              name  => "host-name",
              value => "host1.com"
);
# Configure a DHCP option for a fixed address
my $response = $Fixed_Address_DHCP->options([$option7]);
```

Infoblox::DHCP::FixedAddrTemplate->options( )

Use this function to specify DHCP options at the fixed address template level on the Infoblox appliance. See Infoblox::DHCP::FixedAddrTemplate->options() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option8 = Infoblox::DHCP::Option->new(
              name  => "broadcast",
              value => "2"
);
#Construct another DHCP Option object
my $option9 = Infoblox::DHCP::Option->new(
              name  => "routers",
              value => "1,2"
);
# Configure a DHCP options for a fixed address template
my $response = $Fixed_Address_Template_DHCP->options([$option8,$option9]);
```

Infoblox::DHCP::Range->options( )

Use this function to specify DHCP options at the DHCP range level on the Infoblox appliance. See Infoblox::DHCP::Range->options() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option10 = Infoblox::DHCP::Option->new(
              name  => "swap-server",
              value => "1.1.1.1"
);
# Configure a DHCP option for a DHCP range
my $response = $DHCP_Range->options([$option10]);
```

Infoblox::DHCP::RangeTemplate->options( )

Use this function to specify DHCP options at the range template level on the Infoblox appliance. See Infoblox::DHCP::RangeTemplate->options() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option11 = Infoblox::DHCP::Option->new(
              name  => "broadcast",
              value => "2"
);
#Construct another DHCP Option object
my $option12 = Infoblox::DHCP::Option->new(
              name  => "routers",
              value => "1,2"
);
# Configure a DHCP options for a range template
my $response = $Range_Template_DHCP->options([$option11,$option12]);
```

Infoblox::DHCP::Filter::Option->option_list( )

Use this function to specify DHCP options at the filter level on the Infoblox appliance. See Infoblox::DHCP::Filter::Option->option_list() for parameters and return values.

Example

```
#Construct a DHCP Option object
my $option13 = Infoblox::DHCP::Option->new(
              name  => "pop-server",
              value => "10.10.10.10"
);
# Configure a DHCP Option for a filter
my $response = $Filter_Option->option_list([$option13]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP option.

name( )

Use this method to set or retrieve the name of the DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the name of the DHCP option in string format. Valid values are

```
  "subnet-mask",                              - DHCP Option   1              - ip-address
  "time-offset",                              - DHCP Option   2              - 32-bit signed integer
  "routers",                                  - DHCP Option   3              - array of ip-address |
array of offsets (for templates)
  "time-servers",                             - DHCP Option   4              - array of ip-address
  "ien116-name-servers",                      - DHCP Option   5              - array of ip-address
  "domain-name-servers",                      - DHCP Option   6              - array of ip-address
  "log-servers",                              - DHCP Option   7              - array of ip-address
  "cookie-servers",                           - DHCP Option   8              - array of ip-address
  "lpr-servers",                              - DHCP Option   9              - array of ip-address
  "impress-servers",                          - DHCP Option  10              - array of ip-address
  "resource-location-servers",                - DHCP Option  11              - array of ip-address
  "host-name",                                - DHCP Option  12              - string
  "boot-size",                                - DHCP Option  13              - 16-bit unsigned integer
  "merit-dump",                               - DHCP Option  14              - text
  "domain-name",                              - DHCP Option  15              - text
  "swap-server",                              - DHCP Option  16              - ip-address
  "root-path",                                - DHCP Option  17              - text
  "extensions-path",                          - DHCP Option  18              - text
  "ip-forwarding",                            - DHCP Option  19              - boolean
  "non-local-source-routing",                 - DHCP Option  20              - boolean
  "policy-filter",                            - DHCP Option  21              - array of ip-address |
ip-address
  "max-dgram-reassembly",                     - DHCP Option  22              - 16-bit unsigned integer
  "default-ip-ttl",                           - DHCP Option  23              - 8-bit unsigned integer
  "path-mtu-aging-timeout",                   - DHCP Option  24              - 32-bit unsigned integer
  "path-mtu-plateau-table",                   - DHCP Option  25              - array of 16-bit
unsigned integer
  "interface-mtu",                            - DHCP Option  26              - 16-bit unsigned integer
  "all-subnets-local",                        - DHCP Option  27              - boolean
  "broadcast",                                - DHCP Option  28              - ip-address | offset
(for templates)
  "perform-mask-discovery",                   - DHCP Option  29              - boolean
  "mask-supplier",                            - DHCP Option  30              - boolean
  "router-discovery",                         - DHCP Option  31              - boolean
  "router-solicitation-address",              - DHCP Option  32              - ip-address
  "static-routes",                            - DHCP Option  33              - array of ip-address |
ip-address
  "trailer-encapsulation",                    - DHCP Option  34              - boolean
  "arp-cache-timeout",                        - DHCP Option  35              - 32-bit unsigned integer
  "ieee802-3-encapsulation",                  - DHCP Option  36              - boolean
  "default-tcp-ttl",                          - DHCP Option  37              - 8-bit unsigned integer
  "tcp-keepalive-interval",                   - DHCP Option  38              - 32-bit unsigned integer
  "tcp-keepalive-garbage",                    - DHCP Option  39              - boolean
  "nis-domain",                               - DHCP Option  40              - text
  "nis-servers",                              - DHCP Option  41              - array of ip-address
  "ntp-servers",                              - DHCP Option  42              - array of ip-address
  "vendor-encapsulated-options",              - DHCP Option  43              - string
  "netbios-name-servers",                     - DHCP Option  44              - array of ip-address
  "netbios-dd-server",                        - DHCP Option  45              - array of ip-address
  "netbios-node-type",                        - DHCP Option  46              - 8-bit unsigned
integer(1,2,4,8)
  "netbios-scope",                            - DHCP Option  47              - text
  "font-servers",                             - DHCP Option  48              - array of ip-address
  "x-display-manager",                        - DHCP Option  49              - array of ip-address
  "dhcp-requested-address",                   - DHCP Option  50              - ip-address
  "lease-time",                               - DHCP Option  51              - 32-bit unsigned integer
  "dhcp-option-overload",                     - DHCP Option  52              - 8-bit unsigned integer
  "dhcp-message-type",                        - DHCP Option  53              - 8-bit unsigned integer
  "dhcp-server-identifier",                   - DHCP Option  54              - ip-address
  "dhcp-parameter-request-list",              - DHCP Option  55              - array of 8-bit unsigned
integer
  "dhcp-message",                             - DHCP Option  56              - text
  "dhcp-max-message-size",                    - DHCP Option  57              - 16-bit unsigned integer
  "dhcp-renewal-time",                        - DHCP Option  58              - 32-bit unsigned integer
  "dhcp-rebinding-time",                      - DHCP Option  59              - 32-bit unsigned integer
  "vendor-class-identifier",                  - DHCP Option  60              - string
  "dhcp-client-identifier",                   - DHCP Option  61              - string
  "nwip-domain",                              - DHCP Option  62              - string
  "nwip-suboptions",                          - DHCP Option  63              - string
  "nisplus-domain",                           - DHCP Option  64              - text
  "nisplus-servers",                          - DHCP Option  65              - array of ip-address
  "tftp-server-name",                         - DHCP Option  66              - text
  "bootfile-name",                            - DHCP Option  67              - text
  "mobile-ip-home-agent",                     - DHCP Option  68              - array of ip-address
  "smtp-server",                              - DHCP Option  69              - array of ip-address
  "pop-server",                               - DHCP Option  70              - array of ip-address
  "nntp-server",                              - DHCP Option  71              - array of ip-address
  "www-server",                               - DHCP Option  72              - array of ip-address
  "finger-server",                            - DHCP Option  73              - array of ip-address
  "irc-server",                               - DHCP Option  74              - array of ip-address

    "option-244",                   - DHCP Option 244               - custom defined
    "option-245",                   - DHCP Option 245               - custom defined
    "option-246",                   - DHCP Option 246               - custom defined
    "option-247",                   - DHCP Option 247               - custom defined
    "option-248",                   - DHCP Option 248               - custom defined
    "option-249",                   - DHCP Option 249               - custom defined
    "option-250",                   - DHCP Option 250               - custom defined
    "option-251",                   - DHCP Option 251               - custom defined
    "option-252",                   - DHCP Option 252               - custom defined
    "option-253",                   - DHCP Option 253               - custom defined
    "option-254",                   - DHCP Option 254               - custom defined
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $option->name();
#Modify name
$option->name("host-name");
```

num( )

Use this method to set or retrieve the numeric value of the DHCP option.

Note that specifying "num" without "name" is supported only for predefined options and custom options with names that haven't been modified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the number of the DHCP option. It must be an integer ranging from 1 to 254.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get num
my $num = $option->num();
#Modify num
$option->num("12");
```

value( )

Use this method to set or retrieve the custom value of the DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the data type of the DHCP option. Valid values are

```
  "boolean"                          - Specify "true" or "false" for boolean values.

  "ip-address"                       - Specify an IPv4 address. An IPv4 address is a 32-bit number
in dotted decimal notation.
                                       It consists of four 8-bit groups of decimal digits separated
                                       by decimal points (example: "192.168.1.2").

  "array of ip-address"              - Specify a list of IPv4 addresses, each separated by a comma.
                                       (example: "192.168.1.2, 10.11.12.13, 79.2.3.1")

  "string"                           - Specify a value in ASCII text string or
                                       a list of hexadecimal characters (0-9, a-f, or A-F) without
spaces and separated by colons.

  "text"                             - Specify a value in ASCII text string.

  "8-bit unsigned integer"           - Specify a numeric value between 0 and 255.

  "array of 8-bit unsigned integer"  - Specify a list of 8-bit unsigned integers, each separated by
a comma.

  "16-bit unsigned integer"          - Specify a numeric value between 0 and 65535.

  "array of 16-bit unsigned integer" - Specify a list of 16-bit unsigned integers, each separated by
a comma.

  "32-bit unsigned integer"          - Specify a numeric value between 0 and 4294967295.

  "array of 32-bit unsigned integer" - Specify a list of 32-bit unsigned integers, each separated by
a comma.

  "8-bit signed integer"             - Specify a numeric value between -128 and 127.

  "array of 8-bit signed integer"    - Specify a list of 8-bit signed integers, each separated by a
comma.

  "16-bit signed integer"            - Specify a numeric value between -32768 and 32767.

  "array of 16-bit signed integer"   - Specify a list of 16-bit signed integers, each separated by a
comma.

  "32-bit signed integer"            - Specify a numeric value between -2147483648 and 2147483647.

  "array of 32-bit signed integer"   - Specify a list of 32-bit signed integers, each separated by a
comma.

  "domain-list"                      - Specify a list of domain names, each double-quoted and
separated by a comma.
                                       (example: '"domain1.com","domain2.com","domain3.com"')
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get value
my $value = $option->value();
#Modify value
$option->value("abc.com");
```

vendor_class( )

Use this method to set an option space name as the vendor class value of a DHCP option or to retrieve an option space name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the defined option space name in string format. The default option space name is "DHCP".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get vendor_class
my $name = $option->vendor_class();
#Modify vendor_class
$option->vendor_class("DHCP");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP Option object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP Option object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP Option object

```
my $dhcp_option = Infoblox::DHCP::Option->new(
    name         => "subnet-mask",
    num          => "1",
    value        => "255.0.0.0",
    vendor_class => "DHCP"
);
unless($dhcp_option) {
       die("Construct DHCP option object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP option object created successfully\n";
```

#Get the Grid DHCP object and add a DHCP option to it

```
#Get the Grid DHCP object
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::DHCP",
```

```
    grid   => "Infoblox"
);
my $object = $retrieved_objs[0];
unless ($object) {
       die("Get Grid DHCP object failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get Grid DHCP object found at least 1 matching entry\n";

#Apply the changes to the Grid DHCP object
$object->options([$dhcp_option]);

#Apply the changes
$session->modify($object)
    or die("Modify Grid DHCP object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "Grid DHCP object with DHCP option updated to Infoblox appliance successfully\n";
```

#Modify DHCP option

```
#Modify an existing option object

#Modifying the name of the DHCP option object.
$dhcp_option->name("host-name");

#Modifying the value of the DHCP option object.
$dhcp_option->value("infoblox.com");

#Modifying the number of the DHCP option object.
$dhcp_option->num("12");

#Apply changes to the Grid DHCP object.
$object->options([$dhcp_option]);

#Update Grid DHCP object through the Infoblox session.
$session->modify($object)
            or die("modify Grid DHCP object failed: ",
                $session->status_code() . ":" . $session->status_detail());
       print "Grid DHCP object with modified DHCP option updated to Infoblox appliance successfully\n";
```

#Remove DHCP option

```
#Apply changes to the Grid DHCP object.
$object->options([]);

#Update Grid DHCP object through the Infoblox session.
$session->modify($object)
            or die("modify Grid DHCP object failed: ",
                $session->status_code() . ":" . $session->status_detail());
       print "Removed DHCP option from Grid DHCP object successfully\n";

####PROGRAM ENDS####
```

NAME

Infoblox::DHCP::Option60MatchRule - DHCP Option60MatchRule object.

DESCRIPTION

An Option60MatchRule object allows specifying match rules for Option 60 globally.

CONSTRUCTOR

```
my $option60_match_rule = Infoblox::DHCP::Option60MatchRule->new(
                            match_value      => $string,          #Required
                            option_space     => $string,          #Required
                            is_substring     => "true" | "false", #Optional / Default is undefined
                            substring_offset => $num,             #Optional / Default is undefined
                            substring_length => $num              #Optional / Default is undefined
                          );
```

MODULE METHODS

The following functions are available to be applied to a DHCP Option60MatchRule object.

Infoblox::Grid::DHCP->option60_match_rules( )

Use this function to specify match rule for option60 at grid level. See Infoblox::Grid::DHCP->option60_match_rules() for parameters and return values.

Example

```
#Construct a DHCP Option60MatchRule object
my $option60_match_rule = Infoblox::DHCP::Option60MatchRule->new(
                                        "option_space" => "infospace",
                                        "match_value" => "Nortel-i2004-A",
                                        "is_substring" => "true",
                                        "substring_offset" => "8",
                                        "substring_length" => "14"
                                      );

# Configure DHCP Option60MatchRule on the Grid DHCP object
my $response = $grid_dhcp->option60_match_rules([$option60_match_rule]);
```

Infoblox::Grid::Member::DHCP->option60_match_rules( )

Use this function to specify match rule for option60 at member level. See Infoblox::Grid::Member::DHCP->option60_match_rules() for parameters and return values.

Example

```
#Construct a DHCP Option60MatchRule object
my $option60_match_rule = Infoblox::DHCP::Option60MatchRule->new(
                                        "option_space" => "infospace",
```

```
                                        "match_value" => "Nortel-i2004-A",
                                        "is_substring" => "true",
                                        "substring_offset" => "10",
                                        "substring_length" => "24"
                                      );

    # Configure DHCP Option60MatchRule on the Grid Member DHCP object
    my $response = $grid_member_dhcp->option60_match_rules([$option60_match_rule]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP Option60MatchRule object.

match_value( )

Use this method to set or retrieve the match value of a DHCP Option60MatchRule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired match value in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    # Get match_value
    my $match_value = $option60_match_rule->match_value();
    # Modify match_value
    $option60_match_rule->match_value("SUNW");
```

option_space( )

Use this method to set or retrieve the option space of a DHCP Option60MatchRule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an string that contains defined Infoblox::DHCP::OptionSpace object. See Infoblox::DHCP::OptionSpace for parameters and return values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    # Get option_space
    my $match_value = $option60_match_rule->option_space();
    # Modify option_space
    $option60_match_rule->option_space("new_option");
```

is_substring( )

Use this method to set or retrieve the is_substring flag of a DHCP Option60MatchRule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the is_substring flag or "false" to deactivate/unset it. The default value for this field is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get is_substring
my $is_substring = $option60_match_rule->is_substring();
# Modify is_substring
$option60_match_rule->is_substring("true");
```

substring_offset( )

Use this method to set or retrieve the substring_offset of a DHCP Option60MatchRule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The substring_offset for the DHCP Option60MatchRule object (range from 0 to 65535). The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get substring_offset
my $substring_offset = $option60_match_rule->substring_offset();
# Modify substring_offset
$option60_match_rule->substring_offset("10");
```

substring_length( )

Use this method to set or retrieve the substring_length of a DHCP Option60MatchRule object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The substring_length for the DHCP Option60MatchRule object (range from 0 to 65535). The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get substring_length
my $substring_length = $option60_match_rule->substring_length();
# Modify substring_length
$option60_match_rule->substring_length("23");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP Option60MatchRule insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $option space1   Infoblox::DHCP::OptionSpace  new
```

```
                    =                                   ->   (
                                                        "name" => "infospace"
                                                        );
my $response = $session->add( $option_space1);
print "Add option space operation success \n" if ($response );
print "Add option space operation failed  \n" if ( not $response );

#Create a DHCP OptionDefinition object.>
my $option60_match_rule = Infoblox::DHCP::Option60MatchRule->new(
                                                        "option_space" => "infospace",
                                                        "match_value" => "Nortel-i2004-A",
                                                        "is_substring" => "true",
                                                        "substring_offset" => "0",
                                                        "substring_length" => "14"
                                                        );
unless ($option60_match_rule) {
     die("Construct DHCP Option60MatchRule failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}

#Get on Grid DHCP object to add Option60MatchRule object>
my @result = $session->get(
    object => "Infoblox::Grid::DHCP",
    grid   => "Infoblox"
    )
    or die("get DHCP failed: ",
                $session->status_code(). ":" .$session->status_detail());
print "get grid DHCP Objcet successful.\n";

unless (scalar(@result) == 0) {
my $griddhcp = $result[0];
if ($griddhcp) {

 $griddhcp->option60_match_rules([$option60_match_rule]);

  #Applying the changes to appliance through session.
  $session->modify($griddhcp)
      or die("Modify DHCP failed: ",
         $session->status_code(). ":" .$session->status_detail());
  print"Modified Grid DHCP Object successfully.\n";
    }
    } else {
      print "No Grid DHCP object found.";
   }

#To remove Option60MatchRule object in Grid DHCP object>
my @result = $session->get(
    object => "Infoblox::Grid::DHCP",
    grid   => "Infoblox"
    )
    or die("get DHCP failed: ",
                $session->status_code(). ":" .$session->status_detail());
print "get grid DHCP Objcet successful.\n";

unless (scalar(@result) == 0) {
my $griddhcp = $result[0];
if ($griddhcp) {

$griddhcp->option60_match_rules(undef);

  #Applying the changes to appliance through session.
  $session->modify($griddhcp)
      or die("Modify DHCP failed: ",
         $session->status_code(). ":" .$session->status_detail());
  print"Modified Grid DHCP Object successfully to remove Option60MatchRule object.\n";
  }
    } else {
      print "No Grid DHCP object found.";
   }

#Get OptionSpace object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::OptionSpace",
    name   => "infospace"
);
my $object = $retrieved_objs[0];
unless  $object
```

```
        (       ) {
    die("Get OptionSpace object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get OptionSpace object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove OptionSpace object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "OptionSpace object removed successfully \n";

####PROGRAM ENDS####

DESCRIPTION

An OptionDefinition defines a DHCP option within a specific option space. A custom option can be defined in the predefined DHCP option space or in the user-defined vendor option space. To define an option, add the option definition to the required option space.

CONSTRUCTOR

```
my $option_definition1 = Infoblox::DHCP::OptionDefinition->new(
                                name  => $string, #Required
                                code  => $num,    #Required
                                space => $string, #Optional / Default is DHCP
                                type  => $string, #Optional / Default is string
                               );
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that can be applied to a DHCP option definition object.

Infoblox::Session->add( )

Use this method to add a option definition object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Create a DHCP OptionDefinition object.
my $option_definition1 = Infoblox::DHCP::OptionDefinition->new(
                                    space => "SUNW",
                                    name  => "JumpStart-server",
                                    code  => "6",
                                    type  => "text"
                                    );
# Submit for adding
my $response = $session->add( $option_definition1 );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching DHCP option definition objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP option definition object:

 name - A name for the option definition in string format (regular expression).
```

```
  code - Option number. Either a name or code is required.
  space- Optional. The option space in which the option is defined. The default is the DHCP option
space.
```

Example

```
#Getting option by name
my  @result_array = $session->get(
                        object   => "Infoblox::DHCP::OptionDefinition",
                        space    => "SUNW",
                        name     => "JumpStart-server",
                        );

#Getting option by code
my @result_array = $session->get(
                        object   => "Infoblox::DHCP::OptionDefinition",
                        space    => "DHCP",
                        code     => 176,
                        );
```

Infoblox::Session->modify( )

Use this method to modify a DHCP option definition object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify code
$object->code(20);
# Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->search( )

Use this method to retrieve all the matching DHCP option definition objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP option definition object:

  name - A name for the option definition in string format (regular expression).
  code - Option number. Either a name or code is required.
  space- Optional. The option space in which the option is defined. The default is the DHCP option
space.
```

Example

```
#Getting option by name
my  @result_array = $session->search(
                        object   => "Infoblox::DHCP::OptionDefinition",
                        space    => "SUNW",
                        name     => "JumpStart-server",
                        );

#Getting option by code
my @result_array = $session->search(
                        object   => "Infoblox::DHCP::OptionDefinition",
                        space    => "DHCP",
                        code     => 176,
                        );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP option definition object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` to retrieve the specific object, and then submit this object for removal.

Example

```
my  @result_array = $session->get(
                        object   => "Infoblox::DHCP::OptionDefinition",
                        space    => "SUNW",
                        name     => "JumpStart-server",
                        );

# find the desired object from retrieved list.
```

```
my $desired_obj = $result_array[0];

# Submit for removal
my $response = $session->remove($desired_obj);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP option definition object.

name( )

Use this method to set or retrieve the name of a DHCP option definition object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get name
my $option_definitionname = $option_definition1 ->name();
# Modify name
$option_definition1 ->name("Start-server");
```

code( )

Use this method to set or retrieve the code of a DHCP option definition object. An option code number is used to identify the DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Number for the option code. Value must be between 1 and 254. Values 1-79, 81-82, 85-87, 89, 91-92, 98, 112-114, 118-119, 124-125 are predefined. These option codes have corresponding predefined Types. Therefore, you cannot change the predefined Types.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get code
my $option_definitionname = $option_definition1 ->code();
# Modify code
$option_definition1 ->code(14);
```

space( )

Use this method to set or retrieve the space of a DHCP option definition object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the space name in string format.

Returns

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get space
my $option_space = $option_definition1 ->space();
# Modify space
$option_definition1 ->space("SUNW");
```

---

type( )

Use this method to set or retrieve the data type of the grid DHCP option.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The accepted types are the following:

```
  "boolean"                 - For "true" or "false" boolean values.

  "ip-address"              - For a single IPv4 address. An IPv4 address is a 32-bit number in dotted
decimal notation.
                              It consists of four 8-bit groups of decimal digits separated
                              by decimal points (example: "192.168.1.2").

  "array of ip-address"     - For a list of IPv4 addresses, each separated by a comma.
                              (example: "192.168.1.2, 10.11.12.13, 79.2.3.1")

  "string"                  - For value in ASCII text string or
                              a list of hexadecimal characters (0-9, a-f, or A-F) without spaces and
separated by colons.

  "text"                    - For value in ASCII text string.

  "domain-name"             - For domain name in ASCII text format

  "domain-list"             - For a list of domain names, each separated by a comma.

  "8-bit unsigned integer"  - For numeric value between 0 and 255.

  "16-bit unsigned integer" - For numeric value between 0 and 65535.

  "32-bit unsigned integer" - For numeric value between 0 and 4294967295.

  "8-bit signed integer"    - For numeric value between -128 and 127.

  "16-bit signed integer"   - For numeric value between -32768 and 32767.

  "32-bit signed integer"   - For numeric value between -2147483648 and 2147483647.

  "array of 8-bit unsigned integer"  - For a list of numeric values between 0 and 255, each separated
by a comma.

  "array of 16-bit unsigned integer" - For a list of numeric values between 0 and 65535, each
separated by a comma.

  "array of 32-bit unsigned integer" - For a list of numeric values between 0 and 4294967295, each
separated by a comma.

  "array of 8-bit integer"           - For a list of numeric values between -128 and 127, each
separated by a comma.

  "array of 16-bit integer"          - For a list of numeric values between -32768 and 32767, each
separated by a comma.

  "array of 32-bit integer"          - For a list of numeric values between -2147483648 and
2147483647, each separated by a comma.
```

The following types are valid only for `Microsoft(r)` server options

```
  "binary"

  "encapsulated"

  "array of string"

  "array of 64-bit unsigned integer" - For a list of numeric values between 0 and 1.8446744 * 10^19

  "64-bit unsigned integer"          - For a list of numeric values between 0 and 1.8446744 * 10^19,
each separated by a comma.
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get type
my $option_definitiontype = $option_definition1 ->type();
# Modify type
$option_definition1 ->type("string");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP Network insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $option_space1 = Infoblox::DHCP::OptionSpace->new(
                                                "name" => "SUNW"
                                                );
my $response = $session->add( $option_space1);
print "Add option space operation success \n" if ($response );
print "Add option space operation failed  \n" if ( not $response );
```

#Create a DHCP OptionDefinition object.

```
my $option_definition1 = Infoblox::DHCP::OptionDefinition->new(
                                space => "SUNW",
                                name  => "JumpStart-server",
                                code  => "6",
                                type  => "text"
                              );
        unless ($option_definition1) {
        die("Construct DHCP OptionDefinition failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
  }
 print "DHCP OptionDefinition object created successfully\n";

 #Add the DHCP OptionDefinition object to Infoblox appliance through a session
       my $response = $session->add( $option_definition1 )
       or die("Add a DHCP  OptionDefinition object failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Add a DHCP  OptionDefinition object successfully\n";
```

#Get and modify a DHCP OptionDefinition object attribute

```
#Get Network through the session
my  @retrieved_objs = $session->get(
              object   => "Infoblox::DHCP::OptionDefinition",
              space  => "SUNW",
              name   => "JumpStart-server",
            );

my $object = $retrieved_objs[0];

unless ($object) {
    die("Get DHCP OptionDefinition object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get DHCP OptionDefinition object found at least 1 matching entry\n";

#Modify one of the attributes of the specified Network attribute

 $object->code(20);    #Apply the changes

$session->modify($object)
    or die("Modify DHCP OptionDefinition attribute failed: ",
           $session->status_code() . ":" . $session->status_detail());
```

```
print "DHCP OptionDefinition object modified successfully \n";
```

#Remove a DHCP OptionDefinition Object

```
 #Get DHCP OptionDefinition object through the session
 my  @retrieved_objs = $session->get(
                  object =>"Infoblox::DHCP::OptionDefinition",
                  space  => "SUNW",
                  name   => "JumpStart-server",
            );

   my $object = $retrieved_objs[0];

   unless ($object) {
    die("Get DHCP OptionDefinition object failed: ",
        $session->status_code() . ":" . $session->status_detail());
    }

print "Get DHCP OptionDefinition object found at least 1 matching entry\n";
```

#Submit the object for removal

```
$session->remove($object)
    or die("Remove Network failed: ",
        $session->status_code() . ":" . $session->status_detail());

print "DHCP OptionDefinition removed successfully \n";

#Remove option space.

my $response = $session->remove( object => "Infoblox::DHCP::OptionSpace" ,
                                 name   => "SUNW",
                               );
print "Remove option space success \n" if ($response );
print "Remove option space failed  \n" if ( not $response );

NAME

Infoblox::DHCP::OptionSpace - DHCP OptionSpace object.

DESCRIPTION

An Option Space defines a namespace in which vendor options can be defined. To define a specific vendor option space, add an option space to DHCP.

CONSTRUCTOR

```
my $option_space = Infoblox::DHCP::OptionSpace->new(
      name             => $string,                          #Required
      comment          => $string,                          #Optional, default is undefined
);
```

SESSION METHODS

This section describes all the methods in Infoblox::Session module that can be applied to a DHCP OptionSpace object.

Infoblox::Session->add( )

Use this method to add a DHCP OptionSpace object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct a DHCP OptionSpace object
my $option_space = Infoblox::DHCP::OptionSpace->new(
      name => "infospace",
      comment => "some comment"
);
#Submit for addition
my $response = $session->add($option_space)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP OptionSpace object:

 name     - Required. Option space name in string format.
 comment  - Optional. Option space comment.
```

Example

```
#Get DHCP OptionSpace object through the session
```

```
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::OptionSpace",
    name   => "infospace",
);
```

Infoblox::Session->modify( )

Use this method to modify a DHCP OptionSpace object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the name.
$option_space->name("info_space");
#Submit modification
my $response = $session->modify( $option_space );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP OptionSpace object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` to retrieve the specific DHCP OptionSpace object, and then submit this object for removal.

Example

```
#Get DHCP OptionSpace object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::OptionSpace",
    name   => "info_space",
);
#Find the desired object from the retrieved list.
my $desired_option_space = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_option_space );
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP OptionSpace object:

 name     - Optional. Option space name in string format (regular expression).
 comment  - Optional. Option space comment (regular expression).
```

Example

```
#Get DHCP OptionSpace object through the session
my @retrieved_objs = $session->search(
    object => "Infoblox::DHCP::OptionSpace",
    comment => ".*comm.*"
);
```

METHODS

This section describes all the methods that can used to set and retrieve the attribute values of a DHCP OptionSpace object.

name( )

Use this method to set or retrieve name of option space object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name in string format with a maximum of 256 bytes.

Returns

If parameter is specified, the method returns true when the modification succeeds, and returns false when the operation fails.

If parameter is not specified, the method returns the attribute value.

Example

```
#Get name
my $name = $option_space->name();
#Modify name
$option_space->name("info_space");
```

comment( )

Use this method to set or retrieve a comment about the option space object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If the parameter is specified, the method returns true when the modification succeeds, and returns false when the operation fails.

If the parameter is not specified, the method returns the attribute value.

Example

```
#Get comment
my $comment = $option_space->comment();
#Modify comment
$option_space->comment("my comment");
```

space_type

Use this method to retrieve the type of this option space.

Parameter

None.

Returns

The method returns the attribute value, which can be either 'predefined_dhcp' or 'vendor_space'.

Example

```
#Get space_type
my $space_type = $option_space->space_type();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an OptionSpace object, such as get, add, modify and remove. In addition, the sample includes error handling for the operations.

#Preparation prior to a DHCP OptionSpace object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create an OptionSpace object

```
my $option_space = Infoblox::DHCP::OptionSpace->new (
       "name" => "infospace"
);
```

```
unless($option_space) {
     die("Construct option_space filter failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "OptionSpace object created successfully\n";

#Verify if the DHCP OptionSpace exists in the Infoblox appliance
my $object = $session->get(
       object => "Infoblox::DHCP::OptionSpace",
       name   => "infospace"
);
unless ($object) {
   print "option space does not exist on server, safe to add the option_space\n";
   $session->add($option_space)
      or die("Add option space failed: ",
             $session->status_code() . ":" . $session->status_detail());
}
print "DHCP OptionSpace added successfully\n";
```

#Get and Modify an OptionSpace object

```
#Get OptionSpace object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::OptionSpace",
    name   => "infospace"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get OptionSpace object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get OptionSpace object found at least 1 matching entry\n";

#Modify name of the obtained OptionSpace object
$object->name("info_space");

#Apply the changes
$session->modify($object)
    or die("Modify OptionSpace object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "OptionSpace object modified successfully \n";
```

#Remove an OptionSpace object

```
#Get OptionSpace object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::OptionSpace",
    name   => "info_space"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get OptionSpace object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get OptionSpace object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove OptionSpace object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "OptionSpace object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::OrderedRanges - Ordered Ranges object.

DESCRIPTION

An object type to set or retrieve an ordered list of DHCP ranges in a network.

CONSTRUCTOR

```
my $ordered_ranges = Infoblox::DHCP::OrderedRanges->new(
                     network                  => $network,                    #Required
                     ranges                   => [$range1, $range2, ...],     #Required
);
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to an Ordered Ranges object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

No object is added in this method, but the ranges for the specified network assume the specified order.

Example

```
#Construct an object
my $ordered_ranges = Infoblox::DHCP::OrderedRanges->new(

network => $network,
                                                        ranges  => [$range1, $range2]
                                                       );
#Submit for addition
my $response = $session->add( $ordered_ranges );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific Ordered Ranges object:

network - Required. An Infoblox::DHCP::Network object.
```

Examples

```
my @retrieved_objs = $session->get(
    object   => "Infoblox::DHCP::OrderedRanges",
    network  => $network
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

No object is modified in this method, but the ranges for the specified network assume the specified order.

Example

```
#Use this method to modify the comment.
$ordered_ranges->ranges([$range4, $range2, $range3, $range1]);
#Submit modification
my $response = $session->modify( $ordered_ranges );
```

METHODS

Use the following methods to access the attributes of an Infoblox::DHCP::OrderedRanges object. Specify a parameter to set the attribute's value, or omit the parameter to get the attribute's value.

network( )

Use this method to set or retrieve the parent network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An Infoblox::DHCP::Network object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting network
my $network = $ordered_ranges->network();
#Modifying network
$ordered_ranges->network($nw1);
```

ranges( )

Use this method to set or retrieve an ordered list of DHCP ranges object references.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A list of Infoblox::DHCP::Range objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting ranges
my $ranges_ref = $ordered_ranges->ranges();
#Modifying ranges
$ordered_ranges->ranges([$range1, $range2, @range3]);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to the range reordering

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
```

```
my $host_ip =  "192.168.1.2";
my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
    );
unless($session){
        die("Constructor for session failed: ",
              Infoblox::status_code(). ":" . Infoblox::status_detail());
}
print "Session created successfully.\n";

my $network = Infoblox::DHCP::Network->new(
                                          network   => "10.0.0.0/255.255.0.0",
                                          comment   => "add network",
                                         );

$session->add($network)
    or die("Add network failed: ",
              $session->status_code(). ":" .$session->status_detail());

print"Network added successfully.\n";

my $range = Infoblox::DHCP::Range->new(
                                       start_addr              => "10.0.0.1",
                                       end_addr                => "10.0.0.10",
                                       network                 => "10.0.0.0/16",
                                       comment                 => "range 1",
                                      );

$session->add($range)
    or die("Add range failed: ",
              $session->status_code(). ":" .$session->status_detail());

print"Range added successfully.\n";

$range = Infoblox::DHCP::Range->new(
                                     start_addr              => "10.0.0.21",
                                     end_addr                => "10.0.0.30",
                                     network                 => "10.0.0.0/16",
                                     comment                 => "range 2",
                                   );

$session->add($range)
    or die("Add range failed: ",
              $session->status_code(). ":" .$session->status_detail());

print"Range added successfully.\n";

$range = Infoblox::DHCP::Range->new(
                                     start_addr              => "10.0.0.31",
                                     end_addr                => "10.0.0.40",
                                     network                 => "10.0.0.0/16",
                                     comment                 => "range 3",
                                   );

$session->add($range)
    or die("Add range failed: ",
              $session->status_code(). ":" .$session->status_detail());

print"Range added successfully.\n";
```

#Get the current range order.

```
my $tnetwork = Infoblox::DHCP::Network->new(
                                           network   => "10.0.0.0/255.255.0.0",
                                          );
my $or = $session->get(
     object  => "Infoblox::DHCP::OrderedRanges",
     network => $tnetwork
);

unless($or){
       die("Get ordered ranges failed: ",
                $session->status_code() . ":" . $session->status_detail());
```

```
        }

print "Get ordered ranges object found at least 1 matching entry\n";

my ($r1, $r2, $r3) = @{$or->ranges()};

print "The current order of the ranges is : " . $r1->comment() . "," .
                $r2->comment() . "," . $r3->comment() . "\n";
```

#Modify the range order.

```
$or->ranges([$r3, $r2, $r1]);

#Apply the change
$session->modify($or)
      or die("Modify ordered ranges failed: ",
                $session->status_code(). ":" .$session->status_detail());

print "Ordered ranges modified successfully.\n";

$or = $session->get(
    object  => "Infoblox::DHCP::OrderedRanges",
    network => $tnetwork
);

unless($or){
      die("Get ordered ranges failed: ",
                $session->status_code() . ":" . $session->status_detail());
      }

print "Get ordered ranges object found at least 1 matching entry\n";

($r1, $r2, $r3) = @{$or->ranges()};

print "The current order of the ranges is : " . $r1->comment() . "," .
                $r2->comment() . "," . $r3->comment() . "\n";

NAME

Infoblox::DHCP::Range - DHCP Range object.

DESCRIPTION

A DHCP range defines the specified range of IP addresses in a network. A DHCP range should be added for a network so the Infoblox appliance can assign IP addresses within that specified range to DHCP clients. If the client is on a network that is assigned a DHCP range, the device distributes an available IP address from that range to the DHCP client, or to a DHCP relay agent if the request came through an agent. The DHCP range should also be assigned with a device. If devices are in a grid, the particular member serving DHCP for the DHCP range must be specified. If the server is an independent device, this device must be specified as the member that serves the DHCP range.

CONSTRUCTOR

```
 my $dhcp_range = Infoblox::DHCP::Range->new(

     end_addr                        => $ipv4addr,                                  #Required
     network                         => $network,                                   #Optional
     network_view                    => $NetworkView,                               #Optional / Default is
system-defined default network view
     start_addr                      => $ipv4addr,                                  #Required
     always_update_dns               => "true" | "false",                           #Optional / Default is
"false"

     unknown_clients_option          => "Allow" | "Deny",                         #Optional / Default is
undefined
     update_dns_on_lease_renewal     => "true" | "false",                         #Optional / Default
value is "false"
     discovery_blackout_setting      => $blackout,                                #Optional
     port_control_blackout_setting   => $blackout,                                #Optional
     override_blackout_setting       => "true" | "false",                         #Optional / Default
value is "false"
     same_port_control_discovery_blackout => "true" | "false",                    #Optional / Default
value is "false"
     subscribe_settings          => $subscribe_settings,                          #Optional / Default is
undefined
     override_subscribe_settings => 'true' | 'false',                             #Optional / Default is
'false'
      );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that you can apply to a DHCP range object.

Infoblox::Session->add( )

Use this method to add a DHCP range object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $dhcp_range = Infoblox::DHCP::Range->new(
        end_addr                => "10.0.0.10",
        network                 => "10.0.0.0/8",
        start_addr              => "10.0.0.1",
        bootfile                => "bootfile1.com",
        bootserver              => "someserver.com",
        comment                 => "add range",
        ddns_generate_hostname  => "true",
        deny_all_clients        => "true",
        deny_bootp              => "true",
        disable                 => "true",
        enable_ddns             => "true",
        exclude                 => [$exclusion_range],
        filters                 => [$filter],
        member                  => $memberdhcp,
        network                 => $nview,
        nextserver              => "3.3.3.3",
        options                 => [$option1],
        pxe_lease_time          => "3600",
        recycle_leases          => "true",
);

# Submit for addition
my $response = $session->add( $dhcp_range );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
Apply the following attributes to get a specific DHCP range object:

start_addr             - Optional. Starting IP address of DHCP range within the network.
network_view           - Optional. Network view in which the DHCP range is located. By default, all
network views are searched.
extattrs               - Optional. A hash reference containing extensible attributes.
extensible_attributes  - Optional. A hash reference containing extensible attributes.
failover_assoc         - Optional. The name of the associated failover peer.
member                 - Optional. The member or Microsoft server serving the range. The valid value
is an Infoblox::DHCP::Member, Infoblox::DHCP::MSServer, Infoblox::Grid::Member::DHCP or
Infoblox::Grid::MSServer::DHCP object.
server_association_type - Optional. The server association type for the range.
```

Examples

```
my @retrieved_objs = $session->get(
                     object     => "Infoblox::DHCP::Range",
                     start_addr => "10.0.0.1" );

my @retrieved_objs = $session->get(
                     object       => "Infoblox::DHCP::Range",
                     start_addr   => "10.0.0.1",
                     network_view => "default" );

my @retrieved_objs = $session->get(
                     object               => "Infoblox::DHCP::Range",
                     extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify a DHCP range object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use method to modify the comment.
$dhcp_range->comment("this is a modified comment");
# Submit modification
my $response = $session->modify( $dhcp_range );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP range object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP range object, and then submit this object for removal.

Example

```
# Get the objects with the same name
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::Range",
    start_addr   => "10.0.0.1",
    newtork_view => "default" );
# Find the desired object from the retrieved list.
my $desired_dhcp_range = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_dhcp_range );
```

Infoblox::Session->search( )

Use this method to search for DHCP range objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Key References

```
 Apply the following attributes to search for a DHCP range object:

  network      - Optional. Network in CIDR format (regular expression).
  network_view - Optional. Network view in which the DHCP range is located. By default, all network
views are searched.
  start_addr   - Optional. IPv4 address in dotted decimal notation (regular expression).
  end_addr     - Optional. IPv4 address in dotted decimal notation (regular expression).
  comment      - Optional. Comment in string format (regular expression).
  extattrs     - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  failover_assoc        - Optional. The name of the associated failover peer.
  member                - Optional. The member or Microsoft server serving the range. The valid value
is an Infoblox::DHCP::Member, Infoblox::DHCP::MSServer, Infoblox::Grid::Member::DHCP or
Infoblox::Grid::MSServer::DHCP object.
  server_association_type - Optional. The server association type for the range.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
# search for DHCP range object with start address having last octet as 1
my @retrieved_objs = $session->search(
    object       => "Infoblox::DHCP::Range",
    network      => "10.0.0.0/.",
    network_view => "default",
    start_addr   => ".*1",
    comment      => ".*comment" );

# search for DHCP range objects defining "Santa Clara" for "Site" extensible attribute
my @retrieved_objs = $session->search(
    object               => "Infoblox::DHCP::Range",
    extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a DHCP range.

always_update_dns( )

Use this method to set or retrieve the always_update_dns flag of a DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This flag only applies if the range is associated with a Microsoft (r) server. If it is set to "true", the DHCP server will always update DNS, regardless of the requests from the DHCP clients. If this flag is set to false, clients will be allowed to update DNS when they request it.

Parameter

Specify "true" to set the always_update_dns flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get always_update_dns
my $always_update_dns = $dhcp_range->always_update_dns();
#Modify always_update_dns
$dhcp_range->always_update_dns("false");
```

bootfile( )

Use this method to set or retrieve a bootfile name which is the name of the file the client must download.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::Range->bootserver() and Infoblox::DHCP::Range->nextserver().

Parameter

The boot file name in string format with a maximum of 128 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootfile
my $bootfile = $dhcp_range->bootfile();
#Modify bootfile
$dhcp_range->bootfile("bootfile2.com");
#Un-override bootfile
$dhcp_range->bootfile(undef);
```

bootserver( )

Use this method to set or retrieve a bootserver name which is the name of the server where the boot file is stored.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::Range->bootfile() and Infoblox::DHCP::Range->nextserver().

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootserver
my $bootserver = $dhcp_range->bootserver();
#Modify bootserver
$dhcp_range->bootserver("anotherserver.com");
#Un-override bootserver
$dhcp_range->bootserver(undef);
```

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $dhcp_range->comment();
#Modify comment
$dhcp_range->comment("Modifying the DHCP range comment");
```

cloud_info( )

Use this method to set or retrieve cloud API related information for the Infoblox::DHCP::Range object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a Infoblox::Grid::CloudAPI::Info object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $dhcp_range->cloud_info();
# Modify cloud_info
$dhcp_range->cloud_info($cloud_info_object);
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP Range object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_dddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $dhcp_range->ddns_domainname();
#Modify ddns_domainname
$dhcp_range->ddns_domainname("test_domain.com");
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a DHCP range.

Enable this method to allow only the DHCP server to generate a hostname.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ddns_generate_hostname flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_generate_hostname
my $ddns_generate_hostname = $dhcp_range->ddns_generate_hostname();
#Modify ddns_generate_hostname
$dhcp_range->ddns_generate_hostname("false");
```

deny_all_clients( )

Use this method to set or retrieve the deny_all_clients flag of a DHCP range.

Enable this method to deny all lease requests for the DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_all_clients flag or "false" to deactivate/unset it. The default value for this field is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_all_clients
my $deny_all_clients = $dhcp_range->deny_all_clients();
#Modify deny_all_clients
$dhcp_range->deny_all_clients("false");
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP range.

Enable this method to deny all BOOTP requests.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is false which indicates that this attribute inherit the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $dhcp_range->deny_bootp();
#Modify deny_bootp
$dhcp_range->deny_bootp("false");
```

disable( )

Use this method to set or retrieve the disable flag of a DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value for this field is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $dhcp_range->disable();
#Modify disable
$dhcp_range->disable("false");
```

discovery_basic_poll_setting( )

Use this method to set or retrieve the discovery_basic_poll_setting value of a DHCP Range.

Include the specified parameter to set the attribute value.

Parameter

The valid value is object of the Infoblox::Grid::Discovery::BasicPollSettings manpage.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_basic_poll_setting
my $discovery_basic_poll_setting = $dhcp_range->discovery_basic_poll_setting();
#Modify discovery_basic_poll_setting
$dhcp_range->discovery_basic_poll_setting($poll_setting);
```

discovery_member( )

Use this method to set or retrieve the discovery_member value of a DHCP Range.

Parameter

The discovery member name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_member
my $discovery_member = $dhcp_range->discovery_member();
#Modify discovery_member
$dhcp_range->discovery_member("test.localdomain");
```

discover_now_status( )

Use this method to retrieve the current discovery status. This attribute is read-only.

'discover_now_status' will not be returned by default, use 'return_methods' to request it if needed.

Parameter

None.

Returns

The method returns the attribute value that can be 'COMPLETE', 'FAILED', 'NONE', 'PENDING' or 'RUNNING'.

Example

```
#Get discover_now_status
my $discover_now_status = $dhcp_range->discover_now_status();
```

discovery_blackout_setting( )

Use this method to set or retrieve the discovery blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If port_control_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when discovery_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->discovery_blackout_setting($blackout); $network->override_blackout_setting("false");

will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->discovery_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get discovery_blackout_setting
my $discovery_blackout_setting = $dhcp_range->discovery_blackout_setting();
#Modify discovery_blackout_setting
$dhcp_range->discovery_blackout_setting($blackout);
```

enable_discovery( )

Use this method to set or retrieve the enable_discovery value of a DHCP Range. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_enable_discovery method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_enable_discovery attribute to "false".

Enable this flag if you want to set discovery for this object.

Parameter

Specify "true" to set the enable_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_discovery
my $enable_discovery = $dhcp_range->enable_discovery();
#Modify enable_discovery
$dhcp_range->enable_discovery("false");
```

enable_immediate_discovery( )

Use this method to set or retrieve enable_immediate_discovery value of a DHCP Range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_immediate_discovery flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_immediate_discovery
my $enable_immediate_discovery = $dhcp_range->enable_immediate_discovery();
#Modify enable_immediate_discovery
$dhcp_range->enable_immediate_discovery("false");
```

email_list( )

Use this method to set or retrieve the email list to which the appliance sends notifications when DHCP address usage for the grid crosses a threshold.

If you enter email addresses in the email_list, then the appliance sends DHCP threshold alarms to the email addresses.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get email_list
my @email_list = $range->email_list();
#Modify email_list
$range->email_list( [ "admin\@test.com" ] );
```

enable_ddns( )

Use this method to set or retrieve the enable_ddns flag of a DHCP range.

Enable this method to allow dynamic DNS updates.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_ddns flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ddns
my $enable_ddns = $dhcp_range->enable_ddns();
#Modify enable_ddns
$dhcp_range->enable_ddns("false");
```

enable_dhcp_thresholds( )

Use this method to set or retrieve DHCP thresholds at the DHCP address range level. These thresholds are the high and low watermarks. If DHCP range usage goes above or below these percentage values, the Infoblox appliance generates a syslog message and sends an SNMP trap, if configured.

Enable this flag to set DHCP threshold values.

Parameter

Specify "true" to set the enable_dhcp_thresholds flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_dhcp_thresholds
my $enable_dhcp_thresholds = $range->enable_dhcp_thresholds();
#Modify enable_dhcp_thresholds
$range->enable_dhcp_thresholds("false");
```

enable_ifmap_publishing( )

Use this method to set or retrieve the ifmap publishing option of a DHCP Range object. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set ifmap publishing option or "false" to deactivate/unset it. The default value is 'false', which indicates that this attribute inherits the member level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ifmap_publishing
my $enable_ifmap_publishing = $dhcp_range->enable_ifmap_publishing()
# Modify enable_ifmap_publishing
$dhcp_range->enable_ifmap_publishing("true");
# Un-override enable_ifmap_publishing
$dhcp_range->enable_ifmap_publishing(undef);
```

enable_email_warnings( )

Use this method to enable the appliance to send email notifications when DHCP address usage crosses a high or low watermark threshold.

Enable this flag if you want the appliance to send DHCP threshold warnings to the "email_list" provided when DHCP threshold is enabled.

Parameter

Specify "true" to set the enable_email_warnings flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_email_warnings
my $enable_email_warnings = $range->enable_email_warnings();
#Modify enable_email_warnings
$range->enable_email_warnings("false");
```

enable_known_clients_option( )

Use this method to set or retrieve the enable_known_clients_option flag of a DHCP range.

You must set the enable_known_clients_option flag to true in order to use the known_clients_option attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_known_clients_option flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_known_clients_option
my $enable_known_clients_option = $dhcp_range->enable_known_clients_option();
#Modify enable_known_clients_option
$dhcp_range->enable_known_clients_option("false");
```

enable_snmp_warnings( )

Use this method to enable the appliance to send an SNMP trap when DHCP address usage crosses a watermark threshold.

If the flag is enabled, then the appliance sends SNMP traps when DHCP address usage crosses a watermark threshold when DHCP threshold is enabled.

Parameter

Specify "true" to set the enable_snmp_warnings flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_snmp_warnings
my $enable_snmp_warnings = $range->enable_snmp_warnings();
#Modify enable_snmp_warnings
$range->enable_snmp_warnings("false");
```

enable_unknown_clients_option( )

Use this method to set or retrieve the enable_unknown_clients_option flag of a DHCP range.

You must set the enable_unknown_clients_option flag to true in order to use the unknown_clients_option attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_unknown_clients_option flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_unknown_clients_option
my $enable_unknown_clients_option = $dhcp_range->enable_unknown_clients_option();
#Modify enable_unknown_clients_option
$dhcp_range->enable_unknown_clients_option("false");
```

end_addr( )

Use this method to set or retrieve the end address of the DHCP range.

An end address is the last IP address in the DHCP range available for the clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the end address of the DHCP range in IPv4 address format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get end_addr
my $end_addr = $dhcp_range->end_addr();
#Modify end_addr
$dhcp_range->end_addr("10.0.0.20");
```

endpoint_sources( )

Use this method to retrieve the list of endpoints that provide object data. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an array of Infoblox::CiscoISE::Endpoint objects.

Example

```
#Get endpoint_sources value
my $endpoint_sources = $object->endpoint_sources();
```

exclude( )

Use this method to set or retrieve the exclusion range of IP addresses in the DHCP range which should not be assigned to clients.

If static addresses in the middle of an DHCP range are assigned to certain hosts, those addresses can be excluded from the DHCP range using this method.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::ExclusionRange objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get exclude
my $ref_exclude = $dhcp_range->exclude();
#Modify exclude
$dhcp_range->exclude([$exl1]); #$exl1 is an Infoblox::DHCP::ExclusionRange object
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP range object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $dhcp_range->extattrs();
#Modify extattrs
$dhcp_range->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP range object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $dhcp_range->extensible_attributes();
#Modify extensible attributes
$dhcp_range->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

failover_assoc( )

Use this method to set or retrieve the failover peer association name of the DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

If the attribute is set, the server_association_type attribute will also be set to "FAILOVER" if the name is defined, or to "NONE" if the member is also undefined.

Parameter

Specify the failover peer association name in string format. The default value is undefined.

Use an empty string ('') to remove a failover peer association from the DHCP range. Using undef is deprecated and may be changed in the future.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get failover_assoc
my $failover_assoc = $dhcp_range->failover_assoc();
#Modify failover_assoc
$dhcp_range->failover_assoc("peer2");
#Remove failover_assoc (using undef for removal is deprecated)
$dhcp_range->failover_assoc("");
```

filters( )

Use this method to set or retrieve the filters of the DHCP range.

Filters are used to screen the address assignments if the addresses in the DHCP range needs to be assigned to specific hosts.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::FilterRule::MAC, Infoblox::DHCP::FilterRule::NAC, Infoblox::DHCP::FilterRule::RelayAgent, Infoblox::DHCP::FilterRule::Option, Infoblox::DHCP::FilterRule::Fingerprint objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get filters
my $ref_filters = $dhcp_range->filters();
#Modify filters
$dhcp_range->filters([$exl1]); #$exl1 is an Infoblox::DHCP::FilterRule::MAC,
Infoblox::DHCP::FilterRule::NAC, Infoblox::DHCP::FilterRule::RelayAgent,
Infoblox::DHCP::FilterRule::Option or Infoblox::DHCP::FilterRule::Fingerprint object.
```

ignore_id( )

Use this method to set or retrieve the ignore_id type of a DHCP range object. Indicates whether the appliance will ignore DHCP client IDs or MAC addresses. This setting overrides the upper-level settings.

Parameter

Valid values are 'NONE', 'CLIENT', or 'MACADDR'. The default is 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $dhcp_range->ignore_id();
# Modify attribute value
$dhcp_range->ignore_id('CLIENT');
#Un-override ignore_id
$dhcp_range->ignore_id(undef);
```

ignore_mac_addresses( )

Use this method to set or retrieve the ignore_mac_addresses list of a DHCP range object. A list of MAC addresses the appliance will ignore. This setting overrides the upper-level settings.

If you enter MAC addresses in the ignore_mac_addresses, then the appliance will ignore them. If you enter empty array, then the

appliance will ignore any MAC address.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $dhcp_range->ignore_mac_addresses();
# Modify attribute value
$dhcp_range->ignore_mac_addresses(["11::11::11::11::11::11"]);
```

is_split_scope( )

Use this method to retrieve the is_split_scope flag of the DHCP range. This flag is "true" when the range is part of a split scope.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get is_split_scope
my $is_split_scope = $dhcp_range->is_split_scope();
```

known_clients_option( )

Use this method to set or retrieve the known_clients_option option of a DHCP range.

Set this option to "Allow" or "Deny" to allow or prevent the allocation of an IP address from this pool to any client that has a host declaration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "Allow" or "Deny" to set the known_clients_option flag value. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get known_clients_option
my $known_clients_option = $dhcp_range->known_clients_option();
#Modify known_clients_option
$dhcp_range->known_clients_option("Deny");
```

lease_scavenge_time( )

Use this method to set or retrieve the lease_scavenge_time value of a DHCP Range object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_lease_scavenge_time method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_lease_scavenge_time attribute to "false".

Note that when lease_scavenge_time is set to a defined value and override_lease_scavenge_time is set to "false", the last operation takes precedence. Thus the sequence $object->lease_scavenge_time(604800); $object->override_lease_scavenge_time("false"); will set override_lease_scavenge_time to "false", and the sequence $object->override_lease_scavenge_time("false"); $object->lease_scavenge_time(604800); will result in override_lease_scavenge_time="true".

Parameter

An integer that specifies the period of time, in seconds, that free and backup leases remain in the database before they are automatically deleted. To disable lease scavenging, set the parameter to -1. The minimum positive value must be greater than 86400 seconds (1 day). The default value of this parameter is -1, which means that lease scavenging is disabled.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lease_scavenge_time
my $lease_scavenge = $dhcp_range->lease_scavenge_time();
#Modify lease_scavenge_time
$dhcp_range->lease_scavenge_time(30 * 24 * 60 * 60);
```

name( )

Use this method to set or retrieve a descriptive name for the range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The desired name in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $dhcp_range->name();
#Modify name
$dhcp_range->name("external");
```

next_available_ip( )

Use this method to get the next available IP `address(es)` in the DHCP range object that was retrieved. Note that to use this method, the object MUST be retrieved via a get or search call, or created with an add call.

Parameter

The method accepts the following optional parameters:

```
  requested_num - The number of IP addresses requested. It must be a value between 1 and 20,
inclusive.
  excluded - A reference to an array of addresses to be excluded from the results.
```

Returns

This method returns the next available IP `address(es)` in the range. If requested_num is not specified, a string with the next available address will be returned; otherwise, the method will return a reference to an array of addresses.

Within a DHCP Range object, the next available IP `address(es)` are the first addresses in this range that match all of the following rules:

```
   * Are not part of the passed 'excluded' parameter (if specified).
   * There is no fixed address or host address record matching this IP address
   * There is no unmanaged record matching this IP address
   * The IP address is not contained in any excluded range of this DHCP range
   * There is no active lease matching this IP address (Deleted leases in the recycle bin are not
considered.)
```

Example

```
# Retrieve a particular range
my @retrieved_objs = $session->get(
                        object     => "Infoblox::DHCP::Range",
                        start_addr => "10.0.0.20"
);

$dhcp_range = $retrieved_objs[0];

# Print the next available IP address in the range
print $dhcp_range->next_available_ip() . "\n";
```

```
# This will retrieve the next 10 available addresses and print the first one.
my $addressesref = $dhcp_range->next_available_ip(requested_num => 10);
print @$addressesref[0] . "\n";

# This will retrieve the next 10 available addresses and exclude a couple.
my $addressesref = $dhcp_range->next_available_ip(requested_num => 10, excluded => ["10.0.0.21",
"10.0.0.22"]);
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a DHCP shared network object. If this flag is set to false all the defined DHCP options will be returned to the client. This setting overrides the upper-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate/unset it. The default value is undefined which indicates that this attribute inherit the upper-level setting..

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $dhcp_range->ignore_dhcp_option_list_request();
# Un-override ignore_dhcp_option_list_request
$dhcp_range->ignore_dhcp_option_list_request(undef);
# Modify ignore_dhcp_option_list_request
$dhcp_range->ignore_dhcp_option_list_request("true");
```

member( )

Use this method to set or retrieve the member or Microsoft server that serves the DHCP range.

The member or Microsoft server that serves DHCP for this IP address range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

If the attribute is set, the server_association_type attribute will also be set to "MEMBER" if setting member to an Infoblox::DHCP::Member object, to "MS_SERVER" if setting member to an Infoblox::DHCP::MSServer object, or to "NONE" if failover_assoc is also empty.

Parameter

The valid value is a defined Infoblox::DHCP::Member or Infoblox::DHCP::MSServer object. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member
my $ref_member = $dhcp_range->member();
#Modify member
$dhcp_range->member($member1); #$member is an Infoblox::DHCP::Member object
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $dhcp_range->ms_ad_user_data();
```

ms_options( )

Use this method to set or retrieve the Microsoft server custom DHCP options that are associated with this DHCP range.

Note: You can set only options that are included in both the Microsoft server and NIOS predefined option definitions. Options that are not common to both are read only and cannot be modified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains defined Infoblox::DHCP::MSOption objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $ref_options = $dhcp_range->ms_options();
#Modify options
$dhcp_range->ms_options([$option12]); #$option12 is an Infoblox::DHCP::MSOption object
```

network( )

Use this method to set or retrieve the DHCP network of the address range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the address and netmask of network in CIDR format (example: 10.0.0.0/8).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network
my $network = $dhcp_range->network();
```

network_view( )

Use this method to set or retrieve the network view of the DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the DHCP range is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $dhcp_range->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$dhcp_range->network_view($nview);
```

nextserver( )

Use this method to set or retrieve the nextserver IP address which is the boot file server where the boot file is stored.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::Range->bootfile() and Infoblox::DHCP::Range->bootserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nextserver
my $nextserver = $dhcp_range->nextserver();
#Modify nextserver
$dhcp_range->nextserver("4.4.4.4");
#Un-override nextserver
$dhcp_range->nextserver(undef);
```

options( )

Use this method to set or retrieve the options of the DHCP range.

DHCP options describe network configuration settings and various services available on the network. Setting the DHCP options for the DHCP range overrides the options set at the network level.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::Option objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $ref_options = $dhcp_range->options();
#Modify options
$dhcp_range->options([$option12]); #$option12 is an Infoblox::DHCP::Option object
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Range.

Filters are used to screen address assignments in a DHCP Range if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $dhcp_range->logic_filters();
#Modify logic_filters
$dhcp_range->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an Infoblox::DHCP::Filter::MAC,
Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP range is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$dhcp_range->override_ddns_domainname( );
#Modifying override_ddns_domainname
$dhcp_range->override_ddns_domainname("true");
```

override_enable_ifmap_publishing( )

The override_enable_ifmap_publishing controls whether the enable_ifmap_publishing in the DHCP Range is used, instead of the grid default.

The override_enable_ifmap_publishing can be specified explicitly. It is also set implicitly when enable_ifmap_publishing is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for enable_ifmap_publishing. Set the parameter to "false" to inherit the grid-level setting for enable_ifmap_publishing.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_enable_ifmap_publishing
my $override_enable_ifmap_publishing=$dhcp_range->override_enable_ifmap_publishing( );
#Modifying override_enable_ifmap_publishing
$dhcp_range->override_enable_ifmap_publishing("true");
```

override_blackout_setting( )

The override_blackout_setting attribute controls whether the discovery_blackout_setting and port_control_blackout_setting values in the object are used, instead of the grid default.

The override_blackout_setting attribute can be specified explicitly. It is also set implicitly when discovery_blackout_setting or port_control_blackout_setting is set to a defined value.

Parameter

Specify "true" to set the override_blackout_setting flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $dhcp_range->override_blackout_setting();
# Modify attribute value
$dhcp_range->override_blackout_setting('true');
```

override_ignore_id( )

The override_ignore_id controls whether the ignore_id in the DHCP Range is used, instead of the upper-level default.

The override_ignore_id can be specified explicitly. It is also set implicitly when ignore_id is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ignore_id and ignore_mac_addresses. Set the parameter to "false" to inherit the upper-level setting for ignore_id and ignore_mac_addresses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$dhcp_range->override_ignore_id();
#Modifying attribute value
$dhcp_range->override_ignore_id('true');
```

override_lease_scavenge_time( )

The override_lease_scavenge_time attribute controls whether the lease_scavenge_time value in the DHCP range is used, instead of the upper-level default.

The override_lease_scavenge_time attribute can be specified explicitly. It is also set implicitly when lease_scavenge_time is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for lease_scavenge_time. Set the parameter to "false" to inherit the setting for lease_scavenge_time from the upper level.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_lease_scavenge_time
my $override_lease_scavenge_time=$dhcp_range->override_lease_scavenge_time( );
#Modifying override_lease_scavenge_time
$dhcp_range->override_lease_scavenge_time("true");
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value in the DHCP Range is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$dhcp_range->override_logic_filters( );
#Modifying override_logic_filters
$dhcp_range->override_logic_filters("true");
```

override_subscribe_settings( )

The override_subscribe_settings attribute controls whether the subscribe_settings method values of the member are used, instead of the Grid default.

The override_subscribe_settings attribute can be specified explicitly. It is also set implicitly when subscribe_settings is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for subscribe_settings. Set the parameter to "false" to inherit the Grid-level setting for subscribe_settings.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_subscribe_settings value
my $override_subscribe_settings = $object->override_subscribe_settings( );
#Modify override_subscribe_settings value
$object->override_subscribe_settings("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP range is used, instead of the grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_update_dns_on_lease_renewal
my $override_update_dns_on_lease_renewal=$dhcp_range->override_update_dns_on_lease_renewal( );
#Modifying override_update_dns_on_lease_renewal
$dhcp_range->override_update_dns_on_lease_renewal("true");
```

port_control_blackout_setting

Use this method to set or retrieve the port control blackout setting.

Setting this method to a defined value implicitly sets the override_blackout_setting method to "true". If discovery_blackout_setting is undefined, setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_blackout_setting attribute to "false".

Note that when port_control_blackout_setting is set to a defined value and override_blackout_setting is set to "false", the last operation takes precedence. Thus the sequence $network->port_control_blackout_setting($blackout); $network->override_blackout_setting("false"); will set override_blackout_setting to "false", and the sequence $network->override_blackout_setting("false"); $network->port_control_blackout_setting($blackout); will result in override_blackout_setting="true".

Parameter

Valid value is an Infoblox::Grid::Discovery::Properties::BlackoutSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get port_control_blackout_setting
my $port_control_blackout_setting = $dhcp_range->port_control_blackout_setting();
#Modify port_control_blackout_setting
$dhcp_range->port_control_blackout_setting($blackout);
```

pxe_lease_time( )

Use this method to set or retrieve PXE Lease Time value of the DHCP range.

The Preboot Execution Environment Lease Time value is used by some hosts to boot remotely from a server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) represents the duration in seconds that the record is cached. Zero indicates that the record should not be cached. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get pxe_lease_time
my $pxe_lease_time = $dhcp_range->pxe_lease_time();
#Modify pxe_lease_time
$dhcp_range->pxe_lease_time("7200");
```

range_high_water_mark( )

Use this method to set or retrieve the range_high_water_mark value. If the percentage of allocated addresses exceeds this value, an SNMP trap is sent, unless this is a range served by a Microsoft server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The high watermark value must be greater than the low watermark value. The default value is 95.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_high_water_mark
my $range_high_water_mark = $range->range_high_water_mark();
#Modify range_high_water_mark
$range->range_high_water_mark(80);
```

range_high_water_mark_reset( )

Use this method to set or retrieve the range_high_water_mark_reset value. If the percentage of allocated addresses drops below this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The high watermark reset value must be lower than the high watermark value. The default value is 85.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_high_water_mark_reset
my $range_high_water_mark_reset = $range->range_high_water_mark_reset();
#Modify range_high_water_mark_reset
$range->range_high_water_mark_reset(70);
```

range_low_water_mark( )

Use this method to set or retrieve the range_low_water_mark value. If the percentage of allocated addresses drops below this watermark, an SNMP trap is sent, unless this is a range served by a Microsoft server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The low watermark value must be lower than the high watermark value. The default low watermark number is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_low_water_mark
my $range_low_water_mark = $range->range_low_water_mark();
#Modify range_low_water_mark
$range->range_low_water_mark(10);
```

range_low_water_mark_reset( )

Use this method to set or retrieve the range_low_water_mark_reset value. If the percentage of allocated addresses exceeds this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The low watermark reset value must be higher than the low watermark value. The default low watermark reset number is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_low_water_mark_reset
```

```
my $range_low_water_mark_reset = $range->range_low_water_mark_reset();
#Modify range_low_water_mark_reset
$range->range_low_water_mark_reset(10);
```

restart_if_needed( )

Use this method to set the flag that indicates whether DHCP service should be restarted on a member that is serving DHCP for the changed object referenced in a cloud API request.

Parameter

Specify true to restart the DHCP service.

Returns

None

Example

```
# Modify
$network->restart_if_needed('true');
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag of the DHCP range.

If the flag is enabled, the leases are kept in recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Parameter

Specify "true" to set the recycle_leases flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $dhcp_range->recycle_leases();
#Modify recycle_leases
$dhcp_range->recycle_leases("false");
```

same_port_control_discovery_blackout( )

Use this method to set or retrieve the flag that enables using the same discovery blackout for port control blackout.

Parameter

Specify 'true' to use same discovery blackout for port control blackout or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $dhcp_range->same_port_control_discovery_blackout();
# Modify attribute value
$dhcp_range->same_port_control_discovery_blackout('true');
```

server_association_type( )

Use this method to set or retrieve the DHCP range server association type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The server_association_type attribute can be specified explicitly. It is also set implicitly when member or failover_assoc are set.

Parameter

Valid values are "NONE", "FAILOVER", "MS_SERVER" and "MEMBER".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get server_association_type
my $server_association_type = $dhcp_range->server_association_type();
#Modify server_association_type
$dhcp_range->server_association_type("MEMBER");
```

split_member

Use this method to set the address or FQDN of the Microsoft server that is serving the split scope. Note that this method applies only when the range is first added.

Include the specified parameter to set the attribute value.

Parameter

The valid value is a defined Infoblox::DHCP::MSServer object. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set split_member prior to the range insertion
$dhcp_range->split_member($member); #$member is an Infoblox::DHCP::Member object
```

split_scope_exclusion_percent

Use this method to set the percentage for the split scope exclusion. For example, if this is set to 40, then 60% of the range will be assigned to the Microsoft server specified in split_member. Note this method has an effect only when the range is first added.

Include the specified parameter to set the attribute value.

Parameter

An unsigned integer between 1 and 99. The default is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set split_scope_exclusion_percent prior to the range insertion
$dhcp_range->split_scope_exclusion_percent(35);
```

start_addr( )

Use this method to set or retrieve the start address of the DHCP range.

A start address is the first IP address in the DHCP range available for the clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the start address of the DHCP range in IPv4 address format. An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get start_addr
my $start_addr = $dhcp_range->start_addr();
#Modify start_addr
$dhcp_range->start_addr("10.0.0.2");
```

subscribe_settings( )

Use this method to set or retrieve the Cisco ISE subscribe settings.

Setting this method to a defined value implicitly sets the override_subscribe_settings method to "true". Setting the parameter to undefined causes the appliance to use the Cisco ISE endpoint default and automatically resets the override_subscribe_settings method to "false".

Note that when subscribe_settings is set to a defined value and override_subscribe_settings is set to "false", the last operation takes precedence. Thus the sequence $object->subscribe_settings($value); $object->override_subscribe_settings("false"); will set override_subscribe_settings to "false", and the sequence $object->override_subscribe_settings("false"); $object->subscribe_settings($value); will result in override_subscribe_settings="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an Infoblox::CiscoISE::SubscribeSetting object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get subscribe_settings value
my $subscribe_settings = $object->subscribe_settings();
#Modify subscribe_settings value
$object->subscribe_settings($settings);
```

template( )

Use this method to set or retrieve the DHCP range template name for a DHCP Range object.

Template is the name of a DHCP range template which will be used to create the DHCP range.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid name in sting format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

The template parameter can be used to only add a new DHCP range and cannot be used during object modify or returned during object get.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get template
my $template = $dhcp_range->template();
#Modify template
$dhcp_range->template("Template_Name");
```

unknown_clients_option( )

Use this method to set or retrieve the unknown_clients_option option of a DHCP range.

Set this option to "Allow" or "Deny" to allow or prevent the allocation of an IP address from this pool to any client that has no host declaration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "Allow" or "Deny" to set the unknown_clients_option flag value. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get unknown_clients_option
my $unknown_clients_option = $dhcp_range->unknown_clients_option();
#Modify unknown_clients_option
$dhcp_range->unknown_clients_option("Deny");
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$dhcp_range->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$dhcp_range->update_dns_on_lease_renewal("true");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP range object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP Range object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a DHCP Member object
my $memberdhcp = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2"
);
unless($memberdhcp) {
       die("Construct member failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Member object created successfully\n";

#Create the Network object with the member
```

```
my $network = Infoblox::DHCP::Network->new(
    network => "10.0.0.0/8",
    comment => "add network",
    members => [ $memberdhcp ]
);
unless($network) {
       die("Construct Network object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network object created successfully\n";

#Add the Network object into the Infoblox appliance through a session
$session->add($network)
    or die("Add Network object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "Network object added to Infoblox appliance successfully\n";

#Create the Mac Filter object
my $mac_filter = Infoblox::DHCP::Filter::MAC->new(
    "name"    => "filter1",
    "comment" => "5 minutes"
);

unless($mac_filter) {
       die("Construct Mac Filter object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Mac Filter object created successfully\n";

#Add the Mac Filter object into the Infoblox appliance through a session
$session->add($mac_filter)
    or die("Add Mac Filter object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "Mac Filter object added to Infoblox appliance successfully\n";

#Construct Custom Option object
my $option1 = Infoblox::DHCP::Option->new(
    type  => "1",
    value => "255.0.0.0", );

#Construct DHCP Mac Filter rule object
my $filter = Infoblox::DHCP::FilterRule::MAC->new(
    filter_name => "filter1",
    permission  => "grant"
);

#Construct exclusion range object
my $exclusion_range = Infoblox::DHCP::ExclusionRange->new(
    start_address => "10.0.0.5",
    end_address   => "10.0.0.7",
    comment       => "Excluded range"
);
```

#Create a DHCP Range object

```
my $dhcp_range = Infoblox::DHCP::Range->new(
        end_addr                => "10.0.0.10",
        network                 => "10.0.0.0/8",
        start_addr              => "10.0.0.1",
        bootfile                => "bootfile1.com",
        bootserver              => "someserver.com",
        comment                 => "add range",
        ddns_generate_hostname  => "true",
        deny_all_clients        => "true",
        deny_bootp              => "true",
        disable                 => "true",
        enable_ddns             => "true",
        exclude                 => [$exclusion_range],
        filters                 => [$filter],
        member                  => $memberdhcp,
        nextserver              => "3.3.3.3",
        options                 => [$option1],
        pxe_lease_time          => "3600",
        recycle_leases          => "true",
);
unless($dhcp_range) {
```

```
        die("Construct DHCP Range object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Range object created successfully\n";

#Add the DHCP Range object into the Infoblox appliance through a session
$session->add($dhcp_range)
    or die("Add DHCP Range object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Range object added to the network successfully\n";
```

#Create a DHCP Range object using a template

```
my $dhcp_range_template = Infoblox::DHCP::RangeTemplate->new(
        name                    => "custom_range_template",
        offset                  => "10",
        number_of_addresses     => "10",
);
unless($dhcp_range_template) {
        die("Construct DHCP Range template object failed: ",

NAME

Infoblox::DHCP::RangeTemplate - DHCP RangeTemplate object.

DESCRIPTION

A DHCP range template works as a 'cookie cutter' and can be used to create real DHCP range object in a quick and consistent way. The DHCP range object created from a DHCP range template will inherit most properties defined in range template object. So, most of the DHCP range template properties are the same as the DHCP range object properties.

CONSTRUCTOR

```
my $dhcp_range_template = Infoblox::DHCP::RangeTemplate->new(
```

```
     name                                => $string,
# Required
     number_of_addresses                 => $num,
# Required
     offset                              => $num,
# Required
     bootfile                            => $filename,
# Optional / Default is undefined
     bootserver                          => $ipv4addr | $fqdn | undef,
# Optional / Default is undefined
     comment                             => $string,
# Optional / Default is undefined
     ddns_domainname                     => $string | undef,

# Optional / Default value is "false"
     override_lease_scavenge_time        => "true" | "false",
# Optional / Default value is "false"
     override_update_dns_on_lease_renewal => "true" | "false",
# Optional / Default value is "false"
     pxe_lease_time                      => $num,
# Optional / Default is undefined
     range_high_water_mark               => $num,
# Optional / Default is 95
     range_high_water_mark_reset         => $num,
# Optional / Default is 95
     range_low_water_mark                => $num,
# Optional / Default is 0
     range_low_water_mark_reset          => $num,
# Optional / Default is 0
     recycle_leases                      => "true" | "false",
# Optional / Default is undefined
     server_association_type             => "NONE" | "MEMBER" | "FAILOVER" | "MS_SERVER"
# Optional / Default is undefined
     unknown_clients_option              => "Allow" | "Deny",
# Optional / Default is undefined
     update_dns_on_lease_renewal         => "true" | "false",
# Optional / Default value is "false"
      );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

MODULE METHODS

The following functions are available to be applied to a DHCP Range Template object.

Infoblox::DHCP::NetworkTemplate->range_templates( )

Use this function to specify a range template at network template on the Infoblox appliance. See Infoblox::DHCP::NetworkTemplate->range_templates() for parameters and return values.

Example

```
#Construct a range template object
my $dhcp_range_template = Infoblox::DHCP::RangeTemplate->new(
            name                    => "custom_range_template",
            number_of_addresses     => "10",
            offset                  => "10",
    );

my $template = Infoblox::DHCP::Template->new(
            name                    => "custom_range_template",
    );

#Configure range template in network template object
my $responce = $network_template->range_templates([$template]);
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that can be applied to a DHCP range template object.

Infoblox::Session->add( )

Use this method to add a DHCP range template object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $dhcp_range_template = Infoblox::DHCP::RangeTemplate->new(
        name                    => "custom_range_template",
        number_of_addresses     => "10",
        offset                  => "10",
        bootfile                => "bootfile1.com",
        bootserver              => "someserver.com",
        comment                 => "add range",
        ddns_generate_hostname  => "true",
        deny_all_clients        => "true",
        deny_bootp              => "true",
        enable_ddns             => "true",
        exclude                 => [$exclusion_range_template],
        filters                 => [$filter],
        member                  => $memberdhcp,
        nextserver              => "3.3.3.3",
        options                 => [$option1],
        pxe_lease_time          => "3600",
        recycle_leases          => "true",
);

# Submit for addition
my $response = $session->add( $dhcp_range_template );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP range template object:

name - Optional. The name of the DHCP range template.
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
server_association_type - Optional. The server association type for the range.
```

Examples

```
my @retrieved_objs = $session->get(
                        object => "Infoblox::DHCP::RangeTemplate",
                        name   => "custom_range_template"
                        );
```

```
my @retrieved_objs = $session->get(
                      object               => "Infoblox::DHCP::RangeTemplate",
                      extensible_attributes => { 'Site' => 'Santa Clara' }
                     );
```

Infoblox::Session->search( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific DHCP Range Template object:

name    - Optional. The name of the DHCP range template (regular expression).
comment - Optional. The comment of the DHCP range template (regular expression).
extattrs     - Optional. A hash reference containing extensible attributes.
extensible_attributes - Optional. A hash reference containing extensible attributes.
server_association_type - Optional. The server association type for the range.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
my @retrieved_objs = $session->search(
                      object  => "Infoblox::DHCP::RangeTemplate",
                      name    => "custom_range_template"
           comment => ".*",
       );

my @retrieved_objs = $session->search(
                      object               => "Infoblox::DHCP::RangeTemplate",
                      extensible_attributes => { 'Site' => 'Santa Clara' }
       );
```

Infoblox::Session->modify( )

Use this method to modify a DHCP range template object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use method to modify the comment.
$dhcp_range_template->comment("this is a modified comment");
# Submit modification
my $response = $session->modify( $dhcp_range_template );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP range template object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP range template object, and then submit this object for removal.

Example

```
# Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::RangeTemplate",
    name   => "custom_range_template"
    );

# Find the desired object from the retrieved list.
my $desired_dhcp_range_template = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove( $desired_dhcp_range_template );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP range template object.

bootfile( )

Use this method to set or retrieve a bootfile name which is the name of the file the client must download.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::RangeTemplate->bootserver() and Infoblox::DHCP::RangeTemplate->nextserver().

Parameter

The boot file name in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootfile
my $bootfile = $dhcp_range_template->bootfile();
#Modify bootfile
$dhcp_range_template->bootfile("bootfile2.com");
#Un-override bootfile
$dhcp_range_template->bootfile(undef);
```

bootserver( )

Use this method to set or retrieve a bootserver name which is the name of the server where the boot file is stored.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::RangeTemplate->bootfile() and Infoblox::DHCP::RangeTemplate->nextserver().

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootserver
my $bootserver = $dhcp_range_template->bootserver();
#Modify bootserver
$dhcp_range_template->bootserver("anotherserver.com");
#Un-override bootserver
$dhcp_range_template->bootserver(undef);
```

comment( )

Use this method to set or retrieve a descriptive comment of a DHCP range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $dhcp_range_template->comment();
#Modify comment
$dhcp_range_template->comment("Modifying the DHCP range template comment");
```

ddns_domainname( )

Use this method to set or retrieve the ddns_domainname value of a DHCP Range template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_dddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

The dynamic DNS domain name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_domainname
my $ddns_domainname = $dhcp_range_template->ddns_domainname();
#Modify ddns_domainname
$dhcp_range_template->ddns_domainname("test_domain.com");
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a DHCP range template.

Enable this method to allow only the DHCP server to generate a hostname.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ddns_generate_hostname flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_generate_hostname
my $ddns_generate_hostname = $dhcp_range_template->ddns_generate_hostname();
#Modify ddns_generate_hostname
$dhcp_range_template->ddns_generate_hostname("false");
```

deny_all_clients( )

Use this method to set or retrieve the deny_all_clients flag of a DHCP range template.

Enable this method to deny all lease requests for the DHCP range created from template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_all_clients flag or "false" to deactivate/unset it. The default value for this field is false.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_all_clients
my $deny_all_clients = $dhcp_range_template->deny_all_clients();
#Modify deny_all_clients
$dhcp_range_template->deny_all_clients("false");
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP range template.

Enable this method to deny all BOOTP requests for DHCP range created from this template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is false which indicates that this attribute inherit the upper-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $dhcp_range_template->deny_bootp();
#Modify deny_bootp
$dhcp_range_template->deny_bootp("false");
```

enable_ddns( )

Use this method to set or retrieve the enable_ddns flag of a DHCP range template.

Enable this method to allow dynamic DNS updates.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_ddns flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ddns
my $enable_ddns = $dhcp_range_template->enable_ddns();
#Modify enable_ddns
$dhcp_range_template->enable_ddns("false");
```

enable_known_clients_option( )

Use this method to set or retrieve the enable_known_clients_option flag of a DHCP range.

You must set the enable_known_clients_option flag to true in order to use the known_clients_option attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_known_clients_option flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_known_clients_option
my $enable_known_clients_option = $dhcp_range->enable_known_clients_option();
#Modify enable_known_clients_option
$dhcp_range->enable_known_clients_option("false");
```

enable_unknown_clients_option( )

Use this method to set or retrieve the enable_unknown_clients_option flag of a DHCP range.

You must set the enable_unknown_clients_option flag to true in order to use the unknown_clients_option attribute.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_unknown_clients_option flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_unknown_clients_option
my $enable_unknown_clients_option = $dhcp_range->enable_unknown_clients_option();
#Modify enable_unknown_clients_option
$dhcp_range->enable_unknown_clients_option("false");
```

exclude( )

Use this method to set or retrieve the exclusion range template in the DHCP range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::ExclusionRangeTemplate objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    #Get exclude
    my $ref_exclude = $dhcp_range_template->exclude();
    #Modify exclude
    $dhcp_range_template->exclude([$exl1]); #$exl1 is an Infoblox::DHCP::ExclusionRangeTemplate
object
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Range Template object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $dhcp_range_template->extattrs();
#Modify extattrs
$dhcp_range_template->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Range Template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $dhcp_range_template->extensible_attributes();
#Modify extensible attributes
$dhcp_range_template->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

failover_assoc( )

Use this method to set or retrieve the failover peer association name of the DHCP range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

If the attribute is set, the server_association_type attribute will also be set to "FAILOVER" if the name is defined, or to "NONE" if the member is also undefined.

Parameter

Specify the failover peer association name in string format. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get failover_assoc
my $failover_assoc = $dhcp_range_template->failover_assoc();
#Modify failover_assoc
$dhcp_range_template->failover_assoc("peer2");
```

filters( )

Use this method to set or retrieve the filters of the DHCP range template.

Filters are used to screen the address assignments if the addresses in the DHCP range needs to be assigned to specific hosts.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains defined Infoblox::DHCP::FilterRule::MAC, Infoblox::DHCP::FilterRule::NAC, Infoblox::DHCP::FilterRule::RelayAgent, Infoblox::DHCP::FilterRule::Fingerprint and Infoblox::DHCP::FilterRule::UserClass objects. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get filters
my $ref_filters = $dhcp_range_template->filters();
#Modify filters
$dhcp_range_template->filters([$filter1]); #$filter1 is an Infoblox::DHCP::FilterRule::MAC,
Infoblox::DHCP::FilterRule::MAC,  Infoblox::DHCP::FilterRule::RelayAgent,
Infoblox::DHCP::FilterRule::Fingerprint or Infoblox::DHCP::FilterRule::UserClass object.
```

known_clients_option( )

Use this method to set or retrieve the known_clients_option option of a DHCP range.

Set this option to "Allow" or "Deny" to allow or prevent the allocation of an IP address from this pool to any client that has a host declaration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "Allow" or "Deny" to set the known_clients_option flag value. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get known_clients_option
my $known_clients_option = $dhcp_range->known_clients_option();
#Modify known_clients_option
$dhcp_range->known_clients_option("Deny");
```

lease_scavenge_time( )

Use this method to set or retrieve the lease_scavenge_time value of a DHCP Range Template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_lease_scavenge_time method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_lease_scavenge_time attribute to "false".

Note that when lease_scavenge_time is set to a defined value and override_lease_scavenge_time is set to "false", the last operation takes precedence. Thus the sequence $object->lease_scavenge_time(604800); $object->override_lease_scavenge_time("false"); will set override_lease_scavenge_time to "false", and the sequence $object->override_lease_scavenge_time("false"); $object->lease_scavenge_time(604800); will result in override_lease_scavenge_time="true".

Parameter

An integer that specifies the period of time, in seconds, that free and backup leases remain in the database before they are automatically deleted. To disable lease scavenging, set the parameter to -1. The minimum positive value must be greater than 86400 seconds (1 day). The default value of this parameter is -1, which means that lease scavenging is disabled.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lease_scavenge_time
my $lease_scavenge = $dhcp_range_template->lease_scavenge_time();
#Modify lease_scavenge_time
$dhcp_range_template->lease_scavenge_time(30 * 24 * 60 * 60);
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Range Template object.

Filters are used to screen address assignments in a DHCP Range Template if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $dhcp_range_template->logic_filters();
#Modify logic_filters
$dhcp_range_template->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an
Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

member( )

Use this method to set or retrieve the member or Microsoft (r) server of the DHCP range template.

The member or Microsoft server that serves DHCP for this IP address range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

If the attribute is set, the server_association_type attribute will also be set to "MEMBER" if you set the member to an Infoblox::DHCP::Member object, to "MS_SERVER" if you set the member to an Infoblox::DHCP::MSServer object, or to "NONE" if failover_assoc is also empty.

Parameter

The valid value is a defined Infoblox::DHCP::Member or Infoblox::DHCP::MSServer object. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get member
my $ref_member = $dhcp_range_template->member();
#Modify member
$dhcp_range_template->member($member1); #$member is an Infoblox::DHCP::Member object
```

name( )

Use this method to set or retrieve the description of the name of the DHCP range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Name of the fixed address in string format with a maximum of 64 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $dhcp_range_template->name();
#Modify name
$dhcp_range_template->name("custom_range_template");
```

nextserver( )

Use this method to set or retrieve the nextserver IP address which is the boot file server where the boot file is stored.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::RangeTemplate->bootfile() and Infoblox::DHCP::RangeTemplate->bootserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nextserver
my $nextserver = $dhcp_range_template->nextserver();
#Modify nextserver
$dhcp_range_template->nextserver("4.4.4.4");
#Un-override nextserver
$dhcp_range_template->nextserver(undef);
```

number_of_addresses( )

Use this method to set or retrieve the number of addresses in this DHCP range template

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of addresses in this DHCP range template.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get number_of_addresses
my $number_of_addresses = $dhcp_range_template-> number_of_addresses();
#Modify number_of_addresses
$dhcp_range_template->number_of_addresses("10");
```

offset( )

Use this method to set or retrieve the address offset of this DHCP range template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The address offset of this DHCP range template. The offset is calculated from the start address of network template to which the DHCP range template is assigned to. For example, if offset is set to 10 and number_of_addresses is set to 100, and network is set to 10.0.0.0/8, then start address of DHCP range created from this range template will be 10.0.0.10 and end address will be 10.0.0.100.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get offset
my $offset = $dhcp_range_template->offset();
#Modify offset
$dhcp_range_template->offset("10");
```

options( )

Use this method to set or retrieve the options of the DHCP range template.

DHCP options describe network configuration settings and various services available on the network.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::Option objects. The default value is empty.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $ref_options = $dhcp_range_template->options();
#Modify options
$dhcp_range_template->options([$option12]); #$option12 is an Infoblox::DHCP::Option object
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP range template is used, instead of the Grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$dhcp_range_template->override_ddns_domainname( );
#Modifying override_ddns_domainname
$dhcp_range_template->override_ddns_domainname("true");
```

override_lease_scavenge_time( )

The override_lease_scavenge_time attribute controls whether the lease_scavenge_time value in the DHCP range template is used, instead of the upper-level default.

The override_lease_scavenge_time attribute can be specified explicitly. It is also set implicitly when lease_scavenge_time is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for lease_scavenge_time. Set the parameter to "false" to inherit the setting for lease_scavenge_time from the upper level.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_lease_scavenge_time
my $override_lease_scavenge_time=$dhcp_range_template->override_lease_scavenge_time( );
#Modifying override_lease_scavenge_time
$dhcp_range_template->override_lease_scavenge_time("true");
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value in the DHCP Range Template is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$dhcp_range_template->override_logic_filters( );
#Modifying override_logic_filters
$dhcp_range_template->override_logic_filters("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP range template is used, instead of the Grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    #Getting override_update_dns_on_lease_renewal
    my $override_update_dns_on_lease_renewal=$dhcp_range_template-
>override_update_dns_on_lease_renewal( );
    #Modifying override_update_dns_on_lease_renewal
    $dhcp_range_template->override_update_dns_on_lease_renewal("true");
```

pxe_lease_time( )

Use this method to set or retrieve the PXE lease time value of the DHCP range template.

The Preboot Execution Environment lease time value is used by some hosts to boot remotely from a server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) represents the duration in seconds that the record is cached. Zero indicates that the record should not be cached. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get pxe_lease_time
my $pxe_lease_time = $dhcp_range_template->pxe_lease_time();
#Modify pxe_lease_time
$dhcp_range_template->pxe_lease_time("7200");
```

range_high_water_mark( )

Use this method to set or retrieve the range_high_water_mark value. If the percentage of allocated addresses exceeds this value, an

SNMP trap is sent, unless this is a range served by a Microsoft server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The high watermark value must be greater than the low watermark value. The default value is 95.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_high_water_mark
my $dhcp_range_template_high_water_mark = $dhcp_range_template->range_high_water_mark();
#Modify range_high_water_mark
$dhcp_range_template->range_high_water_mark(80);
```

range_high_water_mark_reset( )

Use this method to set or retrieve the range_high_water_mark_reset value. If the percentage of allocated addresses drops below this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The high watermark reset value must be lower than the high watermark value. The default value is 95.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_high_water_mark_reset
my $dhcp_range_template_high_water_mark_reset = $dhcp_range_template->range_high_water_mark_reset();
#Modify range_high_water_mark_reset
$dhcp_range_template->range_high_water_mark_reset(70);
```

range_low_water_mark( )

Use this method to set or retrieve the range_low_water_mark value. If the percentage of allocated addresses drops below this watermark, an SNMP trap is sent, unless this is a range served by a Microsoft server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The low watermark value must be lower than the high watermark value. The default low watermark value is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_low_water_mark
my $dhcp_range_template_low_water_mark = $dhcp_range_template->range_low_water_mark();
#Modify range_low_water_mark
$dhcp_range_template->range_low_water_mark(10);
```

range_low_water_mark_reset( )

Use this method to set or retrieve the range_low_water_mark_reset value. If the percentage of allocated addresses exceeds this value, a corresponding SNMP trap is reset.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A number that specifies the percentage of allocated addresses. The range is from 1 to 100. The low watermark reset value must be higher than the low watermark value. The default low watermark reset number is 0.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get range_low_water_mark_reset
my $dhcp_range_template_low_water_mark_reset = $dhcp_range_template->range_low_water_mark_reset();
#Modify range_low_water_mark_reset
$dhcp_range_template->range_low_water_mark_reset(10);
```

server_association_type( )

Use this method to set or retrieve the DHCP range template server association type.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The server_association_type attribute can be specified explicitly. It is also set implicitly when member or failover_assoc are set.

Parameter

Valid values are "NONE", "FAILOVER", "MS_SERVER" and "MEMBER".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get server_association_type
my $server_association_type = $dhcp_range_template->server_association_type();
#Modify server_association_type
$dhcp_range_template->server_association_type("MEMBER");
```

recycle_leases( )

Use this method to set or retrieve the recycle_leases flag of the DHCP range template.

If the flag is enabled, the leases are kept in recycle bin until one week after expiration. When the flag is disabled, the leases are irrecoverably deleted.

Parameter

Specify "true" to set the recycle_leases flag or "false" to deactivate/unset it. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get recycle_leases
my $recycle_leases = $dhcp_range_template->recycle_leases();
#Modify recycle_leases
$dhcp_range_template->recycle_leases("false");
```

unknown_clients_option( )

Use this method to set or retrieve the unknown_clients_option option of a DHCP range.

Set this option to "Allow" or "Deny" to allow or prevent the allocation of an IP address from this pool to any client that has no host declaration.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "Allow" or "Deny" to set the unknown_clients_option flag value. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get unknown_clients_option
my $unknown_clients_option = $dhcp_range->unknown_clients_option();
#Modify unknown_clients_option
$dhcp_range->unknown_clients_option("Deny");
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$dhcp_range_template->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$dhcp_range_template->update_dns_on_lease_renewal("true");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP range template object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP RangeTemplate object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $host_ip = "192.168.1.2";
my $session = Infoblox::Session->new(
               master   => $host_ip,      #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);
unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create a DHCP Member object
my $memberdhcp = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => $host_ip
);
```

```
unless($memberdhcp) {
       die("Construct member failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Member object created successfully\n";

#Create the Mac Filter object
my $mac_filter = Infoblox::DHCP::Filter::MAC->new(
    name    => "filter1",
    comment => "5 minutes"
);

unless($mac_filter) {
       die("Construct Mac Filter object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Mac Filter object created successfully\n";

#Add the Mac Filter object into the Infoblox appliance through a session
$session->add($mac_filter)
    or die("Add Mac Filter object failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "Mac Filter object added to Infoblox appliance successfully\n";

#Construct DHCP Mac Filter rule object
my $filter = Infoblox::DHCP::FilterRule::MAC->new(
    filter_name => "filter1",
    permission  => "grant"
);
unless($filter){
   die("Construct filter object failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
   }
 print "Filter object created successfully\n";

#Construct exclusion range template object
my $exclusion_range_template = Infoblox::DHCP::ExclusionRangeTemplate->new(
    offset              => "15",
    number_of_addresses => "5",
    comment             => "Excluded range"
);
unless($exclusion_range_template){
       die("Construct exclusion range template object failed: ",
                Infoblox::status_code() . ":" . Infoblox::status_detail());
       }
 print "Exclusion range template object created successfully\n";
```

#Create a DHCP RangeTemplate object

```
my $dhcp_range_template = Infoblox::DHCP::RangeTemplate->new(
        name                    => "custom_range_template",
        offset                  => "10",
        number_of_addresses     => "10",
        bootfile                => "bootfile1.com",
        bootserver              => "someserver.com",
        comment                 => "add range",
        ddns_generate_hostname  => "true",
        deny_all_clients        => "true",
        deny_bootp              => "true",
        enable_ddns             => "true",
        exclude                 => [$exclusion_range_template],
        filters                 => [$filter],
        member                  => $memberdhcp,
        nextserver              => "3.3.3.3",
        pxe_lease_time          => "3600",
        recycle_leases          => "true",
);
unless($dhcp_range_template) {
       die("Construct DHCP RangeTemplate object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP RangeTemplate object created successfully\n";

#Add the DHCP RangeTemplate object into the Infoblox appliance through a session
$session->add($dhcp_range_template)
```

```
    or die("Add DHCP RangeTemplate object failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "DHCP RangeTemplate object added to the network successfully\n";
```

#Search a DHCP RangeTemplate

```
#Search a DHCP RangeTemplate through the session
my @retrieved_objs = $session->search(
    object     => "Infoblox::DHCP::RangeTemplate",
    name       => "custom_range_template",
);
my $object = $retrieved_objs[0];
unless ($object) {
       die("Search DHCP RangeTemplate failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Search DHCP RangeTemplate object found at least 1 matching entry\n";
```

#Get and modify a DHCP RangeTemplate

```
#Get a DHCP RangeTemplate through the session
my @retrieved_objs = $session->get(
    object     => "Infoblox::DHCP::RangeTemplate",
    name       => "custom_range_template",
);
my $object = $retrieved_objs[0];
unless ($object) {
       die("Get DHCP RangeTemplate failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get DHCP RangeTemplate object found at least 1 matching entry\n";

#Modify one of the attributes of the specified DHCP RangeTemplate
$object->comment("modified comment");

#Un-override bootfile
$object->bootfile(undef);

#Un-override bootserver
$object->bootserver(undef);

#Un-override nextserver
$object->nextserver(undef);

#Apply the changes
$session->modify($object)
    or die("Modify DHCP Range Template failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "DHCP RangeTemplate object modified successfully \n";
```

#Remove a DHCP RangeTemplate

```
#Get a DHCP RangeTemplate through the session
my @retrieved_objs = $session->get(
    object     => "Infoblox::DHCP::RangeTemplate",
    name       => "custom_range_template",
);

my $object = $retrieved_objs[0];
unless ($object) {
       die("Get DHCP Range Template failed: ",
            $session->status_code() . ":" . $session->status_detail());
}
print "Get DHCP RangeTemplate object found at least 1 matching entry\n";

#submit the object for removal
$session->remove($object)
    or die("Remove DHCP Range Template failed: ",
            $session->status_code() . ":" . $session->status_detail());

print "DHCP Range Template object removed successfully \n";

NAME

Infoblox::DHCP::RoamingHost - DHCP Roaming Host object.

DESCRIPTION

A Roaming Host is a specific host that a DHCP server always assigns when a lease request comes from a particular MAC address of the client.

CONSTRUCTOR

```
my $roaming_host = Infoblox::DHCP::RoamingHost -> new(
      name                          => $string,                        #Required
      address_type                  => "ipv4" | "ipv6" | "both",       #Optional / Default is "ipv4"
      bootfile                      => $filename,                      #Optional / Default is empty
      bootserver                    => $ipv4addr,                      #Optional / Default is empty
      client_identifier_prepend_zero  => "true" | "false",             #Optional / Default is "false"
      comment                       => $string,                        #Optional / Default is empty
      ddns_domainname               => $string,                        #Optional / Default is empty
      ddns_hostname                 => $string,                        #Optional / Default is empty
      deny_bootp                    => "true" | "false",               #Optional / Default is "false"
      dhcp_client_identifier        => $string,                        #Optional / Default is empty
      disable                       => "true" | "false",               #Optional / Default is "false"
      enable_ddns                   => "true" | "false",               #Optional / Default is "false"
      extattrs                      => { $string => $extattr, ... },      #Optional / Default is
undefined
      extensible_attributes         => { $string => $string | $num, $string => [ $string | $num, ... ],
... }, #Optional / Default is undefined
      force_roaming_hostname        => "true" | "false",               #Optional / Default is "false"
      ignore_dhcp_option_list_request => "true" | "false" | undef,     #Optional / Default is "false"
      ipv6_ddns_domainname          => $string,                        #Optional / Default is undefined
      ipv6_ddns_hostname            => $string,                        #Optional / Default is empty
      ipv6_domain_name_servers      => $string,                        #Optional / Default is undefined
      ipv6_domain_name              => $string,                        #Optional / Default is undefined
      ipv6_duid                     => $duid,                          #Optional / Default is undefined
      ipv6_enable_ddns              => "true" | "false" | undef,       #Optional / Default is undefined
      ipv6_force_roaming_hostname   => "true" | "false",               #Optional / Default is "false"
      ipv6_match_option             => "duid" | undef,                 #Optional / Default is undefined
      ipv6_options                  => [$option1, $option2,...],       #Optional / Default is undefined
      ipv6_template                 => $string,                        #Optional / Default is undefined
      last_discovered               => $string,                        #Optional / Default is empty
      mac                           => $mac_addr,                      #Optional / Default is empty
      match_client                  => "MAC" | "CLIENT_IDENTIFIER",    #Optional / Default is "MAC"
      network_view                  => $NetworkView,                   #Optional / Default is "default"
network view
      nextserver                    => $ipv4addr,                      #Optional / Default is empty
      options                       => [$option1, $option2, ...],      #Optional / Default is undefined
      override_ddns_domainname      => "true" | "false",               #Optional / Default value is "false"
      override_ipv6_ddns_domainname   => "true" | "false",             #Optional / Default is "false"
      override_ipv6_domain_name_servers => "true" | "false",           #Optional / Default is "false"
      override_ipv6_domain_name     => "true" | "false",               #Optional / Default is "false"
      override_ipv6_enable_ddns     => "true" | "false",               #Optional / Default is "false"
      override_ipv6_options         => "true" | "false",               #Optional / Default is "false"
      override_preferred_lifetime   => "true" | "false",               #Optional / Default is "false"
      override_valid_lifetime       => "true" | "false",               #Optional / Default is "false"
      preferred_lifetime            => $num,                           #Optional / Default is 27000
      pxe_lease_time                => $time,                          #Optional / Default is empty
      template                      => $string,                        #Optional / Default is undefined
      valid_lifetime                => $num,                           #Optional / Default is 43200
);
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DHCP Roaming Host object.

Infoblox::Session->add( )

Use this method to add a DHCP Roaming Host object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct a DHCP Roaming Host object
my $roaming_host = Infoblox::DHCP::RoamingHost->new(
        "name"                          => "JohnSmith",
        "bootfile"                      => "bootfile",
        "bootserver"                    => "bootserver.com",
        "client_identifier_prepend_zero"    => "true",
        "comment"                       => "add roaming host using uid",
        "ddns_domainname"               => "ddns.domain.com",
        "ddns_hostname"                 => "ddns.host.domain.com",
        "deny_bootp"                    => "false",
        "dhcp_client_identifier"        => "foo",
        "disable"                       => "false",
        "enable_ddns"                   => "false",
        "match_client"                  => "MAC",
        "network_view"                  => $nview,
        "nextserver"                    => "3.3.3.3",
        "options"                       => [ $option1,  $option2, $option3,  $option4, $option5,
$option6 ],
        "pxe_lease_time"                => "3600",
);

#Submit for addition
my $response = $session->add($roaming_host)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

Apply the following attributes to get a specific DHCP Roaming Host object:

```
  name                    - Optional. The roaming host name.
  mac                     - Optional. MAC address of the roaming host.
  dhcp_client_identifier  - Optional, DHCP option 61 client identifier.
  network_view            - Optional. Network view in which the roaming host is located. By default,
all network views are searched.
  extattrs                - Optional. A hash reference containing extensible attributes.
  extensible_attributes   - Optional. A hash reference containing extensible attributes.
```

Examples

```
#Get DHCP Roaming Host object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::RoamingHost",
    mac    => "11:11:11:11:11.11",
);
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::RoamingHost",
    dhcp_client_identifier => "foo",
);
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::RoamingHost",
    name     => "JohnSmith",
    network_view => "default",
);

my @retrieved_objs = $session->get(
   object               => "Infoblox::DHCP::RoamingHost",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify a DHCP Roaming Host object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the pxe_lease_time
$roaming_host->pxe_lease_time("1234");
#Submit modification
my $response = $session->modify( $roaming_host );
```

Infoblox::Session->remove( )

Use this method to remove a DHCP Roaming Host object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific DHCP Roaming Host, and then submit this object for removal.

Example

```
#Get DHCP Roaming Host object through the session
my @retrieved_objs = $session->get(
    object       => "Infoblox::DHCP::RoamingHost",
    mac          => "11:11:11:11:11:11",
    network_view => "default"
);
#Find the desired object from the retrieved list.
my $desired_roaming_host = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_roaming_host );
```

Infoblox::Session->search( )

Use this method to search for DHCP Roaming Host object and matching Host object with MAC address in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

Apply the following attributes to search for a specific DHCP Roaming Host object:

```
  name           - Optional. The roaming host name (regular expression).
  mac            - Optional. MAC address of the roaming host (regular expression).
  network_view   - Optional. Network view in which the roaming host is located. By default, all
network views are searched.
  extattrs       - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
 # Search for all DHCP Roaming Host objects that are specified in the network "10.0.0.0/8" in the
"default" network view.
 my @retrieved_objs = $session->search(
     object       => "Infoblox::DHCP::RoamingHost",
     mac          => "11:11:11:11:11.*",
     network_view => "default"
 );

 # Search for all DHCP Roaming Host objects with "Santa Clara" for the "Site" extensible attribute
 my @retrieved_objs = $session->search(
     object               => "Infoblox::DHCP::RoamingHost",
     extensible_attributes => { 'Site' => 'Santa Clara' }
 );
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DHCP Roaming Host object.

address_type( )

Use this method to set or retrieve the address_type field.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The possible values for address_type are the following: ipv4 - Roaming hosts are set up for IPv4 addresses only. ipv6 - Roaming hosts are set up for IPv6 addresses only. both - Both types of addresses are set up.

The default value of the parameter is "ipv4".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address_type
my $address_type = $roaminghost->address_type();
#Modify address_type
$roaminghost->address_type("both");
```

bootfile( )

Use this method to set or retrieve the bootfile value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the file the client must download.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootfile
my $bootfile = $roaming_host->bootfile();
#Modify bootfile
$roaming_host->bootfile("boot_file");
```

bootserver( )

Use this method to set or retrieve the bootserver of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the server on which the boot file is stored.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get bootserver
my $bootserver = $roaming_host->bootserver();
#Modify bootserver
$roaming_host->bootserver("bootserver2.com");
```

client_identifier_prepend_zero( )

Use this method to prepend "\000" to the dhcp-client-identifier of a roaming host.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

When you set the client_identifier_prepend_zero parameter to "true", it prefixes a 0 (zero) to the DHCP client identifier whenever option 61 is used to assign roaming hosts. The following is an excerpt from "man dhcp-options":

Please be aware that some DHCP clients, when configured with client identifiers that are ASCII text, will prepend a zero to the ASCII text. So you may need to write: option dhcp-client-identifier "\000foo"; rather than: option dhcp-client-identifier "foo";

Returns

If you specified a parameter, the method returns true when the modification succeeds and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get client_identifier_prepend_zero
my $client_identifier_prepend_zero = $roaming_host->client_identifier_prepend_zero();
#Modify dhcp_client_identifier
$roaming_host->client_identifier_prepend_zero("true");
```

comment( )

Use this method to set or retrieve the descriptive comment of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $roaming_host->comment();
#Modify comment
$roaming_host->comment("Modified DHCP Roaming Host object comment");
```

ddns_domainname( )

Use this method to set or retrieve the DDNS domain name value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_domainname attribute to "false".

Note that when ddns_domainname is set to a defined value and override_dddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_domainname("testdomain"); $object->override_ddns_domainname("false"); will set override_ddns_domainname to "false", and the sequence $object->override_ddns_domainname("false"); $object->ddns_domainname("testdomain"); will result in override_ddns_domainname="true".

Parameter

Specify the DDNS domain name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the DDNS domain name
my $ddns_domainname = $roaming_host->ddns_domainname();
#Modify the DDNS domain name
$roaming_host->ddns_domainname("ddns.domain.com");
```

ddns_hostname( )

Use this method to set or retrieve the DDNS host name value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the DDNS host name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the DDNS host name
my $ddns_hostname = $roaming_host->ddns_hostname();
#Modify the DDNS host name
$roaming_host->ddns_hostname("host.ddns.domain.com");
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $roaming_host->deny_bootp();
#Modify deny_bootp
$roaming_host->deny_bootp("true");
```

dhcp_client_identifier( )

Use this method to set or retrieve the dhcp-client-identifier value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Use the dhcp_client_identifier or uid to assign roaming hosts if the DHCP clients send option 61. A DHCP client identifier can be a string or a MAC address. Set the "match_client" field to "CLIENT_IDENTIFIER" for roaming hosts to use the dhcp_client_identifier instead of the mac_address.

Returns

If you specified a parameter, the method returns true when the modification succeeds and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get dhcp_client_identifier
my $uid = $roaming_host->dhcp_client_identifier();
#Modify dhcp_client_identifier
$roaming_host->dhcp_client_identifier("foo");
or
$roaming_host->dhcp_client_identifier("1:11::11::11::11::11::12");
```

disable( )

Use this method to set or retrieve the disable flag of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $roaming_host->disable();
#Modify disable
$roaming_host->disable("true");
```

discovered_name( )

Use this method to retrieve the discovered name of a DHCP Roaming Host object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
my $discovered_name = $roaming_host->discovered_name();
```

discoverer( )

Use this method to retrieve the discoverer of a DHCP Roaming Host object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $roaming_host->discoverer();
```

enable_ddns( )

Use this method to set or retrieve the enable_ddns flag of a DHCP Roaming Host object.

If enable_ddns value is specified as "true", then the A and PTR records corresponding to the Roaming Host object will be placed on the DNS server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the enable_ddns flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get enable_ddns
my $enable_ddns = $roaming_host->enable_ddns();
#Modify enable_ddns
$roaming_host->enable_ddns("true");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Roaming Host object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
```

```
my $ref_extattrs = $roaming_host->extattrs();
#Modify extattrs
$roaming_host->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP Roaming Host object

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $roaming_host->extensible_attributes();
#Modify extensible attributes
$roaming_host->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom'
] });
```

first_discovered( )

Use this method to retrieve the date and time that the DHCP Roaming Host object was first discovered.

Parameter

none

Returns

The method returns the date and time that the DHCP Roaming Host object was first discovered.

Example

```
#Get first_discovered
my $first_discovered = $roaming_host->first_discovered();
```

force_roaming_hostname( )

Use this method to set or retrieve the force_roaming_hostname flag of a DHCP Roaming Host object.

If the force_roaming_hostname value is "true", then the roaming host name is used as the ddns_hostname.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the force_roaming_hostname flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get force_roaming_hostname
my $force_roaming_hostname = $roaming_host->force_roaming_hostname();
#Modify force_roaming_hostname
$roaming_host->force_roaming_hostname("true");
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a DHCP roaming host object. If this flag is set to false all the defined DHCP options will be returned to the client.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate/unset it. The default value is false which indicates that this attribute inherit the member level setting..

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $roaming_host->ignore_dhcp_option_list_request();
# Un-override ignore_dhcp_option_list_request
$roaming_host->ignore_dhcp_option_list_request(undef);
# Modify ignore_dhcp_option_list_request
$roaming_host->ignore_dhcp_option_list_request("true");
```

ipv6_client_hostname( )

Use this method to retrieve the ipv6_client_hostname of a DHCP Roaming Host object. This method specifies the host name that the DHCP client sends to the Infoblox appliance using DHCP option 12. The method is read-only.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get ipv6_client_hostname
my $ipv6_client_hostname = $roaming_host->ipv6_client_hostname();
```

ipv6_ddns_domainname( )

Use this method to set or retrieve the IPv6 DDNS domain name value for the roaming host.

Setting this method to a defined value implicitly sets the override_ipv6_ddns_domainname method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_ipv6_ddns_domainname attribute to "false".

Note that when ipv6_ddns_domainname is set to a defined value and override_ipv6_ddns_domainname is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_ddns_domainname("testdomain"); $object->override_ipv6_ddns_domainname("false"); will set override_ipv6_ddns_domainname to "false", and the sequence $object->override_ipv6_ddns_domainname("false"); $object->ipv6_ddns_domainname("testdomain"); will result in override_ipv6_ddns_domainname="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The DDNS domain name in FQDN (Fully Qualified Domain Name) format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_ddns_domainname
my $ipv6_ddns_domainname = $roaming_host->ipv6_ddns_domainname();
#Modify ipv6_ddns_domainname
$roaming_host->ipv6_ddns_domainname("domain.com");
```

ipv6_ddns_hostname( )

Use this method to set or retrieve the IPv6 DDNS host name value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify the IPv6 DDNS host name.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get the IPv6 DDNS host name
my $ipv6_ddns_hostname = $roaming_host->ipv6_ddns_hostname();
#Modify the IPv6 DDNS host name
$roaming_host->ipv6_ddns_hostname("host.ddns.domain.com");
```

ipv6_domain_name( )

Use this method to set or retrieve the ipv6_domain_name value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_domain_name method to "true". Setting the parameter to undefined causes the appliance to use the upper level default and automatically resets the override_ipv6_domain_name attribute to "false".

Note that when ipv6_domain_name is set to a defined value and override_ipv6_domain_name is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_domain_name("testdomain"); $object->override_ipv6_domain_name("false"); will set override_ipv6_domain_name to "false", and the sequence $object->override_ipv6_domain_name("false"); $object->ipv6_domain_name("testdomain"); will result in override_ipv6_domain_name="true".

Parameter

The name, in string format, of the client's domain for resolving names in DNS.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_domain_name
my $ipv6_domain_name = $roaming_host->ipv6_domain_name();
#Modify ipv6_domain_name
$roaming_host->ipv6_domain_name("test_domain.com");
```

ipv6_domain_name_servers( )

Use this method to set or retrieve the ipv6_domain_name_servers value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ipv6_domain_name_servers method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_ipv6_domain_name_servers attribute to "false".

Note that when ipv6_domain_name_servers is set to a defined value and override_ipv6_domain_name_servers is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_domain_name_servers("2001::1,2001::2"); $object->override_ipv6_domain_name_servers("false"); will set override_ipv6_domain_name_servers to "false", and the sequence $object->override_ipv6_domain_name_servers("false"); $object->ipv6_domain_name_servers("2001::1,2001::2"); will result in override_ipv6_domain_name_servers="true".

Parameter

The IPv6 addresses of the DNS servers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_domain_name_servers
my $ipv6_domain_name_servers = $roaming_host->ipv6_domain_name_servers();
#Modify ipv6_domain_name_servers
$roaming_host->ipv6_domain_name_servers("2001::1,2001::2");
```

ipv6_duid( )

Use this method to set or retrieve the DHCPv6 Unique Identifier (DUID) of the Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The DUID of the matching client in hexadecimal format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_duid
my $ipv6_duid = $roaming_host->ipv6_duid();
#Modify ipv6_duid
$roaming_host->ipv6_duid("1c2edfaa");
```

ipv6_enable_ddns( )

Use this method to set or retrieve the ipv6_enable_ddns flag for the roaming host. Set this flag to enable DHCPv6 dynamic DNS updates.

Setting this method to a defined value implicitly sets the override_ipv6_enable_ddns method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_ipv6_enable_ddns attribute to "false".

Note that when ipv6_enable_ddns is set to a defined value and override_ipv6_enable_ddns is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_enable_ddns("false"); $object->override_ipv6_enable_ddns("false"); will set override_ipv6_enable_ddns to "false", and the sequence $object->override_ipv6_enable_ddns("false"); $object->ipv6_enable_ddns("false"); will result in override_ipv6_enable_ddns="true".

Parameter

Specify "true" to enable this feature or "false" to disable it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_enable_ddns
my $ipv6_enable_ddns = $roaming_host->ipv6_enable_ddns();
#Modify ipv6_enable_ddns
$roaming_host->ipv6_enable_ddns("true");
```

ipv6_force_roaming_hostname( )

Use this method to set or retrieve the ipv6_force_roaming_hostname flag of a DHCP Roaming Host object.

If the ipv6_force_roaming_hostname value is "true", then the roaming host name is used as the ddns_hostname. This flag applies to IPv6 roaming hosts.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ipv6_force_roaming_hostname flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_force_roaming_hostname
my $ipv6_force_roaming_hostname = $roaming_host->ipv6_force_roaming_hostname();
#Modify ipv6_force_roaming_hostname
$roaming_host->ipv6_force_roaming_hostname("true");
```

ipv6_match_option( )

Use this method to set or retrieve the ipv6_match_option value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

This field specifies the identification method for an IPv6 or mixed IPv4/IPv6 roaming host. Currently, the only supported value for this field is "duid", which corresponds to identification by DHCPv6 unique ID. The default value of this parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_match_option
my $ipv6_match_option = $roaming_host->ipv6_match_option();
#Modify ipv6_match_option
$roaming_host->ipv6_match_option("duid");
```

ipv6_options( )

Use this method to set or retrieve the IPv6 options of a DHCP Roaming Host object.

Setting this method to a defined value implicitly sets the override_ipv6_options method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_ipv6_options attribute to "false".

Note that when ipv6_options is set to a defined value and override_ipv6_options is set to "false", the last operation takes precedence. Thus the sequence $object->ipv6_options([$option1]); $object->override_ipv6_options("false"); will set override_ipv6_options to "false", and the sequence $object->override_ipv6_options("false"); $object->ipv6_options([$option1]); will result in override_ipv6_options="true".

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_options
my $ipv6_options = $roaming_host->ipv6_options();
#Modify ipv6_options
my $option1 = Infoblox::DHCP::Option->new(
    name   => "dhcp6.info-refresh-time",
    value  => "1000"
);
$roaming_host->ipv6_options([$option1]);
```

ipv6_template( )

Use this method to set or retrieve the fixed address ipv6_template name for a DHCP Roaming Host object.

Specify the IPv6 fixed address template that is used to create the DHCP roaming host.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The IPv6 fixed address template name in sting format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

The ipv6_template parameter can be used only to add a new DHCP roaming host. It cannot be used to modify an object or return an object during a get operation.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6_template
my $ipv6_template = $roaming_host->ipv6_template();
#Modify ipv6_template
$roaming_host->ipv6_template("Template_Name");
```

last_discovered( )

Use this method to retrieve the time this object was last seen by a discovery job.

The default value for this field is empty.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get last_discovered
my $last_discovered = $roaming_host->last_discovered();
```

mac( )

Use this method to set or retrieve the MAC address value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

MAC Address of the DHCP roaming host object. Format for the hexadecimal strings for MAC addresses and vendor prefixes with colons or dashes. Both of the following formats are acceptable: 11:11:11:11:11:11 and 11-11-11-11-11-11.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mac
my $mac = $roaming_host->mac();
#Modify mac
$roaming_host->mac("11::11::11::11::11::12");
```

match_client( )

Use this method to set or retrieve the match_client value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

match_client "MAC": The fixed IP address is leased to the matching MAC address.
match_client "CLIENT_IDENTIFIER": The fixed IP address is leased to the matching DHCP client identifier
Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get match_client
my $match_client = $roaming_host->match_client();
#Modify match_client
$roaming_host->match_client("CLIENT_IDENTIFIER");
```

name( )

Use this method to set or retrieve the roaming host name associated with the DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

NOTE: To enable using roaming hosts, you must allow roaming hosts at the grid level by setting $griddhcp->enable_roaming_hosts("true");

Parameter

Desired roaming host name in string format with a maximum of 64 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get roaming host name
my $roaming_host_name = $roaming_host->name();
#Modify roaming host name
$roaming_host->name("JimmyJaz");
```

netbios( )

Use this method to retrieve the name in the NetBIOS reply that responded to a NetBIOS query.

Returns

The method returns the attribute value.

Example

```
#Get netbios
my $netbios = $roaming_host->netbios();
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $roaming_host->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the IP address of the network device.

Example

```
#Get network_component_ip
my $network_component_ip = $roaming_host->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the network device name.

Example

```
#Get network_component_name
my $network_component_name = $roaming_host->network_component_name();
```

network_component_port_description( )

Use this method to retrieve the description of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the description of the port on the network device.

Example

```
#Get network_component_port_description
my $network_component_port_description = $roaming_host->network_component_port_description();
```

network_component_port_name( )

Use this method to retrieve the name of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the name of the port on the network device.

Example

```
#Get network_component_port_name
my $network_component_port_name = $roaming_host->network_component_port_name();
```

network_component_port_number( )

Use this method to retrieve the number of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the network device port number.

Example

```
#Get network_component_port_number
my $network_component_port_number = $roaming_host->network_component_port_number();
```

network_component_type( )

Use this method to retrieve the type of the network device that is connected to DHCP Roaming Host object.

Parameter

none

Returns

The method returns the network device type.

Example

```
#Get network_component_type
my $network_component_type = $roaming_host->network_component_type();
```

network_view( )

Use this method to set or retrieve the network view of the DHCP roaming host

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the roaming host is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $roaming_host->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$roaming_host->network_view($nview);
```

nextserver( )

Use this method to set or retrieve the nextserver value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IP address of the boot file server on which the boot file is stored.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get nextserver
my $nextserver = $roaming_host->nextserver();
#Modify nextserver
$roaming_host->nextserver("3.3.3.4");
```

options( )

Use this method to set or retrieve the options of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

See Infoblox::DHCP::Option for parameters and methods available for this object.

Parameter

Options describe network configuration settings and various services available on the network. These options occur as variable-length fields at the end of DHCP messages.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $roaming_host->options();
#Modify options
$roaming_host->options([$option1, $option2]);
```

os( )

Use this method to retrieve the operating system associated with this roaming host.

Returns

The method returns the attribute value.

Example

```
#Get os
my $os = $roaming_host->os();
```

override_ddns_domainname( )

The override_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP Roaming Host is used, instead of the grid default.

The override_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_domainname. Set the parameter to "false" to inherit the grid-level setting for ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_domainname
my $override_ddns_domainname=$roaming_host->override_ddns_domainname( );
#Modifying override_ddns_domainname
$roaming_host->override_ddns_domainname("true");
```

override_ipv6_ddns_domainname( )

The override_ipv6_ddns_domainname attribute controls whether the ddns_domainname value in the DHCP Roaming Host object is used, instead of the upper-level default.

The override_ipv6_ddns_domainname attribute can be specified explicitly. It is also set implicitly when ipv6_ddns_domainname is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ddns_domainname. Set the parameter to "false" to inherit the upper-level setting for ipv6_ddns_domainname.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_ddns_domainname
my $override_ipv6_ddns_domainname=$roaming_host->override_ipv6_ddns_domainname( );
#Modifying override_ipv6_ddns_domainname
$roaming_host->override_ipv6_ddns_domainname("true");
```

override_ipv6_domain_name( )

Use this method to set or retrieve the override_ipv6_domain_name value of a DHCP Roaming Host object.

The override_ipv6_domain_name attribute can be specified explicitly. It is also set implicitly when ipv6_domain_name is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipv6_domain_name. Set the parameter to "false" to inherit the upper-level setting for ipv6_domain_name.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ipv6_domain_name
my $override_ipv6_domain_name = $roaming_host->override_ipv6_domain_name();
#Modify override_ipv6_domain_name
$roaming_host->override_ipv6_domain_name("test_domain.com");
```

override_ipv6_domain_name_servers( )

Use this method to set or retrieve the override_ipv6_domain_name_servers value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipv6_domain_name_servers. Set the parameter to "false" to inherit the upper-level setting for ipv6_domain_name_servers.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_ipv6_domain_name_servers
my $override_ipv6_domain_name_servers = $roaming_host->override_ipv6_domain_name_servers();
#Modify override_ipv6_domain_name_servers
$roaming_host->override_ipv6_domain_name_servers("true");
```

override_ipv6_enable_ddns( )

The override_ipv6_enable_ddns attribute controls whether the ipv6_enable_ddns value in the DHCP Roaming Host object is used, instead of the upper-level default.

The override_ipv6_enable_ddns attribute can be specified explicitly. It is also set implicitly when ipv6_enable_ddns is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipv6_enable_ddns. Set the parameter to "false" to inherit the upper-level setting for ipv6_enable_ddns.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_enable_ddns
my $override_ipv6_enable_ddns=$roaming_host->override_ipv6_enable_ddns( );
#Modifying override_ipv6_enable_ddns
$roaming_host->override_ipv6_enable_ddns("true");
```

override_ipv6_options( )

The override_ipv6_options attribute controls whether the ipv6_options value in the DHCP Roaming Host object is used, instead of the upper-level default.

The override_ipv6_options attribute can be specified explicitly. It is also set implicitly when ipv6_options is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ipv6_options. Set the parameter to "false" to inherit the upper-level setting for ipv6_options.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ipv6_options
my $override_ipv6_options=$roaming_host->override_ipv6_options( );
#Modifying override_ipv6_options
$roaming_host->override_ipv6_options("true");
```

override_preferred_lifetime( )

The override_preferred_lifetime attribute controls whether the preferred_lifetime value in the DHCP Roaming Host object is used, instead of the upper-level default.

The override_preferred_lifetime attribute can be specified explicitly. It is also set implicitly when preferred_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for preferred_lifetime. Set the parameter to "false" to inherit the upper-level setting for preferred_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_preferred_lifetime
my $override_preferred_lifetime=$roaming_host->override_preferred_lifetime( );
#Modifying override_preferred_lifetime
$roaming_host->override_preferred_lifetime("true");
```

override_valid_lifetime( )

The override_valid_lifetime attribute controls whether the valid_lifetime value in the DHCP Roaming Host object is used, instead of the upper-level default.

The override_valid_lifetime attribute can be specified explicitly. It is also set implicitly when valid_lifetime is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for valid_lifetime. Set the parameter to "false" to inherit the upper-level setting for valid_lifetime.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_valid_lifetime
my $override_valid_lifetime=$roaming_host->override_valid_lifetime( );
#Modifying override_valid_lifetime
```

```
$roaming_host->override_valid_lifetime("true");
```

port_duplex( )

Use this method to retrieve the duplex setting of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the port duplex setting. Returned values, if any, are one of the following:

Full
Half
Example

```
#Get port_duplex
my $port_duplex = $roaming_host->port_duplex();
```

port_link_status( )

Use this method to retrieve the link status of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the network device port link status. Returned values, if any, are one of the following: Connected Not Connected Unknown

Example

```
#Get port_link_status
my $port_link_status = $roaming_host->port_link_status();
```

port_speed( )

Use this method to retrieve the speed of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the network device port speed. Returned values, if any, are one of the following:

10 M
100 M
1G
10G
100G
Unknown
Example

```
#Get port_speed
my $port_speed = $roaming_host->port_speed();
```

port_status( )

Use this method to retrieve the status of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the network device port status. Returned values, if any, are one of the following:

Up
Down
Unknown

Example

```
#Get port_status
my $port_status = $roaming_host->port_status();
```

port_vlan_description( )

Use this method to retrieve the VLAN description of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the VLAN description of the network device port.

Example

```
#Get port_vlan_description
my $port_vlan_description = $roaming_host->port_vlan_description();
```

port_vlan_name( )

Use this method to retrieve the VLAN name of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the network device port VLAN name.

Example

```
#Get port_vlan_name
my $port_vlan_name = $roaming_host->port_vlan_name();
```

port_vlan_number( )

Use this method to retrieve the VLAN number of the network device port that is connected to the DHCP Roaming Host object.

Parameter

none

Returns

The method returns the port VLAN number.

Example

```
#Get port_vlan_number
my $port_vlan_number = $roaming_host->port_vlan_number();
```

preferred_lifetime( )

Use this method to set or retrieve the preferred lifetime of the roaming host.

Setting this method to a defined value implicitly sets the override_preferred_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_preferred_lifetime attribute to "false".

Note that when preferred_lifetime is set to a defined value and override_preferred_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->preferred_lifetime(20000); $object->override_preferred_lifetime("false"); will set override_preferred_lifetime to "false", and the sequence $object->override_preferred_lifetime("false"); $object->preferred_lifetime(20000); will result in override_preferred_lifetime="true".

Parameter

Preferred lifetime value in seconds. The default value is 27000. Note that the preferred lifetime cannot be greater than the valid lifetime.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get preferred_lifetime
my $preferred_lifetime = $roaming_host->preferred_lifetime();
#Modify preferred_lifetime
$roaming_host->preferred_lifetime(12345);
```

pxe_lease_time( )

Use this method to set or retrieve the pxe_lease_time value of a DHCP Roaming Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter appropriate values in the Days, Hours, Mins and Secs fields. Users can specify the duration of time it takes a host to connect to a boot server, such as a TFTP server, and download the file it needs to boot.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get pxe_lease_time
my $pxe_lease_time = $roaming_host->pxe_lease_time();
#Modify pxe_lease_time
$roaming_host->pxe_lease_time("369");
```

template( )

Use this method to set the fixed address template name for a DHCP Roaming Host object.

Template is the name of a DHCP Fixed Address template which will be used to create the DHCP Roaming Host.

Parameter

The valid name in string format.

Returns

The method returns true when the modification succeeds, and returns false when the operation fails.

The template parameter can be used to only add a new DHCP Roaming Host and cannot be used during object modify or returned during object get.

Example

```
#Add RoamingHost with template
my $roaming_host = Infoblox::DHCP::RoamingHost->new(
        "name"   => "JohnSmith",
        "template"   => "Template_Name",
);
#Submit for addition
my $response = $session->add($roaming_host)
```

valid_lifetime( )

Use this method to set or retrieve the preferred lifetime of the roaming host.

Setting this method to a defined value implicitly sets the override_valid_lifetime method to "true". Setting the parameter to undefined causes the appliance to use the upper-level default and automatically resets the override_valid_lifetime attribute to "false".

Note that when valid_lifetime is set to a defined value and override_valid_lifetime is set to "false", the last operation takes precedence. Thus the sequence $object->valid_lifetime(20000); $object->override_valid_lifetime("false"); will set override_valid_lifetime to "false", and the sequence $object->override_valid_lifetime("false"); $object->valid_lifetime(20000); will result in override_valid_lifetime="true".

Parameter

Valid lifetime value in seconds. The default value is 43200.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get valid_lifetime
my $valid_lifetime = $roaming_host->valid_lifetime();
#Modify valid_lifetime
$roaming_host->valid_lifetime(12345);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

```
#Preparation prior to a DHCP Fixed Address object insertion

#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Modify Grid DHCP object to enable support of the Roaming Hosts

```
my $grid_dhcp=$session->get(
                            object => "Infoblox::Grid::DHCP",
                            name=>"Infoblox"
                            );
unless ($grid_dhcp) {
    die("Get Grid DHCP object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Grid DHCP object found at least 1 matching entry\n";

my $save_grid_rh_status=$grid_dhcp->enable_roaming_hosts();
$grid_dhcp->enable_roaming_hosts("true");
unless($session->modify($grid_dhcp)) {
    die("Modifying Grid DHCP object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Roaming Hosts enabled at Grid level successfuly\n";

#Adding DHCP options
my $option1 = Infoblox::DHCP::Option->new(
                                          "name"  => "lease-time",
                                          "value" => "50"
                                         );

unless($option1) {
     die("Construct option1 object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "option1 object created successfully\n";

my $option2 = Infoblox::DHCP::Option->new(
                                          "type"      => "routers",
                                          "ipv4addrs" => ["10.0.0.1","10.0.0.255"],
                                         );

unless($option2) {
     die("Construct option2 object failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "option2 object created successfully\n";
```

#Create a DHCP Roaming Host object

```
#Create a DHCP Roaming Host object
my $roaming_host = Infoblox::DHCP::RoamingHost->new(
        "name"        => "JohnSmith",
        "mac"             => "00:00:00:11:11:11",
        "comment"         => "add roaming host",
        "enable_ddns"     => "true",
        "pxe_lease_time" => "3600",
        "bootserver"      => "someserver.com",
        "nextserver"      => "3.3.3.3",
        "bootfile"        => "bootfile.com",
        "options"         => [ $option1 , $option2 ],
        );
unless($roaming_host) {
     die("Construct roaming host failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Roaming Host object created successfully\n";

#Verify if the DHCP Roaming Host exists in the Infoblox appliance
my $object = $session->get(object => "Infoblox::DHCP::RoamingHost", mac => "00:00:00:11:11:11");
unless ($object) {
   print "roaming host does not exist on server, safe to add the roaming host\n";
   $session->add($roaming_host)
      or die("Add roaming host failed: ",
             $session->status_code() . ":" . $session->status_detail());
}
print "DHCP Roaming Host added successfully\n";
```

#Search for a specific DHCP Roaming Host object

```
#Search for all DHCP Roaming Host objects with a given mac address
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::RoamingHost",
    mac     => "00:00:00:11:11.*",
     );
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search for Roaming Host object failed: ",
              $session->status_code() . ":" . $session->status_detail());
}
print "Search Roaming Host object found at least 1 matching entry\n";
```

#Get and modify a DHCP Roaming Host object

```
#Get DHCP Roaming Host object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::RoamingHost",
    mac    => "00:00:00:11:11:11",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get Roaming Host object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Roaming Host object found at least 1 matching entry\n";

#Modify one of the attributes of the obtained Roaming Host object
$object->pxe_lease_time("1234");

#Apply the changes
$session->modify($object)
    or die("Modify Roaming Host object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Roaming Host object modified successfully \n";
```

#Remove a Roaming Host object

```
#Get Roaming Host object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DHCP::RoamingHost",
    mac    => "00:00:00:11:11:11",
);
my $object = $retrieved_objs[0];
unless ($object) {
```

```
    die("Get Roaming Host object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Roaming Host object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove Roaming Host object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "Roaming Host object removed successfully \n";

#Restore Grid DHCP
$grid_dhcp->enable_roaming_hosts($save_grid_rh_status);
print "Grid DHCP setting restored successfully\n" if($session->modify($grid_dhcp));

NAME

Infoblox::DHCP::SharedNetwork - DHCP Shared Network object

DESCRIPTION

You can create a shared network when two subnets share a particular network segment. Before creating a shared network, you must first create the subnetworks. For example, you must first create the networks 10.32.1.0 and 10.30.0.0 before designating them as a shared network.

CONSTRUCTOR

```
  my $sharednetwork = Infoblox::DHCP::SharedNetwork->new(
                  name                              => $string,                          #Required
                  networks                          => [ $Network1,$Network2,...],       #Required
                  authority                         => "true" | "false" | undef,         #Optional / Default
is undefined
                  bootfile                          => $filename | undef,                #Optional / Default
is undefined
                  bootserver                        => $ipv4addr | $fqdn | undef,
#Optional / Default is undefined
                                                       $string   undef                   #Optional / Default
```

```
                comment                          =>         |      ,
is undefined
                ddns_generate_hostname           => "true" | "false" | undef,          #Optional / Default
is undefined
                ddns_server_always_updates       => "true" | "false",                  #Optional / Default
is "true"
                ddns_update_fixed_addresses      => "true" | "false" | undef,          #Optional / Default
is undefined
                ddns_ttl                         => $num,                              #Optional / Default
is zero
                ddns_use_option81                => "true" | "false" | undef,          #Optional / Default
is undefined
                deny_bootp                       => "true" | "false" | undef,          #Optional / Default
is undefined
                disable                          => "true" | "false",                  #Optional / Default
is "false"
                enable_ddns                      => "true" | "false" | undef,          #Optional / Default
is undefined
                extattrs                         => { $string => $extattr, ... },      #Optional / Default
is undefined
                extensible_attributes            => { $string => $string | $num, $string => [ $string |
$num, ... ], ... }, #Optional / Default is undefined
                ignore_dhcp_option_list_request  => "true" | "false" | undef,          #Optional / Default
is "false"
                ignore_id                        => 'NONE' | 'CLIENT' | 'MACADDR',     #Optional / Default
is 'NONE'
                ignore_mac_addresses             => [ "mac_addr", ... ] | undef        #Optional / Default
is undefined
                lease_scavenge_time              => $number,                           #Optional / Default
is -1
                network_view                     => $NetworkView,                      #Optional / Default
is "default" network view
                nextserver                       => $ipv4addr | $fqdn | undef,
#Optional / Default is undefined
                options                          => [$Option1,$Option2,...],           #Optional / Default
is empty list
                override_ddns_ttl                => "true" | "false",                  #Optional / Default
value is "false"
                override_lease_scavenge_time     => "true" | "false",                  #Optional / Default
value is "false"
                override_update_dns_on_lease_renewal  => "true" | "false",             #Optional / Default
value is "false"
                override_ignore_id               => "true" | "false",                  #Optional / Default
value is "false"
                pxe_lease_time                   => $num | undef,                      #Optional / Default
is undefined
                update_dns_on_lease_renewal      => "true" | "false",                  #Optional / Default
value is "false"
                logic_filters                    => [ $filter_name | $filter_obj, ...], # Optional /
Default is undefined
                override_logic_filters           => "true' | 'false",                    # Optional /
Default value is "false"
              );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DHCP shared network object.

Infoblox::Session->add( )

Use this method to add a shared network object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object for network
my $network1 = Infoblox::DHCP::Network->new(
        network => "20.0.0.0/8",
);

#Construct an object shared network
  my $sharednetwork = Infoblox::DHCP::SharedNetwork->new(
        name     => "myname",
        networks => [$network1],
);

# Submit for adding sharednetwork
my $response = $session->add( $sharednetwork );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching shared network objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP shared network object:

  name           - Required.    The name of the shared network in string format.
  network        - Optional.    The network with which the shared network associated.
  network_view   - Optional.    The network view in which the shared network is located. By default,
all network views are searched.
  extattrs       - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
my  @result_array = $session->get(
      object       => "Infoblox::DHCP::SharedNetwork" ,
      name         => "myname",
      network_view => "default"
);

my  @result_array = $session->get(
      object       => "Infoblox::DHCP::SharedNetwork" ,
      network      => "1.0.0.0/24",
      network_view => "default"
);
```

Infoblox::Session->modify( )

Use this method to modify a shared network object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify enable_ddns method.
$object->enable_ddns("true");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove a shared network object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Get the object under the same name
my  @result_array = $session->get(
      object       => "Infoblox::DHCP::SharedNetwork" ,
      name         => "myname",
      network_view => "default"
 );

# find the desired object from retrieved list.
my $desired_network = $result_array[0];

# Submit for removal
my $response = $session->remove( $desired_network );
```

Infoblox::Session->search( )

Use this method to search for DHCP shared network object in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a DHCP shared network object:

  name           - Required. The name of the shared network in string format (regular expression).
  network        - Optional. The network with which the shared network associated.
  network_view   - Optional. The network view in which the shared network is located. By default, all
network views are searched.
  extattrs       - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all DHCP shared network objects in the "default" network view
    my @retrieved_objs = $session->search(
      object    => "Infoblox::DHCP::SharedNetwork",
      name      => "my.*",
      network_view => "default"
    );

# search all Shared Networks Templates with a given extensible attribute 'Site'
    my @retrieved_objs = $session->search(
      object => "Infoblox::DHCP::SharedNetwork",
      extensible_attributes => { 'Site' => 'Santa Clara' }
    );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of DHCP a shared network object

authority( )

Use this method to set or retrieve the authority flag of a shared network object. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the authority flag or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute is inherited from the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get authority
my $authority = $sharednetwork->authority()
# Modify authority
$sharednetwork->authority("true");
```

bootfile( )

Use this method to set or retrieve a bootfile attribute of a shared network object. You can configure the DHCP server to support clients that use the boot file name option in their DHCPREQUEST messages. This setting overrides the member-level settings. The default value is undefined, which indicates that this attribute is inherited from the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::SharedNetwork->bootserver() and Infoblox::DHCP::SharedNetwork->nextserver().

Parameter

The name of the file that the client must download. The file name must be in string format and can have a maximum of 128 characters. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get bootfile
my $bootfile = $sharednetwork->bootfile();
# Modify bootfile
$sharednetwork->bootfile("bootfile1");
#Un-override bootfile
$sharednetwork->bootfile(undef);
```

---

bootserver( )

Use this method to set or retrieve the bootserver attribute of a shared network object. You can specify the name and/or IP address of the boot server that the host must access in order to boot. This setting overrides the member-level settings. The default value is undefined, which indicates that this attribute is inherited from the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::SharedNetwork->bootfile() and Infoblox::DHCP::SharedNetwork->nextserver().

Parameter

The boot server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A boot server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get bootserver
my $bootserver = $sharednetwork->bootserver();
# Modify bootserver
$sharednetwork->bootserver("abc.domain.com");
#Un-override bootserver
$sharednetwork->bootserver(undef);
```

comment( )

Use this method to set or retrieve a descriptive comment for a shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $sharednetwork->comment();
# Modify comment
$sharednetwork->comment("add a shared network");
```

ddns_generate_hostname( )

Use this method to set or retrieve the ddns_generate_hostname flag of a shared network object. Enable this method to allow only the DHCP server to generate host name. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to generate the host name or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute is inherited from the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_generate_hostname
my $ddns_generate_hostname = $sharednetwork->ddns_generate_hostname()
# Modify ddns_generate_hostname
$sharednetwork->ddns_generate_hostname("true");
#Un-override
```

```
$sharednetwork->ddns_generate_hostname(undef);
```

ddns_server_always_updates( )

Use this method to set or retrieve the ddns_server_always_updates flag of a shared network object. Enable this method to allow only the DHCP server to update DNS,regardless of the requests from the DHCP clients.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to allow only the DHCP server to update DNS or "false" to deactivate/unset it. The default value for this field is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_server_always_updates
my $ddns_server_always_updates = $sharednetwork->ddns_server_always_updates()
# Modify ddns_server_always_updates
$sharednetwork->ddns_server_always_updates("true");
```

ddns_update_fixed_addresses( )

Use this method to set or retrieve the ddns_update_fixed_addresses flag of a shared network object. By default, the DHCP server does not update DNS when it allocates a fixed address to a client. You can configure the DHCP server to update the A and PTR record of clients with fixed addresses. When you enable this feature and the DHCP server adds A and PTR records for a fixed address, the DHCP server never discards the records. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to update DNS when the device allocates a fixed address to a client or "false" to deactivate/unset it. The default value for this field is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_update_fixed_addresses
my $ddns_update_fixed_addresses= $sharednetwork->ddns_update_fixed_addresses()
# Modify ddns_update_fixed_addresses
$sharednetwork->ddns_update_fixed_addresses("true");
#Un-override
$sharednetwork->ddns_update_fixed_addresses(undef);
```

ddns_ttl( )

Use this method to set or retrieve the DNS update Time to Live (TTL) value of a shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_ddns_ttl method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_ddns_ttl attribute to "false".

Note that when ddns_ttl is set to a defined value and override_dddns_ttl is set to "false", the last operation takes precedence. Thus the sequence $object->ddns_ttl(12); $object->override_ddns_ttl("false"); will set override_ddns_ttl to "false", and the sequence $object->override_ddns_ttl("false"); $object->ddns_ttl(12); will result in override_ddns_ttl="true".

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration,in seconds, that the update is cached. Zero indicates that the update should not be cached. The default value is zero.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get DNS Update ttl
my $dns_ttl = $sharednetwork->ddns_ttl();
#Modify DNS Update ttl
$sharednetwork->ddns_ttl(1200);
```

ddns_use_option81( )

Use this method to set or retrieve the ddns_use_option81 flag of a shared network object. Set this flag to define the settings for option 81 at the network level. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to configure support for option 81 or "false" to deactivate/unset it. The default value for this field is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ddns_use_option81
my $ddns_use_option81 = $sharednetwork->ddns_use_option81()
# Modify ddns_use_option81
$sharednetwork->ddns_use_option81("true");
# un-override ddns_use_option81
$sharednetwork->ddns_use_option81(undef);
```

deny_bootp( )

Use this method to set or retrieve the deny_bootp flag of a DHCP Shared Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the deny_bootp flag or "false" to deactivate/unset it. The default value is undefined, which indicates that this attribute is inherited from the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get deny_bootp
my $deny_bootp = $sharednetwork->deny_bootp();
#Modify deny_bootp
$sharednetwork->deny_bootp("true");
```

disable( )

Use this method to set or retrieve the disable flag of a shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the disable flag and disable the shared network or "false" to unset the flag and enable the shared network. The default value for this field is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get disable
```

```
my $disable = $sharednetwork->disable()
# Modify disable
$sharednetwork->disable("true");
```

enable_ddns( )

Use this method to set or retrieve the dynamic DNS updates flag of a DHCP shared network object. The DHCP server can send DDNS updates to DNS servers in the same grid and to external DNS servers. This setting overrides the member-level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the dynamic DNS updates flag or "false" to deactivate/unset it. The default value for this field is undefined, which indicates that this attribute is inherited from the member-level setting.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get enable_ddns
my $enable_ddns = $sharednetwork->enable_ddns()
# Modify enable_ddns
$sharednetwork->enable_ddns("true");
# Un-override enable_ddns
$sharednetwork->enable_ddns(undef);
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a Shared Network object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $sharednetwork->extattrs();
#Modify extattrs
$sharednetwork->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a Shared Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $shared_network->extensible_attributes();
#Modify extensible attributes
$shared_network->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter',
'Tom' ] });
```

ignore_id( )

Use this method to set or retrieve the ignore_id type of a DHCP shared network object. Indicates whether the appliance will ignore DHCP client IDs or MAC addresses. This setting overrides the upper-level settings.

Parameter

Valid values are 'NONE', 'CLIENT', or 'MACADDR'. The default is 'NONE'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $shared_network->ignore_id();
# Modify attribute value
$shared_network->ignore_id('CLIENT');
#Un-override ignore_id
$shared_network->ignore_id(undef);
```

ignore_mac_addresses( )

Use this method to set or retrieve the ignore_mac_addresses list of a DHCP shared network object. A list of MAC addresses the appliance will ignore. This setting overrides the upper-level settings.

If you enter MAC addresses in the ignore_mac_addresses, then the appliance will ignore them. If you enter empty array, then the appliance will ignore any MAC address.

Parameter

The valid value is an array reference that contains string objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
$value = $shared_network->ignore_mac_addresses();
# Modify attribute value
$shared_network->ignore_mac_addresses(["11::11::11::11::11::11"]);
```

ignore_dhcp_option_list_request( )

Use this method to set or retrieve the ignore_dhcp_option_list_request flag of a DHCP shared network object. If this flag is set to true all the defined DHCP options will be returned to the client. This setting overrides the member level settings.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the ignore_dhcp_option_list_request flag or "false" to deactivate/unset it. The default value is false which indicates that this attribute inherit the member level setting..

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get ignore_dhcp_option_list_request
my $ignore_dhcp_option_list_request = $sharednetwork->ignore_dhcp_option_list_request();
# Un-override ignore_dhcp_option_list_request
$sharednetwork->ignore_dhcp_option_list_request(undef);
# Modify ignore_dhcp_option_list_request
$sharednetwork->ignore_dhcp_option_list_request("true");
```

lease_scavenge_time( )

Use this method to set or retrieve the lease_scavenge_time value of a Shared Network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_lease_scavenge_time method to "true". Setting the parameter to undefined causes the appliance to use the default from the upper level and automatically resets the override_lease_scavenge_time attribute to "false".

Note that when lease_scavenge_time is set to a defined value and override_lease_scavenge_time is set to "false", the last operation takes precedence. Thus the sequence $object->lease_scavenge_time(604800); $object->override_lease_scavenge_time("false"); will set override_lease_scavenge_time to "false", and the sequence $object->override_lease_scavenge_time("false"); $object->lease_scavenge_time(604800); will result in override_lease_scavenge_time="true".

Parameter

An integer that specifies the period of time, in seconds, that free and backup leases remain in the database before they are automatically deleted. To disable lease scavenging, set the parameter to -1. The minimum positive value must be greater than 86400 seconds (1 day). The default value of this parameter is -1, which means that lease scavenging is disabled.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lease_scavenge_time
my $lease_scavenge = $sharednetwork->lease_scavenge_time();
#Modify lease_scavenge_time
$sharednetwork->lease_scavenge_time(30 * 24 * 60 * 60);
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $sharednetwork->ms_ad_user_data();
```

logic_filters( )

Use this method to set or retrieve all the logic (ordered) filters associated with the DHCP Shared Network.

Filters are used to screen address assignments in a DHCP Shared Network if the addresses are to be assigned to specific hosts.

Setting this method to a defined value implicitly sets the override_logic_filters method to "true". Setting the parameter to undefined causes the appliance to use the Grid default and automatically resets the override_logic_filters attribute to "false".

Note that when logic_filters is set to a defined value and override_dlogic_filters is set to "false", the last operation takes precedence. Thus the sequence $object->logic_filters($filters); $object->override_logic_filters("false"); will set override_logic_filters to "false", and the sequence $object->override_logic_filters("false"); $object->logic_filters($filters); will result in override_logic_filters="true".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains either the Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC, Infoblox::DHCP::Filter::Option objects or the names of the corresponding filters. The filters in the list must satisfy the following conditions:

Filter name must be globally unique.
Filters without expressions must be at the end of the list.
The filters should not be disabled.

The default value of the parameter is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get logic_filters
my $ref_logic_filters = $sharednetwork->logic_filters();
#Modify logic_filters
$sharednetwork->logic_filters(["filter_1","filter_2",$exl1]); #$exl1 is an
Infoblox::DHCP::Filter::MAC, Infoblox::DHCP::Filter::NAC or Infoblox::DHCP::Filter::Option object.
```

name( )

Use this method to retrieve the name of a shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the shared network in string format. A name can have a maximum of 32 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $sharednetwork = $sharednetwork->name();
```

networks( )

Use this method to retrieve the DHCP networks attribute of a shared network object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Network objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
my $network1 = Infoblox::DHCP::Network->new(
                                    "network" => "20.0.0.0/8",
                                );
my $network2 = Infoblox::DHCP::Network->new(
                                    "network" => "30.0.0.0/8",
                                );

#Get networks
my $sharednetwork = $sharednetwork->networks();
#Modify networks
my $sharednetwork = $sharednetwork->networks([$network1, $network2]);
```

network_view( )

Use this method to set or retrieve the network view of the DHCP shared network.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the DHCP shared network is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $sharednetwork->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$sharednetwork->network_view($nview);
```

nextserver( )

Use this method to set or retrieve the nextserver attribute of a shared network object. You can specify the name and/or IP address of the next server that the host needs to access in order to boot. This setting overrides the member-level settings. The default value is undefined which indicates that this attribute is inherited from the member-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

This option is overridden independently from Infoblox::DHCP::SharedNetwork->bootfile() and Infoblox::DHCP::SharedNetwork->bootserver().

Parameter

The next server IP address or name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A next server name can have a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get nextserver
my $nextserver = $sharednetwork->nextserver();
# Modify nextserver
$sharednetwork->nextserver("blue.domain.com");
#Un-override nextserver
$sharednetwork->nextserver(undef);
```

options( )

Use this method to set or retrieve the options value of a member DHCP server. DHCP options provide network configuration settings and various services available on the network for DHCP. This setting overrides the member-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array reference that contains Infoblox::DHCP::Option objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get options
my $options = $sharednetwork->options();
#Modify options
my $option1 = Infoblox::DHCP::Option->new(
    name  => "lease-time",
    value => 50
);

$sharednetwork->options([$option1]);
```

override_ddns_ttl( )

The override_ddns_ttl attribute controls whether the ddns_ttl value in the DHCP shared network object is used, instead of the grid default.

The override_ddns_ttl attribute can be specified explicitly. It is also set implicitly when ddns_ttl is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for ddns_ttl. Set the parameter to "false" to inherit the grid-level

setting for ddns_ttl.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_ddns_ttl
my $override_ddns_ttl=$sharednetwork->override_ddns_ttl( );
#Modifying override_ddns_ttl
$sharednetwork->override_ddns_ttl("true");
```

override_ignore_id( )

The override_ignore_id controls whether the ignore_id in the DHCP shared network is used, instead of the upper-level default.

The override_ignore_id can be specified explicitly. It is also set implicitly when ignore_id is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for ignore_id and ignore_mac_addresses. Set the parameter to "false" to inherit the upper-level setting for ignore_id and ignore_mac_addresses.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attrubute value
my $value=$sharednetwork->override_ignore_id();
#Modifying attribute value
$sharednetwork->override_ignore_id('true');
```

override_lease_scavenge_time( )

The override_lease_scavenge_time attribute controls whether the lease_scavenge_time value in the shared network is used, instead of the upper-level default.

The override_lease_scavenge_time attribute can be specified explicitly. It is also set implicitly when lease_scavenge_time is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the upper-level setting for lease_scavenge_time. Set the parameter to "false" to inherit the setting for lease_scavenge_time from the upper level.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_lease_scavenge_time
my $override_lease_scavenge_time=$sharednetwork->override_lease_scavenge_time( );
#Modifying override_lease_scavenge_time
$sharednetwork->override_lease_scavenge_time("true");
```

override_logic_filters( )

The override_logic_filters attribute controls whether the logic_filters value of the DHCP Shared Network is used, instead of the Grid default.

The override_logic_filters attribute can be specified explicitly. It is also set implicitly when logic_filters is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the Grid-level setting for logic_filters. Set the parameter to "false" to inherit the Grid-level setting for logic_filters.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_logic_filters
my $override_logic_filters=$sharednetwork->override_logic_filters( );
#Modifying override_logic_filters
$sharednetwork->override_logic_filters("true");
```

override_update_dns_on_lease_renewal( )

The override_update_dns_on_lease_renewal attribute controls whether the update_dns_on_lease_renewal value in the DHCP shared network object is used, instead of the grid default.

The override_update_dns_on_lease_renewal attribute can be specified explicitly. It is also set implicitly when update_dns_on_lease_renewal is set to a defined value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set the parameter to "true" to override the grid-level setting for update_dns_on_lease_renewal. Set the parameter to "false" to inherit the grid-level setting for update_dns_on_lease_renewal.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting override_update_dns_on_lease_renewal
my $override_update_dns_on_lease_renewal=$sharednetwork->override_update_dns_on_lease_renewal( );
#Modifying override_update_dns_on_lease_renewal
$sharednetwork->override_update_dns_on_lease_renewal("true");
```

pxe_lease_time( )

Use this method to set or retrieve the PXE lease time value of a shared network object. Some hosts use PXE (Preboot Execution Environment) to boot remotely from a server. To better manage your IP resources, set a different lease time for PXE boot requests. You can configure the DHCP server to allocate an IP address with a shorter lease time to hosts that send PXE boot requests, so IP addresses are not leased longer than necessary. This setting overrides the member-level settings. The default value is undefined, which indicates that this attribute is inherited from the member-level setting.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration, in seconds, that the update is cached. Zero indicates that the update is not cached. The default value is undefined

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get PXE Lease Time
```

```
my $pxe_lease_time = $sharednetwork->pxe_lease_time();
#Modify PXE Lease Time
$sharednetwork->pxe_lease_time(1100);
#Un-override PXE Lease Time
$sharednetwork->pxe_lease_time(undef);
```

update_dns_on_lease_renewal( )

The update_dns_on_lease_renewal attribute controls whether the DHCP server updates DNS when a DHCP lease is renewed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Setting this method to a defined value implicitly sets the override_update_dns_on_lease_renewal method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_update_dns_on_lease_renewal attribute to "false".

Note that when update_dns_on_lease_renewal is set to a defined value and override_update_dns_on_lease_renewal is set to "false", the last operation takes precedence. Thus the sequence $object->update_dns_on_lease_renewal("true"); $object->override_update_dns_on_lease_renewal("false"); will set override_update_dns_on_lease_renewal to "false", and the sequence $object->override_update_dns_on_lease_renewal("false"); $object->update_dns_on_lease_renewal("true"); will result in override_update_dns_on_lease_renewal="true".

Parameter

Specify "true" to set the update_dns_on_lease_renewal flag or "false" to deactivate/unset it.

The default value of this parameter is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get update_dns_on_lease_renewal
my $update_dns_on_lease_renewal=$sharednetwork->update_dns_on_lease_renewal( );
#Modify update_dns_on_lease_renewal
$sharednetwork->update_dns_on_lease_renewal("true");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP shared network object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP network object

```
my $network1 = Infoblox::DHCP::Network->new(
                                    "network" => "10.0.0.0/8",
                                );
my $network2 = Infoblox::DHCP::Network->new(
                                    "network" => "11.0.0.0/8",
                                );

my $response = $session->add($network1)
or die("Add \"10.0.0.0/8\"Network failed: ",
             $session->status_code() . ":" . $session->status_detail());
```

```
print "Network \"10.0.0.0/8\"added successfully\n";

my $response = $session->add($network2)
       or die("Add  \"11.0.0.0\"Network failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Network  \"11.0.0.0/8\",added successfully\n";
```

#Create a DHCP shared network object

```
my $sharednetwork1 = Infoblox::DHCP::SharedNetwork->new(
                                        "name"                          => "myname",
                                        "comment"                       => "add shared network",
                                        "networks"                      => [ $network1 , $network2 ],
                                        "disable"                       => "false",
                                        "authority"                     => "true",
                                        "enable_ddns"                   => "true",
                                        "ddns_use_option81"             => "true",
                                        "ddns_generate_hostname"        => "true",
                                        "ddns_server_always_updates"    => "true",
                                        "ddns_update_fixed_addresses"   => "true",
                                        "pxe_lease_time"                => "3600",
                                        "bootserver"                    => "someserver.com",
                                        "nextserver"                    => "3.3.3.3",
                                        "bootfile"                      => "bootfile.com",

                                        );

my $response = $session->add( $sharednetwork1 )
or die("Add Shared Network failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Shared Network added successfully\n";
```

#Search for a specific shared network object

```
#Search the network
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::SharedNetwork",
    "name"  => "my.*"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search Shared Network failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search Shared Network found at least 1 matching entry\n";
```

#Get and modify a shared network attribute

```
#GetShared Network through the session
my  @retrieved_objs = $session->get(
           object =>"Infoblox::DHCP::SharedNetwork" ,
           "name" => "myname"
        );

my $object = $retrieved_objs[0];

unless ($object) {
    die("Get Shared Network object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Shared Network found at least 1 matching entry\n";

#Modify attributes of the specified Network
$object->disable("true"); #Apply the changes
my $res = $session->modify($object) ;
if ( !$res)
{
    print "Modify Shared Network attribute failed: ".$session->status_code() . ":" . $session-
>status_detail();
}
else {
print "Shared Network object modified successfully \n";
}

#Un-override bootfile
$object->bootfile(undef);
```

```
#Un-override bootserver
$object->bootserver(undef);

#Un-override nextserver
$object->nextserver(undef);
```

#Remove a shared network object

```
 #Get Network object through the session
 my @retrieved_objs = $session->get(
           object  => "Infoblox::DHCP::SharedNetwork" ,
           name    => "myname"
    );

   my $object = $retrieved_objs[0];

   unless ($object) {
    die("Get Shared Network object failed: ",
        $session->status_code() . ":" . $session->status_detail());
    }

print "Get Shared Network object found at least 1 matching entry\n";

#Submit the shared network object for removal

$session->remove($object)
    or die("Remove Shared Network failed: ",
        $session->status_code() . ":" . $session->status_detail());

print "Shared Network removed successfully \n";

#Submit the network object for removal
my $response = $session->remove($network1)
or die("Remove \"10.0.0.0/8\"Network failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Network \"10.0.0.0/8\"remove successfully\n";

#Submit the network object for removal
my $response = $session->remove($network2)
       or die("Remove  \"11.0.0.0\"Network failed: ",
             $session->status_code() . ":" . $session->status_detail());

print "Network \"11.0.0.0/8\"remove successfully\

NAME

Infoblox::DHCP::SplitNetwork - Split network object.

DESCRIPTION

Once a network is created for DHCP, smaller subnetworks can be configured with larger netmasks. A larger netmask defines a larger number of network addresses and a smaller number of host addresses. Using Infoblox split network feature, the parent network can be split into multiple smaller networks without configuring each of the newly-created networks.

CONSTRUCTOR

```
my $split_network = Infoblox::DHCP::SplitNetwork->new(
            network                 => $Network|$IPv6Network,    #Required
            prefix                  => $num,                    #Required
            add_all_subnetworks     => "true" | "false",        #Optional / Default is "false"
            auto_create_reversezone => "true" | "false",        #Optional / Default is "false"
            prefix_collector_ipv6_network_addr => $string,      #Optional / Default is undefined
);
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that can be applied to a split network object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
    #Construct an object
    my $network = Infoblox::DHCP::Network->new(
                              network => "10.0.0.0/8",
                              comment => "add network",
                              );

    my $split_network = Infoblox::DHCP::SplitNetwork->new (
                        network                 => $network,
                        prefix                  => 12,
                        add_all_subnetworks     => "true",
                        );
    #Submit for addition
    my $response = $session->add( $split_network );
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute value of a split network object.

add_all_subnetworks( )

Use this method to set the add_all_subnetworks flag. If this flag is set, then all possible subnetworks will be added otherwise only networks with fixed addresses will be added.

Include the specific parameter to set the attribute value.

Parameter

Specify "true" to set add_all_subnetworks flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set add_all_subnetworks
$split_network->add_all_subnetworks("true");
```

auto_create_reversezone( )

Use this method to set the auto_create_reversezone flag. When set, this flag will automatically create reverse-mapping zones for the subnets.

Include the specified parameter to set the attribute value.

Parameter

Specify "true" to set auto_create_reversezone flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set auto_create_reversezone
$split_network->auto_create_reversezone("true");
```

network( )

Use this method to specify the network to be split.

Include the specified parameter to set the attribute value.

Parameter

The valid values are Infoblox::DHCP::Network or Infoblox::DHCP::IPv6Network objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Specify network
my $network = Infoblox::DHCP::Network->new(
                    network => "10.0.0.0/8",
                    comment => "add network",
                    );

$split_network->network($network);

#Specify ipv6 network
my $network = Infoblox::DHCP::IPv6Network->new(
                    network => "10::/48",
                    comment => "add network",
                    );

$split_network->network($network);
```

prefix( )

Use this method to specify the appropriate subnet mask for each subnet created after splitting the network.

Include the specified parameter to set the attribute value.

Parameter

Number with the subnet mask value. This value must be 1 greater than the subnet mask of the network to be split. The maximum value is 31 for IPv4 network or 127 for IPv6 network.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Specify prefix
$split_network->prefix(16);
```

prefix_collector_ipv6_network_addr( )

Use this method to specify the network that contains the DHCP IPv6FixedAddress and IPv6Range objects whose address_type is 'PREFIX' after a network is split.

Include the specified parameter to set the attribute value.

Parameter

The valid value is an IPv6 network address in string format and without any prefix bits appended.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

Example

```
#Set prefix_collector_ipv6_network_addr( )
$split_network->prefix_collector_ipv6_network_addr("2001::");
```

SAMPLE CODE

The following sample code demonstrates the split network operation. Also this sample code includes error handling for the operations.

#Preparation prior to splitting a network

```
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully.\n";

#Create network prior to splitting the network
my $network = Infoblox::DHCP::Network->new(
                            network => "20.0.0.0/8",
                            comment => "add network",
                            );
unless($network){
       die("Construct network object fail: ",
               Infoblox::status_code(). ":" .Infoblox::status_detail());
       }

print"Network object created successfully.\n";

#Verify if the network exists
my $object = $session->get(
               object  => "Infoblox::DHCP::Network",
               network => "20.0.0.0/8"
               );
unless($object){
       print"Network does not exist on server, safe to add the network.\n";
       $session->add($network)
               or die("Add network failed: ",
                       $session->status_code(). ":" .$session->status_detail());
       }
```

```
print"Network added successfully.\n";
```

#Split the network

```
my $split_network = Infoblox::DHCP::SplitNetwork->new (
                        network                 => $network,
                        prefix                  => 16,
                        add_all_subnetworks     => "true",
                        auto_create_reversezone => "true",
                      );
unless($split_network){
       die("Construct split network object fail: ",
                Infoblox::status_code(). ":" .Infoblox::status_detail());
       }

print"Split network object created successfully.\n";

#Split the network
$session->add( $split_network )
         or die("Split network fail:",
                    $session->status_code(). ":" .$session->status_detail());

print"Splited network successfully.\n";

####PROGRAM ENDS####
```

NAME

Infoblox::DHCP::Statistics - Manages DHCP statistics.

DESCRIPTION

The DHCP statistics object is used to view the DHCP statistics of the network in an Infoblox appliance.

CONSTRUCTOR

The Infoblox::DHCP::Statistics object is automatically generated upon the successful creation of the Infoblox::DHCP::Network object. It does not require manual construction.

SESSION METHODS

This section describes all the methods in an Infoblox::Session that can be applied to a DHCP statistics object.

Infoblox::Session->get( )

Use this method to retrieve the existing objects from an Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
 Apply the following attributes to get the DHCP statistics:

 statistics_object - Required. An object returned via Infoblox::Session->get() or Infoblox::Session-
>search(). Supported objects are Infoblox::DHCP::Network, Infoblox::DHCP::Range,
Infoblox::DHCP::SharedNetwork, and Infoblox::DHCP::MSSuperscope.
```

Example

```
# API can return more than 1 answer for DHCP::Statistics
# for each member of the network
my @network_stats = $session->get(
        object            => "Infoblox::DHCP::Statistics",
        statistics_object => $network);
```

METHODS

This section describes all the methods that can be used to retrieve the attribute values of a DHCP statistics object.

available_hosts( )

Use this method to retrieve the number of available IP addresses in the given network.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get available_hosts
my $available_hosts = $network_stats->available_hosts();
```

dynamic_hosts( )

Use this method to retrieve number of hosts which are assigned dynamic IP address.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get dynamic_hosts
my $dynamic_hosts = $network_stats->dynamic_hosts();
```

dhcp_utilization_status( )

Use this method to retrieve the DHCP utilization status.

Parameter

none

Returns

The method returns the attribute value. The returned value is one of "FULL", "HIGH", "LOW" or "NORMAL".

Example

```
#Get member
my $status = $network_stats->dhcp_utilization_status();
```

static_hosts( )

Use this method to retrieve the number of hosts with fixed addresses.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get static_hosts
my $static_hosts = $network_stats->static_hosts();
```

usage( )

Use this method to retrieve the percentage used of DHCP addresses in the network.

Parameter

none

Returns

The method returns the attribute value.

Example

```
#Get usage
my $usage = $network_stats->usage();
```

SAMPLE CODE

The following sample code demonstrates the get session method on a DHCP statistics object. Also, this sample code also includes error handling for the operations.

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;
```

#Preparation prior to getting DHCP statistics

```
#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

my $member = Infoblox::DHCP::Member->new(
    name     => "infoblox.localdomain",
    ipv4addr => "192.168.1.2",
);

unless($member) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create a Network View object
my $network_view = Infoblox::DHCP::View->new(
                    name => "my_network_view",
);
unless($network_view) {
             die("Construct Network View object failed: ",
                   Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network View object created successfully\n";

#Add the Network View object into the Infoblox appliance through a session
$session->add($network_view)
     or die("Add Network View object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Network View added successfully\n";

#Create the Network object with this member
my $network = Infoblox::DHCP::Network->new(
                    network => "1.0.0.0/255.0.0.0",
                    members => [ $member ],
                    network_view => $network_view,
);
unless($network) {
             die("Construct Network object failed: ",
                   Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Network object created successfully\n";

#Add the Network object into the Infoblox appliance through a session
$session->add($network)
     or die("Add Network object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Network added successfully\n";

#Create the DHCP Range object with this member
my $dhcp_range = Infoblox::DHCP::Range->new(
    network    => "1.0.0.0/8",
    start_addr => "1.0.0.1",
    end_addr   => "1.0.0.10",
    member     => $member,
    network_view => $network_view,
);
unless($dhcp_range) {
     die("Construct DHCP Range failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
```

```
}
print "DHCP range object created successfully\n";

$session->add($dhcp_range)
     or die("Add DHCP range object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP range added successfully\n";

#Create the Fixed Address object
my $fixed_address = Infoblox::DHCP::FixedAddr->new(
                                                    "network" => "1.0.0.0/8",
                                                    "ipv4addr" => "1.0.0.2",
                                                    "mac" => "22:22:22:22:22:22",
                                                    "network_view" => $network_view,
                                                    );
unless($fixed_address) {
     die("Construct DHCP Fixed address failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Fixed address object created successfully\n";

$session->add($fixed_address)
     or die("Add DHCP Fixed address object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Fixed address added successfully\n";
```

#Get the DHCP statistics

```
 my  @result_array = $session->get(
     object  => "Infoblox::DHCP::Network",
     network => "1.0.0.0/8",
     network_view => "my_network_view");

 my $network = $result_array[0];
 unless ($network) {
     die("Get Network failed: ",
         $session->status_code() . ":" . $session->status_detail());
 }

 @result_array = $session->get(
                               object  => "Infoblox::DHCP::Statistics",
                               statistics_object  => $network,
                              );

 my $network_stats = $result_array[0];
 unless ($network_stats) {
     die("Get Network statistics failed: ",
         $session->status_code() . ":" . $session->status_detail());
 }

 print "Get Network Statistics successful\n";
```

#Clean up # Remove the Network Statistics object that was just retrieved $session->remove($network_stats);

```
 # Retrieve and remove the Network View object
 my $network_view = $session->get(
         object => "Infoblox::DHCP::View",
         name => "my_network_view",
 );
 unless ($network_view) {
      die("Get Network View failed: ",
           $session->status_code() . ":" . $session->status_detail());
 }
 $session->remove($network_view);

NAME

Infoblox::DHCP::Template - DHCP Template object.

DESCRIPTION

The DHCP associates Infoblox::DHCP::RangeTemplate->offset(), Infoblox::DHCP::RangeTemplate->number_of_addresses() and Infoblox::DHCP::FixedAddrTemplate->offset(), Infoblox::DHCP::FixedAddrTemplate->number_of_addresses() with Infoblox::DHCP::NetworkTemplate. When optional fields offset/count are set in this object which is passed to Infoblox::DHCP::NetworkTemplate->fixed_address_templates() or Infoblox::DHCP::NetworkTemplate->range_templates() they are used instead of offset/number_of_addresses values in Infoblox::DHCP::RangeTemplate and Infoblox::DHCP::FixedAddrTemplate when creating Infoblox::DHCP::Network based on a template.

CONSTRUCTOR

```
my $template = Infoblox::DHCP::Template->new(
      name                  => $string,       #Required
      count                 => $num,          #Optional
      offset                => $num,          #Optional
);
```

MODULE METHODS

The following functions are available to be applied to a DHCP template object.

Infoblox::DHCP::NetworkTemplate->range_templates( )

Use this function to specify range templates for the DHCP network template object. See Infoblox::DHCP::NetworkTemplate->range_templates() for parameters and return values.

Example

```
        #Construct and add a DHCP Range Template object
        my $range_template = Infoblox::DHCP::RangeTemplate->new(
                name                  => "custom_range_template",
                offset                => "20", # this won't be used if specified in
    Infoblox::DHCP::Template
                number_of_addresses   => "10", # this won't be used if specified in
    Infoblox::DHCP::Template
        );
        $session->add($range_template);

        #Construct a DHCP Template object
        my $template = Infoblox::DHCP::Template->new(
                offset                => "10", # this will be used instead if specified
                count                 => "5", # this will be used instead if specified
                name                  => "custom_range_template"
        );

        # Configure DHCP Template on the DHCP Network template object
        $network_template->range_templates([$template]);
```

Infoblox::DHCP::NetworkTemplate->fixed_address_templates( )

Use this function to specify fixed address templates for the DHCP network template object. See Infoblox::DHCP::NetworkTemplate->fixed_address_templates() for parameters and return values.

Example

```
#Construct and add a DHCP Fixed Address Template object
my $fixed_address_template = Infoblox::DHCP::FixedAddrTemplate->new(
        name                => "custom_fixed_address_template",
        offset              => "20", # this won't be used if specified in
Infoblox::DHCP::Template
        number_of_addresses  => "10", # this won't be used if specified in
Infoblox::DHCP::Template
);
$session->add($fixed_address_template);

#Construct a DHCP Template object
my $template = Infoblox::DHCP::Template->new(
        offset              => "10", # this will be used instead if specified
        count               => "5", # this will be used instead if specified
        name                => "custom_fixed_address_template"
);

# Configure DHCP Template on the DHCP Network template object
$network_template->fixed_address_templates([$template]);
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP range template object.

name( )

Use this method to set or retrieve name of Infoblox::DHCP::RangeTemplate or Infoblox::DHCP::FixedAddrTemplate object assigned to this template object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of range template or fixed address template object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $template->name();
#Modify name
$template->name("custom_range_or_fixed_address_template_name");
```

count( )

Use this method to set or retrieve the number of addresses of the DHCP range or fixed address template. This value will be used instead of Infoblox::DHCP::RangeTemplate->number_of_addresses() or Infoblox::DHCP::FixedAddrTemplate->number_of_addresses() if specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The number of addresses in this template.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get count
my $count = $template->count();
#Modify count
$template->count("10");
```

offset( )

Use this method to set or retrieve the address offset of the DHCP range or fixed address template. This value will be used instead of Infoblox::DHCP::RangeTemplate->offset() or Infoblox::DHCP::FixedAddrTemplate->offset() if specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The address offset of this template.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get offset
my $offset = $template->offset();
#Modify offset
$template->offset("10");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a DHCP template object such as add, modify, and remove. Also, this sample includes error handling for the operations.

#Preparation prior to a DHCP Range object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;
#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
   master   => "192.168.1.2",
   username => "admin",
   password => "infoblox"
);

unless ($session) {
       die("Construct session failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create the DHCP Range template object

```
my $dhcp_range_template = Infoblox::DHCP::RangeTemplate->new(
        name                    => "custom_range_template",
        offset                  => "10",
        number_of_addresses     => "10",
);
unless($dhcp_range_template) {
       die("Construct DHCP Range template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Range template object created successfully\n";

#Add the DHCP Range template object into the Infoblox appliance through a session
$session->add($dhcp_range_template)
    or die("Add DHCP Range template object failed: ",
            $session->status_code() . ":" . $session->status_detail());
print "DHCP Range template object added to Infoblox appliance successfully\n";
```

#Create the Fixed Address template object

```
my $dhcp_fixed_address_template = Infoblox::DHCP::FixedAddrTemplate->new(
        name                    => "custom_fixed_address_template",
        offset                  => "10",
        number_of_addresses     => "10",
);
unless($dhcp_fixed_address_template) {
       die("Construct DHCP Fixed Address template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
```

```
}
print "DHCP Fixed Address template object created successfully\n";

#Add the DHCP Fixed Address Template  object into the Infoblox appliance through a session
$session->add($dhcp_fixed_address_template)
    or die("Add DHCP Fixed Address template object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "DHCP Fixed Address template object added to Infoblox appliance successfully\n";
```

#Create DHCP template objects

```
#Construct a DHCP Template object
my $tmpl1 = Infoblox::DHCP::Template->new(
         offset               => "10", # this will be used instead if specified
         count                => "5", # this will be used instead if specified
         name                 => "custom_range_template"
);

unless($tmpl1) {
       die("Construct DHCP template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP template object created successfully\n";

#Construct a DHCP Template objects
my $tmpl2 = Infoblox::DHCP::Template->new(
         offset               => "20", # this will be used instead if specified
         count                => "3", # this will be used instead if specified
         name                 => "custom_fixed_address_template"
);

unless($tmpl2) {
       die("Construct DHCP template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP template object created successfully\n";
```

#Add DHCP template to DHCP Network Template and insert it

```
my $network_template = Infoblox::DHCP::NetworkTemplate->new(
        name                   => "network_template",
        netmask                => "255.0.0.0",
        range_templates        => [ $tmpl1 ],
        fixed_address_templates => [ $tmpl2 ],
);
unless($network_template) {
       die("Construct DHCP Network template object failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DHCP Network template object created successfully\n";

#Add the DHCP Network template object into the Infoblox appliance through a session
$session->add($network_template)
    or die("Add Network template object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "DHCP Network template object added to Infoblox appliance successfully\n";

####PROGRAM ENDS####

NAME

Infoblox::DHCP::View - DHCP Network View object

DESCRIPTION

Network view provides the ability to manage multiple views of IP address spaces from NIOS. These address spaces could be overlapping or non-overlapping. When the network view is not specified during a write operation, the objects are automatically associated with the system-defined default network view.

A network view is a single routing domain, with its own networks and shared networks. You can manage the networks in one network view independently of the other network views.

CONSTRUCTOR

```
  my $network = Infoblox::DHCP::View->new(
     name                        => $string,
#Required
     comment                     => $string,
#Optional / Default is undefined
     ddns_zone_primaries         => [$ddns1, $ddns2, ... ],
#Optional / Default is undefined
     mgm_private                 => 'true' | 'false',
#Optional / Default is 'false'
     extensible_attributes       => { $string => $string|$num, $string => [ $string|$num, ...], ... },
#Optional / Default is undefined
     external_ddns_primaries     => [ $Nameserver1,$Nameserver2,...],
#Optional / Default is undefined
     internal_ddns_primaries     => [ $ForwardZone1,$ForwardZone2,...],
#Optional / Default is undefined
   );
```

SESSION METHODS

This section describes all the methods in an Infoblox::Session module that can apply to a DHCP Network View object.

Infoblox::Session->add( )

Use this method to add a network view object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $network_view = Infoblox::DHCP::View->new(
       name => "netview",
);

# Submit for adding network view
my $response = $session->add( $network_view );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching network view objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DHCP Network View object:

 name                  - Required. A name in string format.
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Example

```
 my  @result_array = $session->get(
      object        => "Infoblox::DHCP::View" ,
      name          => "netview"
 );

# get all DHCP view objects with a given extensible attribute
my @retrieved_objs = $session->get(
   object => "Infoblox::DHCP::View",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify a network object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify comment method.
$object->comment("My modified comment");
# Submit modification
my $response = $session->modify( $object );
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
# Get the object under the same name
my  @result_array = $session->get(
      object        => "Infoblox::DHCP::View" ,
      name          => "netview"
 );

# find the desired object from the retrieved list.
my $desired_network_view = $result_array[0];

# Submit for removal
my $response = $session->remove( $desired_network_view );
```

Infoblox::Session->search( )

Use this method to search for a DHCP Network View object in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a DHCP Network View object:

 name                  - Required. A name in string format (regular expression).
 extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for DHCP Network View object with name 'netview'
    my @retrieved_objs = $session->search(
      object       => "Infoblox::DHCP::Network",
      name         => "^netview\$"
    );

# search for DHCP views with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
   object => "Infoblox::DHCP::View",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that can be used to configure and retrieve the attribute values of a DHCP Network View object

associated_dns_views( )

Use this method to retrieve the list of DNS views associated with this network view. This list is read-only and cannot be set.

Parameter

None

Returns

Returns an array reference that contains Infoblox::DNS:View object(s).

Example

```
# Get associated_dns_views
my $associated_dns_views = $network_view->associated_dns_views()
```

cloud_info( )

Use this method to set or retrieve cloud API related information for the Infoblox::DHCP::View object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a Infoblox::Grid::CloudAPI::Info object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $network_view->cloud_info();
# Modify cloud_info
$network_view->cloud_info($cloud_info_object);
```

comment( )

Use this method to set or retrieve a descriptive comment of a DHCP Network View object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Enter a descriptive comment for the network view in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get comment
my $comment = $network_view->comment();
# Modify comment
```

```
$network_view->comment("add a network view");
```

ddns_zone_primaries( )

Use this method to set or retrieve an ordered list of zone primaries that will receive DDNS updates.

Parameter

A valid value is a reference to an array of Infoblox::DHCP::DDNS objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
$value = $network_view->ddns_zone_primaries();
# Modify the attribute value
$network_view->ddns_zone_primaries([$ddns]);
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DHCP view object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $firstview->extensible_attributes();
#Modify extensible attributes
$firstview->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

external_ddns_primaries( )

Use this method to set or retrieve the network view-level external_ddns_primaries value. This specifies the external zone that is updated dynamically. The DHCP server can send dynamic updates to a specified external name server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A valid value is an array reference that contains Infoblox::DNS::Nameserver object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get external_ddns_primaries
my $external_ddns_primaries = $network_view->external_ddns_primaries();

# Modify external_ddns_primaries
my $nameserver1 = Infoblox::DNS::Nameserver->new(
        ddns_zone => "ns1.del.com",
        ipv4addr  => "11.11.11.11",
    );
my $nameserver2 = Infoblox::DNS::Nameserver->new(
         ddns_zone => "3.2.1.in-addr.arpa",
         ipv4addr  => "22.22.22.22",
    );
```

```
# Nameserver with TSIG security
my $nameserver3 = Infoblox::DNS::Nameserver->new(
        ddns_zone     => 'grid_level.local',
        ipv4addr      => '10.102.30.122',
        TSIGalgorithm => 'HMAC-SHA256',
        TSIGname      => 'kk',
        TSIGkey       => '+NPBBVYjoNC32hfj8vepUw==',
);

# Nameserver with GSS-TSIG security
my $nameserver4 = Infoblox::DNS::Nameserver->new(
        ipv4addr               => '10.102.30.122',
        gss_tsig_domain        => 'AD-31.LOCAL',
        ddns_zone              => 'grid1_level.local',
        gss_tsig_dns_principal => 'DNS/w8s232-29.ad-31.local@AD-31.LOCAL'
);

$network_view->external_ddns_primaries([$nameserver1, $nameserver2, $nameserver3, $nameserver4]);

# Clear external_ddns_primaries list
$network_view->external_ddns_primaries([]);
```

mgm_private( )

Use this method to set or retrieve the flag that controls whether the object should be synced to the MGM or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to enable synchronization of the managed Grid with the MGM or 'false' to forbid it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get mgm_private value
my $value = $object->mgm_private();

#Modify mgm_private value
$object->mgm_private('true');
```

modify_vrf_assignment()

This method is used to assign (unassign) a list of the virtual networks (VRFs) to the network view.

Parameters

VRF membership modification mode: ASSIGN or UNASSIGN.

A valid list (array reference) that contains Infoblox::Grid::Member::Discovery::VRF object(s).

Returns

Returns true on success operation, otherwise false.

Example

```
# Get Network View
my $default_view = $session->get(object => 'Infoblox::DHCP::View', name => 'default');

# Get Infoblox::Grid::Member::Discovery::VRF objects
my $vrf1 = $session->get(object => 'Infoblox::Grid::Member::Discovery::VRF', name =>
'VirtualNetworkMember1');
my $vrf2 = $session->get(object => 'Infoblox::Grid::Member::Discovery::VRF', name =>
'VirtualNetworkMember2');

# Assign a list of the VRFs to the Network View
my $assign_result = $default_view->modify_vrf_assignment(
       vrfs => [ $vrf1, $vrf2 ],
       mode => 'ASSIGN'
);

# Unassign VRF from Network View
```

```
my $unassign_result = $default_view->modify_vrf_assignment(
        vrfs => [ $vrf2 ],
        mode => 'UNASSIGN'
);

# Check of VRF assignment via Infoblox::Grid::Member::Discovery::VRF object
$vrf = $session->get(object => 'Infoblox::Grid::Member::Discovery::VRF', name =>
'VirtualNetworkMember1');

# Get current network view name associated with VRF
print $vrf->network_view;
```

internal_ddns_zones( )

Use this method to set or retrieve forward mapping zones which are being served in the grid. Only an authoritative zone can be assigned to this list. All other types of zones will generate an error.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A valid value is an array reference that contains Infoblox::DNS::Zone object(s).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get internal_ddns_zones
my $internal_ddns_zones = $network_view->internal_ddns_zones();

# Modify internal_ddns_zones
my $nameserver1 = Infoblox::DNS::Nameserver->new(
        name     => "ns1.del.com",
        ipv4addr => "11.11.11.11",
    );
my $nameserver2 = Infoblox::DNS::Nameserver->new(
        name     => "test",
        ipv6addr => "2006::b671",
    );
my $zone1 = Infoblox::DNS::Zone->new(
        name     => "test1.com",
        primary  => [$nameserver1],
        secondaries => [$nameserver2],
    );
my $zone2 = Infoblox::DNS::Zone->new(
        name     => "test2.com",
    );
$network_view->internal_ddns_zones([$zone1, $zone2]);

# Clear internal_ddns_zones list
$network_view->internal_ddns_zones([]);
```

internal_updates_view( )

Use this method to specify or retrieve the internal updates DNS view value of a network view. When you enable the appliance to send updates to grid members, you must specify which DNS view receives the updates.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A valid value is an Infoblox::DNS::View object for internal dynamic updates.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get internal_updates_view
my $internal_updates_view = $network_view->internal_updates_view();
# Modify internal_updates_view
```

```
my $otherview = Infoblox::DNS::View->new(
        name => "other",
    );
$network_view->internal_updates_view($otherview);
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $view->ms_ad_user_data();
```

name( )

Use this method to set or retrieve the name of a DHCP Network View object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The name of the network view is in string format with a maximum of 64 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get name
my $name = $network_view->name()
# Modify name
$network_view->name("netview_renamed");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DHCP Network View insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DHCP Network View object

```
my $network_view = Infoblox::DHCP::View->new(
           name     => "netview",
          );

my $response = $session->add($network_view)
       or die("Add Network View failed: ",
```

```
            $session->status_code() . ":" . $session->status_detail());

print "Network View added successfully\n";
```

#Search for a specific Network View

```
#Search the network view
my @retrieved_objs = $session->search(
    object  => "Infoblox::DHCP::View",
    name => '^netview$',
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search Network View failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search Network found at least 1 matching entry\n";
```

#Get and modify a Network View attribute

```
#Get Network View through the session
my  @retrieved_objs = $session->get(
           object => "Infoblox::DHCP::View" ,
           name   => "netview",
        );

my $object = $retrieved_objs[0];

unless ($object) {
    die("Get Network View object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get Network View found at least 1 matching entry\n";

#Modify one of the attributes of the specified Network View attribute
$object->comment("updated comment"); #Apply the changes

$session->modify($object)
    or die("Modify Network View attribute failed: ",
           $session->status_code() . ":" . $session->status_detail());

print "Network View object modified successfully \n";
```

#Remove a Network View Object

```
 #Get Network View object through the session
 my @retrieved_objs = $session->get(
           object  => "Infoblox::DHCP::View" ,
           name    => "netview",
       );

   my $object = $retrieved_objs[0];

   unless ($object) {
    die("Get Network View object failed: ",
        $session->status_code() . ":" . $session->status_detail());
    }

print "Get Network View object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove Network View failed: ",
        $session->status_code() . ":" . $session->status_detail());

print "Network View removed successfully \n";

NAME

Infoblox::DNS::AllRecords - A synthetic object used to return all record object types belonging to a zone.

DESCRIPTION

By searching on this object, all the record objects associated with a specific zone can be retrieved

---

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DNS AllRecords object.

Infoblox::Session->search( )

Use this method to search for record objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
 Apply the following attributes to search for a DNS AllRecords object:

  zone           - Required. A zone name in FQDN format.
  creator        - Optional. The creator of the record. The valid values are 'SYSTEM', 'DYNAMIC' and
'STATIC'.
  ddns_principal - Optional. The GSS-TSIG principal that owns the record.
  view           - Optional. The DNS view in which the records are located. By default, the default
DNS views is searched.
  name           - Optional. The name of the matched record. (regular expression).
  reclaimable    - Optional. The flag that indicates whether the record is reclaimable or not.
  type           - Optional. The type of record to search for. By default, all record types are
searched. Following is the list of valid values for this search field:

                 'All A Records',
                 'All AAAA Records',
                 'All Alias Records',
                 'All Bulk Host',
                 'All CNAME Records',
                 'All DNAME Records',
                 'All DNSKEY Records',
                 'All DS Records',
                 'All DTCLBDN Records',
                 'All Host Address',
                 'All Host Alias',
                 'All Host Records',
                 'All IPV6 Host Address',
                 'All LBDN Records',
                 'All MX Records',
                 'All NAPTR Records',
                 'All NS Records',
                 'All NSEC Records',
                 'All NSEC3 Parameter Records',
```

```
                    'All NSEC3 Records',
                    'All PTR Records',
                    'All RSIG Records',
                    'All Records',
                    'All SEC Records',
                    'All SOA Records',
                    'All SRV Records',
                    'All TLSA Records',
                    'All Shared A Records',
                    'All Shared AAAA Records',
                    'All Shared MX Records',
                    'All Shared SRV Records',
                    'All Shared TXT Records',
                    'All TXT Records',
```

Example

```
# search for all records in the "domain.com" zone in the default DNS view
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::AllRecords",
    zone   => 'domain.com',
);

# search for all TXT records that match the 'rec' name in the "domain.com" zone in the default DNS
view
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::AllRecords",
    zone   => 'domain.com',
    type   => 'All TXT Records',
    name   => 'rec',
);
```

METHODS

This section describes all the methods that you can use to retrieve the attribute values of an AllRecords object. All methods are read-only and cannot be set.

comment( )

Use this method to retrieve the descriptive comment of the record associated with the AllRecords object.

Returns

The method returns the attribute value.

Example

```
#Get comment
my $comment = $allrecord->comment();
```

creator( )

Use this method to retrieve the resource record creator.

Returns

The method returns the attribute value.

Example

```
#Get creator
my $creator = $allrecord->creator();
```

ddns_principal( )

Use this method to retrieve the GSS-TSIG principal that owns the record.

Returns

The method returns the attribute value.

Example

```
#Get ddns_principal
my $ddns_principal = $allrecord->ddns_principal();
```

ddns_protected( )

Use this method to retrieve the flag that indicates whether this record is protected from DDNS updates or not.

Returns

The method returns the attribute value.

Example

```
#Get ddns_protected
my $ddns_protected = $allrecord->ddns_protected();
```

disable( )

Use this method to retrieve the disable flag of of the record associated with the AllRecords object (if present).

Returns

The method returns the attribute value.

Example

```
#Get disable
my $disable = $allrecord->disable();
```

dtc_obscured( )

Use this method to retrieve the LBDN object that obscures this record. This is a read-only attribute.

Parameter

None

Returns

The method returns attribute value.

Example

```
#Get dtc_obscured
my $dtc_obscured = $allrecord->dtc_obscured();
```

last_queried( )

Use this method to retrieve the time the associated record was last queried on.

Returns

The method returns the attribute value, the number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_queried
my $last_queried = $allrecord->last_queried();
```

name( )

Use this method to retrieve the name of of the record associated with the AllRecords object. Note that this value could differ from the value of the associated record's name field.

Returns

The method returns the attribute value.

Example

```
#Get name
my $name = $allrecord->name();
```

reclaimable( )

Use this method to retrieve the flag that indicates whether the record is reclaimable or not.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get reclaimable
my $reclaimable = $object->reclaimable();
```

record( )

Use this method to retrieve the record object associated with the AllRecords object.

This object is considered a 'partial' object. See Infoblox::Session->fill_partial_object() for more information on how it can be converted to a 'full' API object.

If the AllRecords object refers to a record not currently supported in the Perl API, the member value will be undefined.

Returns

The method returns the attribute value.

Example

```
#Get record
my $record = $allrecord->record();
```

ttl( )

Use this method to retrieve the TTL value of of the record associated with the AllRecords object (if present).

Returns

The method returns the attribute value.

Example

```
#Get ttl
my $ttl = $allrecord->ttl();
```

type( )

Use this method to retrieve the type of the record associated with the AllRecords object. This is a descriptive string that identifies the record to which this AllRecords object refers. (For example, 'A record', 'MX record', ...)

Returns

The method returns the attribute value.

Example

```
#Get type
my $type = $allrecord->type();
```

view( )

Use this method to retrieve the DNS view name of the record associated with the AllRecords object.

Returns

The method returns the attribute value.

Example

```
#Get view
my $view = $allrecord->view();
```

zone( )

Use this method to retrieve the zone name of the record associated with the AllRecords object.

Returns

The method returns the attribute value.

Example

```
#Get zone
my $zone = $allrecord->zone();
```

SAMPLE CODE

```
 In cases where a large number of matching records exist on the appliance, only a limited number will be
returned
 at a time. If all of the matching records are required, please consider using the paging support via
Infoblox::Cursor.

 #Code sample fragment Starts:

    $cursor=$session->new_cursor(
                                 fetch_size => 100,
                                 object => "Infoblox::DNS::AllRecords",
                                 zone   => 'domain.com',
                                 view   => 'default',
                                );

    while ($current_record = $cursor->fetch()) {
        # $current_record will contain a matching AllRecords object
    }

    # All matching AllRecords will be returned
    # when the cycle ends.

 If you want full record objects for some of the above, you can add the following code

 #Code sample fragment Starts:

     if( ... some criteria ...) {
         push @temp, $current_record->record();
     }

 ####Code Fragment Ends####

 inside the while() cycle and afterwards call

 #Code sample fragment Starts:

 @full_record_objects=$session->fill_partial_object(\@temp);

 ####Code Fragment Ends####

 to fill the wanted objects.
```

NAME

Infoblox::DNS::AllRPZRecords - A synthetic object used to return record object types that belong to a Response Policy Zone.

DESCRIPTION

By searching on this object, all record objects associated with a specific zone can be retrieved.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DNS AllRPZRecords object.

Infoblox::Session->search( )

Use this method to search for record objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
 Apply the following attributes to search for a DNS AllRPZRecords object:

  zone       - Required. A Response Policy Zone name in FQDN format.
  view       - Optional. The DNS view in which the records are located. By default, the default DNS
view is searched.
  name       - Optional. The name of the matched record. (regular expression).
  type       - Optional. The type of record to search for. By default, all record types are searched.
Following is the list of valid values for this search field:

                'All Records',
                'All A Records',
                'All AAAA Records',
                'All CNAME Records',
                'All IP Address Record',
                'All MX Record',
                'All NAPTR Record',
                'All PTR Record',
                'All SRV Record',
                'All TXT Record',
                'All A IP Address Record',
                'All AAAA IP Address Record'

  rpz_rule  - Optional. The Response Policy Zone rule type of record to search for. By default, all
rule types are searched. Following is the list of valid values for this search field:

                'PASSTHRUIPADDR',
                'PASSTHRUDOMAIN',
                'BLOCKNXDOMAINIPADDR',
                'BLOCKNXDOMAINDOMAIN',
                'BLOCKNODATAIPADDR',
                'BLOCKNODATADOMAIN',
                'SUBSTITUTE_CNAME',
                'SUBSTITUTE_A_RECORD',
                'SUBSTITUTE_AAAA_RECORD',
```

```
                    'SUBSTITUTE_MX_RECORD',
                    'SUBSTITUTE_PTR_RECORD',
                    'SUBSTITUTE_NAPTR_RECORD',
                    'SUBSTITUTE_SRV_RECORD',
                    'SUBSTITUTE_TXT_RECORD',
                    'SUBSTITUTE_IPV4ADDRESS_RECORD',
                    'SUBSTITUTE_IPV6ADDRESS_RECORD'
                    'SUBSTITUTE_IPADDR_CNAME'
```

Example

```
# search for all RPZ records in the "rpz.com" zone in the default DNS view
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::AllRPZRecords",
    zone   => 'rpz.com',
);

# search for all TXT records that match the 'rec' name in the "rpz.com" zone in the default DNS view
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::AllRPZRecords",
    zone   => 'rpz.com',
    type   => 'All TXT Records',
    name   => 'rec',
);

# search for all PASSTHRUDOMAIN Response Policy Rule type in the "rpz.com" zone in the default DNS
view
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::AllRPZRecords",
    zone   => 'rpz.com',
    rpz_rule   => 'PASSTHRUDOMAIN',
);
```

METHODS

This section describes all the methods that you can use to retrieve the attribute values of an AllRPZRecords object. All methods are read-only and cannot be set.

alert_type( )

Use this method to retrieve the alert type of the record associated with the AllRPZRecords object.

Returns

The method returns the attribute value.

Example

```
# Get alert_type
my $alert_type = $allrpzrecord->alert_type();
```

comment( )

Use this method to retrieve the descriptive comment of the record associated with the AllRPZRecords object.

Returns

The method returns the attribute value.

Example

```
#Get comment
my $comment = $allrpzrecord->comment();
```

expiration_time( )

Use this method to retrieve expiration time of the record associated with the AllRPZRecords object.

Returns

The method returns the attribute value.

Example

```
#Get expiration_time
my $expiration_time = $allrpzrecord->expiration_time();
```

disable( )

Use this method to retrieve the disable flag of the record associated with the AllRPZRecords object (if present).

Returns

The method returns the attribute value.

Example

```
#Get disable
my $disable = $allrpzrecord->disable();
```

last_updated( )

Use this method to retrieve the time the record associated with the AllRPZRecords object was last updated at.

Returns

The method returns the attribute value.

Example

```
#Get last_updated
my $last_updated = $allrpzrecord->last_updated();
```

name( )

Use this method to retrieve the name of of the record associated with the AllRPZRecords object. Note that this value could differ from the value of the associated record's name field.

Returns

The method returns the attribute value.

Example

```
#Get name
my $name = $allrpzrecord->name();
```

record( )

Use this method to retrieve the record object associated with the AllRPZRecords object.

This object is considered a 'partial' object. See Infoblox::Session->fill_partial_object() for more information on how it can be converted to a 'full' API object.

If the AllRPZRecords object refers to a record not currently supported in the Perl API, the member value will be undefined.

Returns

The method returns the attribute value.

Example

```
#Get record
my $record = $allrpzrecord->record();
```

ttl( )

Use this method to retrieve the TTL value of the record associated with the AllRPZRecords object (if present).

Returns

The method returns the attribute value.

Example

```
#Get ttl
my $ttl = $allrpzrecord->ttl();
```

type( )

Use this method to retrieve the type of record associated with the AllRPZRecords object. This is a descriptive string that identifies the record to which this AllRPZRecords object refers. (For example, 'A record', 'MX record', ...)

Returns

The method returns the attribute value.

Example

```
#Get type
my $type = $allrpzrecord->type();
```

view( )

Use this method to retrieve the DNS view name of the record associated with the AllRPZRecords object.

Returns

The method returns the attribute value.

Example

```
#Get view
my $view = $allrpzrecord->view();
```

zone( )

Use this method to retrieve the Response Policy Zone name of the record associated with the AllRPZRecords object.

Returns

The method returns the attribute value.

Example

```
#Get zone
my $zone = $allrpzrecord->zone();
```

rpz_rule( )

Use this method to retrieve the Response Policy Zone rule type of the record associated with the AllRPZRecords object.

Returns

The method returns the attribute value.

Example

```
#Get rule type
my $rpz_rule = $allrpzrecord->rpz_rule();
```

SAMPLE CODE

```
 In cases where a large number of matching records exist on the appliance, only a limited number will be
returned
 at a time. If all of the matching records are required, please consider using the paging support via
Infoblox::Cursor.

 #Code sample fragment Starts:

    $cursor=$session->new_cursor(
                                 fetch_size => 100,
                                 object => "Infoblox::DNS::AllRPZRecords",
                                 zone   => 'rpz.com',
                                 view   => 'default',
                                );

    while ($current_record = $cursor->fetch()) {
        # $current_record will contain a matching AllRPZRecords object
    }

    # All matching AllRPZRecords will be returned
    # when the cycle ends.

 If you want full record objects for some of the above, you can add the following code

 #Code sample fragment Starts:

     if( ... some criteria ...) {
         push @temp, $current_record->record();
     }

 ####Code Fragment Ends####
```

```
inside the while() cycle and afterwards call
#Code sample fragment Starts:
@full_record_objects=$session->fill_partial_object(\@temp);
####Code Fragment Ends####
to fill the wanted objects.
```

NAME

Infoblox::DNS::BulkHost - Create a group of hosts.

DESCRIPTION

If you need to add a large number of hosts, you can have the Infoblox appliance add them as a group and automatically assign host names based on a range of IP addresses and name format applied to it. This group of hosts is referred to as a BulkHost. The Infoblox appliance uses the name space bulk-xx-xx-xx-xx for BulkHosts, so this name should not be used for CNAMEs and host aliases because doing so causes conflicts. Before adding a BulkHost, make sure that no CNAMEs or host aliases uses this name.

Note that you must specify only one view for the attribute "views".

CONSTRUCTOR

```
my $bulkhost = Infoblox::DNS::BulkHost->new(
    end_addr           => $ipv4addr,              #Required
    prefix             => $string,                #Required
    start_addr         => $ipv4addr,              #Required
    zone               => $fqdn,                  #Required
    comment            => $string,                #Optional / Default is empty
    disable            => "true" | "false",       #Optional / Default "false"
    name_template      => $string | undef,        #Optional / Default is undefined
    reverse            => "true" | "false",       #Optional / Default "false"
    ttl                => $num | undef,           #Optional / Default is undefined
    use_name_template  => "true" | "false",       #Optional / Default is "false"
    views              => [$View1]                        #Optional / Default is "default" view
    extattrs           => { $string => $extattr, ... },      #Optional / Default is undefined
);
```

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DNS BulkHost record object.

Infoblox::Session->add( )

Use this method to add a BulkHost record object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return

values.

Example

```
#Construct an object
my $bulk_host = Infoblox::DNS::BulkHost->new(
    zone               => "domain.com",
    comment            => "add bulk host",
    prefix             => "prefix",
    start_addr         => "1.0.0.1",
    end_addr           => "1.0.0.5",
    reverse            => "true",
    use_name_template  => "true",
    name_template      => "Three Octets"
);
#Submit for addition
my $response = $session->add($bulk_host)
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DNS BulkHost object:

 zone - Optional. A zone name in string format.
 prefix     - Optional. Prefix of the bulk host.
 start_addr - Optional. Start address of the bulk host.
 end_addr   - Optional. End address of the bulk host.
 comment    - Optional. A comment in string format.
 view - Optional. The DNS view in which the bulk host record is located. The default is all DNS
views.
 ttl - Optional. Time to Live (TTL) value in integer format.
 name_template - Optional. The bulk host name template in string format.
 disable - Optional. Disable flag of a DNS BulkHost record in boolean format.
 use_name_template - Optional. Use name template flag of a DNS BulkHost record in boolean format.
 reverse - Optional. Reverse flag of a DNS BulkHost record in boolean format.
 extattrs     - Optional. A hash reference containing extensible attributes.
```

Example

```
#Get BulkHost object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DNS::BulkHost",
    zone   => "domain.com",
    prefix => "prefix",
    start_addr => "1.0.0.2",
    end_addr => "1.0.0.6".
    view => "default",
    ttl => 3600,
    name_template => "Three Octets",
    disable => "false",
    use_name_template => "true",
    reverse => "true"
);
```

Infoblox::Session->modify( )

Use this method to modify a BulkHost record object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the prefix.
$bulk_host->prefix("test");
#Submit modification
my $response = $session->modify( $bulk_host );
```

Infoblox::Session->remove( )

Use this method to remove a BulkHost record object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific BulkHost record object, and then submit this object for removal.

Example

```
#Get BulkHost object through the session
my @retrieved_objs = $session->get(
    object     => "Infoblox::DNS::BulkHost",
    zone       => "domain.com",
    prefix     => "test",
    start_addr => "1.0.0.1",
    end_addr   => "1.0.0.5"
);
#Find the desired object from the retrieved list.
my $desired_bulk = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove( $desired_bulk );
```

Infoblox::Session->search( )

Use this method to search for Bulk Host objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
Apply the following attributes to search for a specific Bulk Host object:

 zone       - Optional. Zone name in FQDN format (regular expression).
 prefix     - Optional. Prefix of the bulk host (regular expression).
 start_addr - Optional. Start address of the bulk host.
 end_addr   - Optional. End address of the bulk host.
 comment    - Optional. A comment in string format (regular expression).
 view       - Optional. The DNS view in which the bulk host record is located (regular expression).
The default is all DNS views.

 ttl - Optional. Time to Live (TTL) value in integer format.
 name_template - Optional. The bulk host name template in string format.
                 This is B<not> a regular expression, so do not specify this
                 value to ".*" if you want to obtain BulkHost records with all
                 name templates. Just leave this field unspecified.
 disable - Optional. Disable flag of a DNS BulkHost record in boolean format.
 use_name_template - Optional. Use name template flag of a DNS BulkHost record in boolean format.
 reverse - Optional. Reverse flag of a DNS BulkHost record in boolean format.
 extattrs     - Optional. A hash reference containing extensible attributes.
```

Example

```
# search for all Bulk Host objects that start with "prefix"
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::BulkHost",
    prefix => "prefix.*"
);
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a BulkHost object.

cloud_info( )

Use this method to retrieve cloud API related information for the Infoblox::DNS::BulkHost object.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $object->cloud_info();
```

comment( )

Use this method to set or retrieve the descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $bulkhost->comment();
#Modify comment
$bulkhost->comment("Modifying the BulkHost comment");
```

disable( )

Use this method to set or retrieve the disable flag of a DNS BulkHost record.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value for this field is false. The DNS BulkHost record is enabled.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $bulkhost->disable();
#Modify disable
$bulkhost->disable("true");
```

dns_prefix( )

Use this method to retrieve the prefix, in punycode format, for the bulk host. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $bulkhost->dns_prefix();
```

end_addr( )

Use this method to set or retrieve the last IP address in the address range of the BulkHost.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IP address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get end_addr
my $end_addr = $bulkhost->end_addr();
#Modify end_addr
$bulkhost->end_addr("1.0.0.6");
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DNS BulkHost object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $bulkhost->extattrs();
#Modify extattrs
$bulkhost->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

last_queried( )

Use this method to retrieve the time when the associated record was last queried. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_queried
my $last_queried = $bulkhost->last_queried();
```

name_template( )

Use this method to set or retrieve the bulk host name template.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is undefined which indicates the grid level default bulk host name format is used.

Specify a bulk host name format value to override the name format at the grid level.

Parameter

The name of a bulk host name format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name_template
my $name_template = $bulkhost->name_template();
#Modify name_template
$bulkhost->name_template("Three Octets");
```

prefix( )

Use this method to set or retrieve the prefix for the BulkHost. The prefix is the name (or a series of characters) inserted at the beginning of each host name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The attribute value can be in unicode format.

Parameter

Desired text with the prefix for the BulkHost. The sum of the bulk host prefix length and suffix length must not exceed 63

characters. If it does, the appliance displays an error message indicating the number of characters that you must remove to make a valid prefix.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get prefix
my $prefix = $bulkhost->prefix();
#Modify prefix
$bulkhost->prefix("test");
```

reverse( )

Use this method to set or retrieve the reverse flag of the BulkHost record.

If the flag is enabled, reverse mapping `address(es)` are added automatically if a reverse mapping zone exists.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get reverse
my $reverse = $bulkhost->reverse();
#Modify reverse
$bulkhost->reverse("true");
```

start_addr( )

Use this method to set or retrieve the first IP address in the address range of the BulkHost.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IP address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get start_addr
my $start_addr = $bulkhost->start_addr();
#Modify start_addr
$bulkhost->start_addr("1.0.0.2");
```

ttl( )

Use this method to set or retrieve the Time to Live (TTL) value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is undefined which indicates that the record inherits the TTL value of the zone.

Specify a TTL value to override the TTL value at the zone level.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration in seconds that the record is cached. Zero indicates that the record should not be cached.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ttl
my $ttl = $bulkhost->ttl();
#Modify ttl
$bulkhost->ttl(3600);
```

use_name_template( )

Use this method to set or retrieve the use_name_template flag value. This setting overrides the grid level bulk host name format.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get use_name_template
my $use_name_template = $bulkhost->use_name_template();
#Modify use_name_template
$bulkhost->use_name_template("true");
```

views( )

Use this method to set or retrieve the view of a BulkHost.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" view, which means the BulkHost object is located under the default view.

Parameter

Array reference of defined Infoblox::DNS::View objects.

Note that the array size must be 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get views
my $views = $bulkhost->views();
#Modify views
$bulkhost->views([$view1]);
```

zone( )

Use this method to set or retrieve the zone name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A zone name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host_name followed by the domain name (example: abc.com). A host_name can have a maximum of 256 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get zone
my $zone = $bulkhost->zone();
#Modify zone
$bulkhost->zone("test.com");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a Bulk Host object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
               master   => "192.168.1.2", #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";

#Create the zone prior to a BulkHost insertion
my $zone = Infoblox::DNS::Zone->new(
    name    => "domain.com",
    email   => "admin\@domain.com",
    comment => "add a zone domain.com",
    );
unless ($zone) {
   die("Construct zone failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Zone object created successfully\n";

#Verify if the zone exists
my $object = $session->get(object => "Infoblox::DNS::Zone", name => "domain.com");
unless ($object) {
   print "Zone does not exist on server, safe to add the zone\n";
   $session->add($zone)
      or die("Add zone failed: ",
             $session->status_code() . ":" . $session->status_detail());
}
print "Zone added successfully\n";
```

#Create a BulkHost object

```
my $bulk_host = Infoblox::DNS::BulkHost->new(
    zone               => "domain.com",
    comment            => "add bulk host",
    prefix             => "prefix",
    start_addr         => "1.0.0.1",
    end_addr           => "1.0.0.5",
    use_name_template  => "true",
    name_template      => "Three Octets",
    reverse            => "true"
    );
unless($bulk_host) {
     die("Construct BulkHost failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "BulkHost object created successfully\n";

#Add the BulkHost object to Infoblox Appliance through a session
$session->add($bulk_host)
```

```
    or die("Add BulkHost object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "Bulk Host object added to server successfully\n";
```

#Search for a specific DNS BulkHost record

```
#Search for all BulkHost objects in the zone "domain.com"
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::BulkHost",
    zone   => "domain.com"
);
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search Bulk Host object failed: ",
              $session->status_code() . ":" . $session->status_detail());
}
print "Search Bulk Host object found at least 1 matching entry\n";

#Search for all BulkHost objects that start with prefix as "prefix"
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::BulkHost",
    prefix => "prefix.*"
);
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search Bulk Host object failed: ",
              $session->status_code() . ":" . $session->status_detail());
}
print "Search Bulk Host object found at least 1 matching entry\n";

#Search for all BulkHost objects with specific start_addr
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::BulkHost",
    start_addr => "1.0.0.1",
);
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search Bulk Host object failed: ",
              $session->status_code() . ":" . $session->status_detail());
}
print "Search Bulk Host object found at least 1 matching entry\n";

#Search for all BulkHost objects with specific end_addr
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::BulkHost",
    end_addr => "1.0.0.5",
);
my $object = $retrieved_objs[0];

unless ($object) {
       die("Search Bulk Host object failed: ",
              $session->status_code() . ":" . $session->status_detail());
}
print "Search Bulk Host object found at least 1 matching entry\n";
```

#Get and modify a BulkHost object

```
#Get BulkHost object through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DNS::BulkHost",
    zone   => "domain.com",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get BulkHost object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get BulkHost object found at least 1 matching entry\n";

#Modify one of the attributes of the specified BulkHost object
$object->prefix("test");

#Apply the changes
$session->modify($object)
```

```
    or die("Modify BulkHost object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "BulkHost object modified successfully \n";
```

#Remove a BulkHost object

```
#Get BulkHost object through the session
my @retrieved_objs = $session->get(
    object     => "Infoblox::DNS::BulkHost",
    zone       => "domain.com",
    prefix     => "test",
    start_addr => "1.0.0.1",
    end_addr   => "1.0.0.5"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get BulkHost object failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Get BulkHost object found at least 1 matching entry\n";

#Submit the object for removal
$session->remove($object)
    or die("Remove  BulkHost object failed: ",
        $session->status_code() . ":" . $session->status_detail());
print "BulkHost object removed successfully \n";

####PROGRAM ENDS####

NAME

Infoblox::DNS::DDNS::PrincipalCluster - A DDNS Principal Cluster object.

DESCRIPTION

The DDNS Principal Cluster object represents a set of principals such that any principal in a DDNS Principal Cluster can update records created by any other principal in the same cluster.

CONSTRUCTOR

```
my $cluster = Infoblox::DNS::DDNS::PrincipalCluster->new(
    name       => $string,                    # Required
    group      => $string,                    # Required
    comment    => $string,                    # Optional / Default is undefined
    principals => [$string1, $string2, ...], # Optional / Default is undefined
);
```

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a DDNS Principal Cluster object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#create DDNS principal cluster group

my $cluster_group = Infoblox::DNS::DDNS::PrincipalCluster::Group->new(
    name => 'cluster_group',
);

#submit for addition
my $response = $session->add($cluster_group);

#construct an object
my $object = Infoblox::DNS::DDNS::PrincipalCluster->new(
   name  => 'cluster1',
   group => 'cluster_group',
);

#submit for addition
my $response = $session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

 name    - Optional. A DDNS Principal cluster name in a string format.
 comment - Optional. A DDNS Principal cluster comment.
 group   - Optional. A DDNS Principal cluster group name.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::DNS::DDNS::PrincipalCluster',
    name   => 'cluster1',
    group  => 'cluster_group',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the comment.
$object->comment('this is a modified comment');
#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => 'Infoblox::DNS::DDNS::PrincipalCluster',
    name   => 'cluster1',
);
#Find the desired object from the retrieved list.
my $desired_cluster = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove($desired_cluster);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

 name    - Optional. A DDNS Principal Cluster name in a string format.
 comment - Optional. A DDNS Principal Cluster comment.
 group   - Optional. A DDNS Principal cluster group name.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::DNS::DDNS::PrincipalCluster',
    name   => 'group11',
);
```

MODULE METHODS

Infoblox::DNS::DDNS::PrincipalCluster::Group->clusters( )

Use this method to retrieve a list of DDNS Principal Clusters. See Infoblox::DNS::DDNS::PrincipalCluster::Group->clusters() for parameters and return values.

Example

```
#get clusters value
```

```
my $clusters = $object->clusters();
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a comment in string format (UTF-8) with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get comment value
my $comment = $object->comment();

#modify comment value
$object->comment('desired comment');
```

group( )

Use this method to set or retrieve the DDNS Principal Cluster group the cluster associated with.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a DDNS Principal Cluster group name in string format (UTF-8) with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get group value
my $group = $object->group();

#modify group value
$object->group('desired_group');
```

name( )

Use this method to set or retrieve the DDNS Principal Cluster name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get name value
my $name = $object->name();
```

```
#modify name value
$object->name('foo');
```

principals( )

Use this method to set or retrieve a list of equivalent principals.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is an array of desired principal names in string format.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get principals value
my $principals = $object->principals();

#modify principals value
$object->principals(['foo', 'bar']);
```

NAME

Infoblox::DNS::DDNS::PrincipalCluster::Group - A DDNS Principal Cluster Group object.

DESCRIPTION

The DDNS Principal Cluster Group object represents a set of DDNS Principal Clusters. A single group can be active at any time.

CONSTRUCTOR

```
my $cluster = Infoblox::DNS::DDNS::PrincipalCluster::Group->new(
    name     => $string,                    # Required
    comment  => $string,                    # Optional / Default is undefined
);
```

SESSION METHODS

This section describes all the methods in a Session module that you can apply to a DDNS Principal Cluster Group object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#construct an object
my $object = Infoblox::DNS::DDNS::PrincipalCluster::Group->new(
   name  => 'cluster1',
);

#submit for addition
my $response = $session->add($object);
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

 name    - Optional. A DDNS Principal Cluster Group name in a string format.
 comment - Optional. A DDNS Principal Cluster Group comment.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::DNS::DDNS::PrincipalCluster::Group',
    name   => 'cluster1',
);
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
#Use method to modify the comment.
$object->comment('this is a modified comment');
#Submit modification
my $response = $session->modify($object);
```

Infoblox::Session->remove( )

Use this method to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Example

```
#Get the objects with the same name
my @retrieved_objs = $session->get(
    object => 'Infoblox::DNS::DDNS::PrincipalCluster::Group',
    name   => 'cluster1',
);
#Find the desired object from the retrieved list.
my $desired_cluster = $retrieved_objs[0];
#Submit for removal
my $response = $session->remove($desired_cluster);
```

Infoblox::Session->search( )

Use this method to search for objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key Reference

```
Apply the following attribute to get a specific object:

 name    - Optional. A DDNS Principal Cluster Group name in a string format.
 comment - Optional. A DDNS Principal Cluster Group comment.
```

Example

```
my @retrieved_objs = $session->get(
    object => 'Infoblox::DNS::DDNS::PrincipalCluster::Group',
    name   => 'group1',
);
```

MODULE METHODS

Infoblox::Grid::DNS->ddns_principal_group( )

Use this method to set or retrieve the DDNS Principal Cluster Group. See Infoblox::Grid::DNS->ddns_principal_group() for parameters and return values.

Example

```
#get ddns_principal_group value
my $ddns_principal_group = $object->ddns_principal_group();

#modify ddns_principal_group value
$object->ddns_principal_group($group1);
```

Infoblox::DNS::Zone->ddns_principal_group( )

Use this method to set or retrieve the DDNS Principal Cluster Group. See Infoblox::DNS::Zone->ddns_principal_group() for parameters and return values.

Example

```
#get ddns_principal_group value
my $ddns_principal_group = $object->ddns_principal_group();
```

```
#modify ddns_principal_group value
$object->ddns_principal_group($group1);
```

Infoblox::DNS::View->ddns_principal_group( )

Use this method to set or retrieve the DDNS Principal Cluster Group. See Infoblox::DNS::View->ddns_principal_group() for parameters and return values.

Example

```
#get ddns_principal_group value
my $ddns_principal_group = $object->ddns_principal_group();

#modify ddns_principal_group value
$object->ddns_principal_group($group1);
```

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

clusters( )

Use this method to retrieve a list of equivalent DDNS principal clusters. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is array of an Infoblox::DNS::DDNS::PrincipalCluster objects.

Example

```
#get clusters value
my $clusters = $object->clusters();
```

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The valid value is a comment in string format (UTF-8) with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get comment value
my $comment = $object->comment();

#modify comment value
$object->comment('desired comment');
```

name( )

Use this method to set or retrieve the DDNS Principal Cluster Group name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns 'true' when the modification succeeds, and returns 'false' when the operation

fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#get name value
my $name = $object->name();

#modify name value
$object->name('foo');
```

NAME

Infoblox::DNS::DNSSecKey - DNSSEC key object.

DESCRIPTION

The DNSSEC object contains information about keys available in authoritative zones.

SESSION METHODS

The object does not support any session methods.

METHODS

This section describes all the methods that you can use to set or retrieve the attribute values of the object.

algorithm( )

Use this method to retrieve the public-key encryption algorithm. This is a read-only attribute.

Parameter

None

Returns

The return value is the public-key encryption algorithm in string format.

Example

```
#Get algorithm value
my $value = $dnssec_key->algorithm();
```

next_event_date( )

Use this method to retrieve the next event date. The event date can be a date for the rollover of an ACTIVE key or a PUBLISHED key, or the removal of a ROLLED key. This is a read-only attribute.

Parameter

None

Returns

The date of next event in ISO 8601 extended format (e.g., 2008-10-21T10:56:00Z or 2008-10-21T10:56:00.001Z).

Example

```
#Get next_event_date value
my $value = $dnssec_key->next_event_date();
```

public_key( )

Use this method to retrieve the Base-64 encoding of the public key. This is a read-only attribute.

Parameter

None

Returns

The return value is a Base-64 encoded public key in string format.

Example

```
#Get public_key value
my $value = $dnssec_key->public_key();
```

status( )

Use this method to retrieve key status for the authoritative zone. This is a read-only attribute.

Parameter

None

Returns

The valid return values are "ACTIVE", "PUBLISHED" and "ROLLED".

Example

```
#Get status value
my $value = $dnssec_key->status();
```

tag( )

Use this method to retrieve the key tag for the authoritative zone. This is a read-only attribute.

Parameter

None

Returns

The return value is an integer between 0 and 65535.

Example

```
#Get tag value
my $value = $dnssec_key->tag();
```

type( )

Use this method to retrieve the type of key. This is a read-only attribute.

Parameter

None

Returns

The valid return values are "KSK" and "ZSK".

Example

```
#Get type value
my $value = $dnssec_key->type();
```

NAME

Infoblox::DNS::DNSSecKeyAlgorithm - DNSSEC key algorithm object.

DESCRIPTION

The DNSSEC key algorithm structure provides for configuring algorithms for Key-signing and Zone-signing keys. Multiple algorithms can be used at the same time per Grid or per zone.

CONSTRUCTOR

```
 #Constructor for an DNSSEC key algorithm object
  my $algorithm = Infoblox::DNS::DNSSecKeyAlgorithm->new(
     algorithm => "RSAMD5" | "DSA" | "RSASHA1" | "RSASHA256" | "RSASHA512" ,  #Optional / Default is
undefined
     size      => $num,                                                       #Optional / Default is
undefined
   );
```

MODULE METHODS

The following functions are available to be applied to an DNSSecKeyAlgorithm object.

Infoblox::Grid::DNS->dnssec_ksk_algorithms( )

Use this function to specify a DNSSEC key signing key algorithm at the grid level on the Infoblox appliance. See Infoblox::Grid::DNS->dnssec_ksk_algorithms() for parameters and return values.

Example

```
#Create a DNSSEC key algorithm object.
my $algorithm = Infoblox::DNS::DNSSecKeyAlgorithm->new(
    algorithm => 'RSASHA256',
    size      => 512,
);

#Configure DNSSEC key signing key algorithms on the Infoblox grid object
my $response = $grid->dnssec_ksk_algorithms([$algorithm]);
```

Infoblox::Grid::DNS->dnssec_zsk_algorithms( )

Use this function to specify a DNSSEC zone signing key algorithm at the grid level on the Infoblox appliance. See Infoblox::Grid::DNS->dnssec_zsk_algorithms() for parameters and return values.

Example

```
#Create a DNSSEC key algorithm object.
my $algorithm = Infoblox::DNS::DNSSecKeyAlgorithm->new(
    algorithm => 'RSASHA512',
    size      => 1024,
);

#Configure DNSSEC zone signing key algorithms on the Infoblox grid object
```

```
my $response = $grid->dnssec_zsk_algorithms([$algorithm]);
```

Infoblox::Grid::Member::DNS->dnssec_ksk_algorithms( )

Use this function to specify a DNSSEC key signing key at the member level on the Infoblox appliance. See Infoblox::Grid::Member::DNS->dnssec_ksk_algorithms() for parameters and return values.

Example

```
#Create a DNSSEC key algorithm object.
my $algorithm = Infoblox::DNS::DNSSecKeyAlgorithm->new(
    algorithm => 'RSASHA512',
    size      => 1024,
);

#Configure DNSSEC key signing key algorithms on the Infoblox member object
my $response = $member->dnssec_ksk_algorithms([$algorithm]);
```

Infoblox::Grid::Member::DNS->dnssec_zsk_algorithms( )

Use this function to specify a DNSSEC zone signing key at the member level on the Infoblox appliance. See Infoblox::Grid::Member::DNS->dnssec_zsk_algorithms() for parameters and return values.

Example

```
#Create a DNSSEC key algorithm object.
my $algorithm = Infoblox::DNS::DNSSecKeyAlgorithm->new(
    algorithm => 'RSASHA512',
    size      => 1024,
);

#Configure DNSSEC zone signing key algorithms on the Infoblox member object
my $response = $member->dnssec_zsk_algorithms([$algorithm]);
```

SESSION METHODS

The object does not support any session methods.

METHODS

this section describes all the methods that you can use to set or retrieve the attribute values of the object.

algorithm( )

Use this method to set or retrieve signing key algorithm.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is 'RSAMD5', 'DSA', 'RSASHA1', 'RSASHA256' or 'RSASHA512'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get algorithm value
my $algorithm = $dnssec_key_algorithm->algorithm();
#Modify algorithm value
$dnssec_key_algorithm->algorithm('RSASHA512');
```

size( )

Use this method to set or retrieve signing key size, in bits.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The DNSSEC key-signing key possible size depends on the algorithm. Use the following table to determine the possible values for key sizes:

```
  Algorithm    Key size     Additional restrictions
NSEC
  RSA/MD5      512-4096
  DSA/SHA1     512-1024     Key size must be divisible by 64
  RSA/SHA1     512-4096
  RSA256/SHA2  512-4096
  RSA512/SHA2  1024-4096
NSEC3
  DSA/SHA1     512-1024     Key size must be divisible by 64
  RSA/SHA1     512-4096
  RSA256/SHA2  512-4096
  RSA512/SHA2  1024-4096
```

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get size value
my $size = $dnssec_key_algorithm->size();
#Modify size value
$dnssec_key_algorithm->size(1024);
```

NAME

Infoblox::DNS::DnssecTrustedKey - DNSSEC trusted key object.

DESCRIPTION

For recursively derived signed data, the DNS server can perform validation. In order to be secure, this validation relies on a set of trust anchors. These trust anchors and their associated trusted keys can be specified via the Infoblox::DNS::DnssecTrustedKey objects.

DNSSEC is based on DNS specifications RFC 4033, RFC 4034, and RFC 4035, which provide authentication protocol enhancements to secure DNS transactions.

CONSTRUCTOR

```
 my $dnssec_trusted_key=Infoblox::DNS::DnssecTrustedKey->new(
                    algorithm             =>
"RSAMD5"|"DSA"|"RSASHA1"|"NSEC3DSA"|"NSEC3RSASHA1"|"RSASHA256"|"RSASHA512"|"NSEC3RSASHA256"|"NSEC3RSASHA512"|1|3|5|6|7,
  #Required
                    fqdn                  => $string,                                  #Required
                    key                   => $string,                                  #Required
                    secure_entry_point    => "true"|"false"                            #Optional / Default is "true"
                        );
```

MODULE METHODS

This section describes all the functions that you can apply to a DnssecTrustedKey object.

Infoblox::Grid::DNS->dnssec_trusted_keys( )

Use this function to specify a list of DNSSEC keys for a grid object.

Example

```
      ## Construct the trusted key object. When trying to implement this example replace with the actual public key
     of the signed zone.
      my $dnssec_key = Infoblox::DNS::DnssecTrustedKey->new(
          algorithm => "RSAMD5",
          fqdn => "example.com",
          key  => "Zx1jVJl7C58GT/sc7Q3ucA==",
          secure_entry_point => "false"
      );
      # Configure dnssec_trusted_keys on the grid DNS object
      my $response = $Grid_DNS->dnssec_trusted_keys([$dnssec_key]);
```

Infoblox::Grid::Member::DNS->dnssec_trusted_keys( )

Use this function to specify a list of DNSSEC keys for a grid member object.

Example

```
      ## Construct the trusted key object
      my $dnssec_key = Infoblox::DNS::DnssecTrustedKey->new(
          algorithm => "RSAMD5",
          fqdn => "example.com",
          key  => "Zx1jVJl7C58GT/sc7Q3ucA==",
          secure_entry_point => "false"
      );
      # Configure dnssec_trusted_keys on the grid DNS object
      my $response = $Grid Member DNS->dnssec trusted keys([$dnssec key]);
```

Infoblox::DNS::View->dnssec_trusted_keys( )

Use this function to specify a list of DNSSEC keys for a DNS View object.

Example

```
## Construct the trusted key object
my $dnssec_key = Infoblox::DNS::DnssecTrustedKey->new(
    algorithm => "RSAMD5",
    fqdn => "example.com",
    key  => "Zx1jVJl7C58GT/sc7Q3ucA==",
    secure_entry_point => "false"
);
# Configure dnssec_trusted_keys on the grid DNS object
my $response = $DNS_View->dnssec_trusted_keys([$dnssec_key]);
```

METHODS

algorithm( )

Use this method to set or retrieve a DNSSEC encryption algorithm.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The public-key encryption algorithm. This can be either an integer or mnemonic. The following table shows the correlation between the integers and mnemonics for the algorithms supported by the appliance:

Value	Algorithm	Mnemonic
1	RSA/MD5	RSAMD5
3	DSA	DSA
5	RSA/SHA-1	RSASHA1
6	NSEC3DSA	NSEC3DSA
7	NSEC3RSA/SHA-1	NSEC3RSASHA1

For algorithms not listed above, only the mnemonic representation is supported.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting algorithm
my $algorithm = $dnssec_key->algorithm();
# Modifying algorithm
$dnssec_key->algorithm("DSA");
```

fqdn( )

Use this method to set or retrieve the FQDN of the zone to which the key belongs.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

FQDN of the zone to which the trusted_key pertains, in DNS label order.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting fqdn
my $zone = $dnssec_key->fqdn();
# Modifying algorithm
$dnssec_key->fqdn("zone.example.com");
```

key( )

Use this method to add or retrieve the DNSSEC public key for the zone.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Base-64 encoding of the key.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting key
my $key = $dnssec_key->key();
# Modifying key
$dnssec_key->key("AQPdWbrGbVv1eDhNgRhpJMPonJfA3reyEo82ekwRnjbX7+uBxB11BqL7LAB7/C+eb0vCtI53FwMhkkNkTmA6bI8B");
```

secure_entry_point()

Use this method to set or retrieve the secure entry point value for the field.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Set to "true" to enable the secure entry point, set to "false" to disable it. Default value of this parameter is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting secure_entry_point
my $sep = $dnssec_key->secure_entry_point();
# Modifying secure_entry_point
$dnssec_key->secure_entry_point("false");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add and modify. This sample also includes error handling for the operations.

##Preparation prior to a DnssecTrustedKey object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox  appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DnssecTrustedKey object

```
 my $dnssec_key = Infoblox::DNS::DnssecTrustedKey->new(
    key  => "ZX1jVJl7C58GT/sc7Q3ucA==",
    fqdn => "myzone.example.com",
    algorithm => "RSASHA1"
  );

unless($dnssec_key) {
     die("Construct DnssecTrustedKey failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DnssecTrustedKey object created successfully\n";
```

#Get the member DNS object and add a DnssecTrustedKey object to it

```
my @result_array = $session->get(
    object => "Infoblox::Grid::Member::DNS",
    name   => "infoblox.localdomain"
);

unless (scalar(@result_array) == 0) {
    my $memberdns = $result_array[0];

    if ($memberdns) {

        #Apply changes to the Member object.
```

```
                $memberdns->dnssec_trusted_keys([$dnssec_key])
            or die("modify member failed: ",
                   Infoblox::status_code() . ":" . Infoblox::status_detail());
        print "DnssecTrustedKey added to Member DNS object successfully\n";

  #Update member DNS object through the Infoblox session.
        $session->modify($memberdns)
            or die("modify session failed: ",
                   $session->status_code() . ":" . $session->status_detail());
        print "Member DNS object with DnssecTrustedKey updated to Infoblox device successfully\n";

         #Modify existing DnssecTrustedKey object

        #Modifying the value of the specified object.
        $dnssec_key->fqdn("another.example.com");
        print "Modify DnssecTrustedKey fqdn value\n";

        #Apply changes to the member object.
        $memberdns->transfer_keys([$dnssec_key])
            or die("modify member failed: ",
                   Infoblox::status_code() . ":" . Infoblox::status_detail());
        print "DnssecTrustedKey fqdn updated to Member DNS object successfully\n";

        #Update member DNS object through the Infoblox session.
        $session->modify($memberdns)
            or die("modify session failed: ",
                $session->status_code() . ":" . $session->status_detail());
                print "Member DNS object with DnssecTrustedKey fqdn updated to Infoblox device successfully\n";
             }
         } else {
             print "No member found with the specified name.";
         }

NAME

Infoblox::DNS::FireEyeAlertMap - FireEye Alert Map object

DESCRIPTION

The alert map object is used to configure FireEye alerts to Response Policy Zone rules.

CONSTRUCTOR

```
 my $alertmap = Infoblox::DNS::FireEye::AlertMap->new(
     alert_type => "INFECTION_MATCH" | "WEB_INFECTION" | "MALWARE_OBJECT" | "DOMAIN_MATCH" |
"MALWARE_CALLBACK", # Required
     rpz_rule   => "PASSTHRU" | "NXDOMAIN" | "NODATA" | "SUBSTITUTE" | "NONE", # Required
     lifetime   => $uint, # Required
 );
```

MODULE METHODS

The following functions are available to apply to a FireEye Alert Map object.

Infoblox::DNS::FireEye::RuleMapping->fireeye_alert_mapping( )

Use this function to specify the alert map for this rule mapping. See Infoblox::DNS::FireEye::RuleMapping->fireeye_alert_mapping() for parameters, return values and code samples.

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DNS Member object.

alert_type( )

Use this method to set or retrieve the alert type.

Parameter

The valid value is one of "INFECTION_MATCH", "WEB_INFECTION", "MALWARE_OBJECT", "DOMAIN_MATCH" or "MALWARE_CALLBACK".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get alert_type
my $alert_type = $am->alert_type();
#Modify alert_type
$am->alert_type("INFECTION_MATCH");
```

rpz_rule( )

Use this method to set or retrieve the rpz rule.

Parameter

The valid value is one of "PASSTHRU", "NXDOMAIN", "NODATA", "SUBSTITUTE" or "NONE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get rpz_rule
my $rpz_rule = $am->rpz_rule();
#Modify rpz_rule
$am->rpz_rule("PASSTHRU");
```

lifetime( )

Use this method to set or retrieve the expiration lifetime for this alert type.

Parameter

The valid value is an unsigned integer, which specifies the amount of seconds this alert type will live for. 0 means the alert will never expire.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lifetime
my $lifetime = $am->lifetime();
#Modify lifetime
$am->lifetime(1234);
```

NAME

Infoblox::DNS::FireEyeRuleMapping - FireEye Rule Mapping object

---

DESCRIPTION

The rule map object is used to configure rule mapping for FireEye devices and Response Policy Zones.

CONSTRUCTOR

```
my $rulemapping = Infoblox::DNS::FireEye::Rulemapping->new(
    fireeye_alert_mapping => [$am1, am2, ...], #Optional
    apt_override => "PASSTHRU" | "NXDOMAIN" | "NODATA" | "SUBSTITUTE" | "NOOVERRIDE", #Optional
    substituted_domain_name => $fqdn, #Optional
);
```

MODULE METHODS

The following functions are available to apply to a FireEye Alert Map object.

Infoblox::DNS::Zone->fireeye_rule_mapping( )

Use this function to specify the alert map for this rule mapping. See Infoblox::DNS::Zone->fireeye_rule_mapping() for parameters and return values.

Example

```
my $am1 = Infoblox::DNS::FireEye::AlertMap->new(
                                                alert_type => 'INFECTION_MATCH',
                                                rpz_rule => 'PASSTHRU',
                                                lifetime => 0,
                                               );

unless($am1) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}

my $am2 = Infoblox::DNS::FireEye::AlertMap->new(
                                                alert_type => 'WEB_INFECTION',
                                                rpz_rule => 'NONE',
                                                lifetime => 1234,
                                               );

unless($am2) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}

my $rm = Infoblox::DNS::FireEye::RuleMapping->new(
                                                  fireeye_alert_mapping => [$am1, $am2],
                                                  apt_override => 'SUBSTITUTE',
                                                  substituted_domain_name => 'somedomain.com'
                                                 );
$rpz_zone->rpz_type('FIREEYE');
$rpz_zone->fireeye_rule_mapping($rm);
```

```
my $response = $session->modify($rpz_zone)
unless($response) {
     die("Modify zone failed: ",
           session->status_code() . ":" . session->status_detail());
}
print "Zone modified successfully\n";
```

apt_override( )

Use this method to set or retrieve the APT override.

Parameter

The valid value is one of "PASSTHRU", "NXDOMAIN", "NODATA", "SUBSTITUTE" or "NOOVERRIDE".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get apt_override
my $apt_override = $rm->apt_override();
#Modify apt_override
$rm->apt_override("NOOVERRIDE");
```

fireeye_alert_mapping( )

Use this method to set or retrieve the FireEye alert mapping.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Returns

An array of the Infoblox::DNS::FireEye::AlertMap manpage objects.

Example

```
#Get fireeye_alert_mapping
my $fireeye_alert_mapping = $zone->fireeye_alert_mapping();
#Modify fireeye_alert_mapping
$rm->fireeye_alert_mapping([$am1, $am2]);
```

substituted_domain_name( )

Use this method to set or retrieve the domain name to be substituted, this is applicable only when apt_override is set to "SUBSTITUTE".

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The domain name to use.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get substituted_domain_name
my $substituted_domain_name = $rm->substituted_domain_name();
#Modify substituted_domain_name
$rm->substituted_domain_name("somedomain.com");
```

NAME

Infoblox::DNS::GlueRecordAddr - Infoblox DNS Glue Record Object.

DESCRIPTION

The GlueRecordAddr allows you to specify which interface address the appliance uses to generate the glue record for each view.

CONSTRUCTOR

The Infoblox::DNS::GlueRecordAddr object is automatically generated upon the successful creation of the Infoblox::DNS::View object. It does not require manual construction.

MODULE METHODS

This section describes all the functions that you can apply to a GlueRecordAddr object.

Infoblox::Grid::Member::DNS->glue_record_addresses( )

Use this function to specify a glue record address for a view at the grid member level. See Infoblox::Grid::Member::DNS->glue_record_addresses() for parameters and return values.

Example

```
# Retrieve the list of GlueRecordAddr objects from Member DNS object.
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member::DNS",
    name   => "infoblox.localdomain" );

#select the desired GlueRecordAddr for the view
my $Grid_Member_DNS = $retrieved_objs[0];
my $ref_all_glue_record_addr = $Grid_Member_DNS->glue_record_addresses();
my $glue_record_addr = @$ref_all_glue_record_addr[0];

# Modify Glue Record Address for the view to use NAT address.
$glue_record_addr->glue_record_address("NAT");

#Save modification to Member DNS object.
my $response = $Grid_Member_DNS->glue_record_addresses($ref_all_glue_record_addr);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a GlueRecordAddr object.

attach_empty_recursive_view( )

Use this method to set or retrieve the attach_empty_recursive_view flag of glue record object. If the attach_empty_recursive_view flag is set to "true", then empty view with recursion enabled will be written into the conf file.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the attach_empty_recursive_view flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get attach_empty_recursive_view.
my $attach_empty_recursive_view = $glue_record_addr->attach_empty_recursive_view();
#Modify attach_empty_recursive_view.
$glue_record_addr->attach_empty_recursive_view("true");
```

glue_record_address( )

Use this method to set or retrieve the address the appliance uses to generate the glue record.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

String which specifies the interface address to use. Valid values are "interface", "NAT", or specify an IPv4 or IPv6 address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get glue record address.
my $glue_record_address = $glue_record_addr->glue_record_address();
#Modify glue record address.
$glue_record_addr->glue_record_address("NAT");
```

view( )

Use this method to retrieve the view of this Glue Record object

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get view
my $glue_record_view = $glue_record_addr->view();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as get and modify. This sample also includes error handling for the operations.

#Preparation prior to a DNS GlueRecordAddr object modification

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $session = Infoblox::Session->new(
           master   => "192.168.1.2",
           username => "admin",
           password => "infoblox"
);

unless ($session) {
   die("Construct session failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

```
# Retrieve the list of GlueRecordAddr objects from Member DNS object.
my @retrieved_objs = $session->get(
    object => "Infoblox::Grid::Member::DNS",
    name   => "infoblox.localdomain" );

my $Grid_Member_DNS = $retrieved_objs[0];
unless ($Grid_Member_DNS) {
   die("Retrieve Grid Member DNS object failed: ",
       $session->status_code() . ":" . $session->status_detail());
}
print "Grid Member DNS object retrieve successfully\n";
```

#Modify the Glue Record address

```
my $ref_all_glue_record_addr = $Grid_Member_DNS->glue_record_addresses();

# Select the desired GlueRecordAddr for the view
my $glue_record_addr = @$ref_all_glue_record_addr[0];
unless ($glue_record_addr) {
   die("Glue Record Address not found on Grid Member DNS object: ",
       $session->status_code() . ":" . $session->status_detail());
}
print "Glue Record Address found on Grid Member DNS object\n";

# Modify Glue Record Address for the view to use a custom defined address.
$glue_record_addr->glue_record_address("interface")
    or die("modify glue record failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
print "Glue Record Address modified successfully\n";

# Save modification to Member DNS object.
my $response = $Grid_Member_DNS->glue_record_addresses($ref_all_glue_record_addr);
unless($response) {
    die("Modify glue record on Member DNS failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Glue Record Address updated to Grid Member DNS object successfully\n";

#submit changes to Infoblox appliance
$session->modify($Grid_Member_DNS)
   or die("Modify Member DNS object on Infoblox appliance failed: ",
        Infoblox::status_code() . ":" . Infoblox::status_detail());
print "Grid Member DNS modified on Infoblox appliance successfully\n";

NAME

Infoblox::DNS::Host - DNS Host record object.

DESCRIPTION

A host record defines attributes for a node, such as the name-to-address and address-to-name mapping. This alleviates having to specify an A record and a PTR record separately for the same node. A host can also define aliases and DHCP fixed address nodes. The zone must be created first before adding a host record for the zone.

Note that you must specify only one view for the attribute "views".

CONSTRUCTOR

```
 my $host = Infoblox::DNS::Host->new(
     ipv4addrs               => [$ipv4addr, $ipv4addr, $FixedAddr, ...], #Required
     name                    => $fqdn,                                   #Required
     aliases                 => [$fqdn, $fqdn, ...],                     #Optional / Default is empty
     comment                 => $string,                                 #Optional / Default is undefined
     configure_for_dns       => "true" | "false",                        #Optional / Default "true"
     disable                 => "true" | "false",                                #Optional / Default
"false"
     extattrs                => { $string => $extattr, ... },            #Optional / Default is undefined
     extensible_attributes   => { $string => $string | $num, $string => [ $string | $num, ... ], ... }
#Optional / Default is undefined
     ipv6addrs               => [$ipv6addr, $ipv6addr, ...],             #Optional / Default is empty
```

```
     network_view             => $NetworkView,                          #Optional / Default is "default"
network view
     rrset_order              => "cyclic" | "random" | "fixed",         #Optional / Default "cyclic"
     ttl                      => $num | undef,                              #Optional / Default is
undefined
     views                    => [$View]                                #Optional / Default is "default"
view
     cli_credentials          => [$cli1, ...],                          #Optional
     override_cli_credentials => "true" | "false",                      #Optional / Default is "false"
     device_type              => $string,                               #Optional
     device_vendor            => $string,                               #Optional
     device_location          => $string,                               #Optional
     device_description       => $string,                               #Optional
     allow_telnet             => "true" | "false",                      #Optional / Default is "false"
     ddns_protected           => "true" | "false",                      #Optional / Default is "false"
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to a DNS host record object.

Infoblox::Session->add( )

Use this method to add a host record object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $host = Infoblox::DNS::Host->new(
    name         => "host1.test.com",
    aliases      => ["one.foo.com", "two.foo.com"],
    comment      => "add a host host1.test.com",
    disable      => "true",
    ipv4addrs    => ["4.4.4.4"],
    ipv6addrs    => ["2001::1:2:3:4"],
    newtork_view => $nview,
    ttl          => 3600,
    views        => [$view1],
);

# Submit for addition
my $response = $session->add( $host );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DNS host object:

  name          - Optional. A host name in string format.
  network_view  - Optional. The network view in which the host record is located. By default, all
network views are searched.
  view          - Optional. The DNS view in which the host record is located. By default, all DNS
views are searched. But if you omit this attribute and specify a zone, the appliance searches the
'default' view only.
  zone          - Optional. A zone name in FQDN format.
  comment       - Optional. A comment in string format (regular expression)
  mac           - Optional. A MAC address present in any FixedAddr object in the ipv4addrs member.
  ipv4addr      - Optional. An IP address in string format (regular expression).
  ipv6addr      - Optional. An IPv6 address in string format (regular expression).
  alias         - Optional. An alias of the host in string format (regular expression).
  extattrs      - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
```

Examples

```
my @retrieved_objs = $session->get(
                     object       => "Infoblox::DNS::Host",
                     name         => "host1.test.com",
                     network_view => "default",
                     view         => "default" );

my @retrieved_objs = $session->get(
```

```
                        object                => "Infoblox::DNS::Host",
                        extensible_attributes => { 'Site' => 'Santa Clara' });

    # get all DNS host objects in zone "test.com" of default view
    my @retrieved_objs = $session->get(
                        object       => "Infoblox::DNS::Host",
                        zone         => "test.com",
                        network_view => "default",
                        view         => "default" );
```

Infoblox::Session->modify( )

Use this method to modify a host record object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
    # Use method to modify the comment.
    $host->comment("this is a modified comment");
    # Submit modification
    my $response = $session->modify( $host );
```

Infoblox::Session->remove( )

Use this method to remove a host record object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specific object, first use `get()` or `search()` to retrieve the specific host record object, and then submit this object for removal.

Example

```
    # Get the objects with the same name
    my @retrieved_objs = $session->get(
        object => "Infoblox::DNS::Host",
        name   => "host1.test.com",
        view   => "default" );
    # Find the desired object from the retrieved list.
    my $desired_host = $retrieved_objs[0];
    # Submit for removal
    my $response = $session->remove( $desired_host );
```

Infoblox::Session->search( )

Use this method to search for DNS host record objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
    Apply the following attributes to search for a DNS host record object:

      name          - Optional. A host name in string format (regular expression).
      network_view  - Optional. The network view in which the host record is located. By default, all
    network views are searched.
      view          - Optional. The DNS view in which the host record is located. By default, all DNS
    views are searched. But if you omit this attribute and specify a zone, the appliance searches the
    'default' view only.
      zone          - Optional. A zone name in FQDN format.
      comment       - Optional. A comment in string format (regular expression).
      mac           - Optional. A MAC address present in any FixedAddr object in the ipv4addrs member
    (regular expression).
      ipv4addr      - Optional. An IP address in string format (regular expression).
      ipv6addr      - Optional. An IPv6 address in string format (regular expression).
      alias         - Optional. An alias of the host in string format (regular expression).
      extattrs      - Optional. A hash reference containing extensible attributes.
      extensible_attributes - Optional. A hash reference containing extensible attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Examples

```
    # search for all DNS host objects that match ".test.com" in the default DNS view
    my @retrieved_objs = $session->search(
        object  => "Infoblox::DNS::Host",
        name    => '.*\.test\.com',
        view    => "default",
        comment => ".*modified comment" );

    # search for DNS host objects defining "Santa Clara" for "Site" extensible attribute
```

```
my @retrieved_objs = $session->search(
    object                => "Infoblox::DNS::Host",
    extensible_attributes => { 'Site' => 'Santa Clara' });

# search for all DNS host objects in zone "test.com" of default view
my @retrieved_objs = $session->search(
    object       => "Infoblox::DNS::Host",
    zone         => "test.com",
    network_view => "default",
    view         => "default" );
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a host record.

aliases( )

Use this method to set or retrieve the aliases of the host.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The attribute value can be in unicode format.

Parameter

Array reference with the aliases for the host. The aliases of the host should be in Fully Qualified Domain Name (FQDN) format. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting aliases
my $ref_aliases = $host->aliases();
#Modifying aliases
$host->aliases(["one1.foo.com", "two2.foo.com"]);
```

allow_telnet( )

Use this method to set or retrieve the flag that enables copying SSH credential to TELNET.

Parameter

Specify 'true' to copy SSH credential to TELNET or 'false' to disable it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $host->allow_telnet();
# Modify attribute value
$host->allow_telnet('true');
```

cloud_info( )

Use this method to retrieve cloud API related information for the Infoblox::DNS::Host object.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get cloud_info
```

```
my $cloud_info = $object->cloud_info();
```

comment( )

Use this method to set or retrieve a descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $host->comment();
#Modify comment
$host->comment("Modifying the DNS host comment");
```

configure_for_dns( )

Use this method to set or retrieve the configure_for_dns flag of a DNS host.

When configure_for_dns is false the host will not have parent zone information.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value for this field is true.

Parameter

Specify "true" to set the configure_for_dns flag or "false" to deactivate/unset it. The default value is "true".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get configure_for_dns
my $configure_for_dns = $host->configure_for_dns();
#Modify configure_for_dns
$host->configure_for_dns("false");
```

cli_credentials( )

Use this method to set or retrieve the discovery CLI credentials.

Setting this method to a defined value implicitly sets the override_cli_credentials method to "true". Setting the parameter to undefined causes the appliance to use the grid default and automatically resets the override_cli_credentials attribute to "false".

Note that when cli_credentials is set to a defined value and override_cli_credentials is set to "false", the last operation takes precedence. Thus the sequence $host->cli_credentials([$cli]); $host->override_cli_credentials("false"); will set override_cli_credentials to "false", and the sequence $host->override_cli_credentials("false"); $host->cli_credentials([$cli]); will result in override_cli_credentials="true".

Parameter

Valid value is an array reference that contains Infoblox::Grid::Discovery::CLICredential objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get cli_credentials
my $cli_credentials = $host->cli_credentials();
#Modify cli_credentials
$host->cli_credentials([$cli1, $cli2]);
```

ddns_protected( )

Use this method to set or retrieve the flag that indicates whether DDNS updates for this record are allowed or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to protect record from DDNS updates and 'false' to allow DDNS updates for the specified record.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_protected value
my $ddns_protected = $object->ddns_protected();

#Modify ddns_protected value
$object->ddns_protected('true');
```

device_description( )

Use this method to set or retrieve the description of the discovery device.

Parameter

The device description in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_description
my $device_description = $host->device_description();
#Modify device_description
$host->device_description('example');
```

device_location( )

Use this method to set or retrieve the location of the discovery device.

Parameter

The device location in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_location
my $device_location = $host->device_location();
#Modify device_location
$host->device_location('example');
```

device_type( )

Use this method to set or retrieve the type of the discovery device.

Parameter

The device type in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_type
my $device_type = $host->device_type();
#Modify device_type
$host->device_type('example');
```

device_vendor( )

Use this method to set or retrieve the vendor name of the discovery device.

Parameter

The device vendor name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get device_vendor
my $device_vendor = $host->device_vendor();
#Modify device_vendor
$host->device_vendor('example');
```

disable( )

Use this method to set or retrieve the disable flag of a DNS host.

The host can be disabled instead of removed. You can avoid removing and re-adding a host when a network appliance is repaired or relocated. When the changes to the physical appliance are complete, the host can be simply re-enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value for this field is false.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $host->disable();
#Modify disable
$host->disable("false");
```

dns_aliases( )

Use this method to retrieve the aliases, in punycode format, of the host. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $host->dns_aliases();
```

dns_name( )

Use this method to retrieve the host name in punycode format. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $host->dns_name();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DNS Host object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $host->extattrs();
#Modify extattrs
$host->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DNS Host object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $host->extensible_attributes();
#Modify extensible attributes
$host->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

ipv4addrs( )

Use this method to set or retrieve the IPv4 addresses of the host.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains defined Infoblox::DHCP::FixedAddr objects or IPv4 addresses.

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

If the Infoblox library is loaded with the :hostaddress option, the valid value is an array reference that contains Infoblox::DHCP::HostAddr objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Gett ipv4addrs
my $ref_ipv4addr = $host->ipv4addrs();
#Modify ipv4addrs
$host->ipv4addrs([$fixedaddr, "2.2.2.2"]); #$fixedaddr is an Infoblox::DHCP::FixedAddr object
```

ipv6addrs( )

Use this method to set or retrieve the IPv6 addresses of the host.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid value is an array reference that contains IPv6 addresses in string format.

An IPv6 address is a string consisting of eight groups of four hexadecimal digits, where each group is separated by a colon (:) (example: 2001:0db8:85a3:0000:0000:8a2e:0370:7334). Various shortcuts exist to shorten the string representation of an IPv6 address, such as omitting the leading zeros of each group and replacing one or any number of consecutive groups of 0 value with two colons(::). i.e. The previous example can be written as 2001:db8:85a3::8a2e:370:7334.

When creating an Infoblox::DNS::Host object, setting this method to [] is not supported. If the Infoblox::DNS::Host object does not have associated IPv6 addresses, simply do not pass the ipv6addrs attribute to the constructor. If [] is set and the Host object is submitted for addition, the following error will be reported: "A host record requires at least one IP address." Setting the method to [] is supported for modify requests.

If the Infoblox library is loaded with the :hostaddress option, the valid value is an array reference that contains Infoblox::DHCP::IPv6HostAddr objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Gett ipv6addrs
my $ref_ipv6addr = $host->ipv6addrs();
#Modify ipv6addrs
$host->ipv6addrs(["2001::1", "2002::1:2:3:4"]);
```

last_queried( )

Use this method to retrieve the time when the associated record was last queried. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_queried
my $last_queried = $host->last_queried();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $host->ms_ad_user_data();
```

name( )

Use this method to set or retrieve the host name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The attribute value can be in unicode format.

Parameter

Host name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: abc.com). A host name can have a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $host->name();
#Modify name
$host-> name("host2.test.com");
```

network_view( )

Use this method to set or retrieve the network view of the DNS host.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" network view, which means the DNS host is in the default network view.

Parameter

Valid value is a defined Infoblox::DHCP::View object. The default network view value is the system-defined default network view object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get network view
my $nview = $host->network_view();
#Modify network view, with an Infoblox::DHCP::View object
$host->network_view($nview);
```

override_cli_credentials( )

The override_cli_credentials attribute controls whether the cli_credentials value in the object is used, instead of the grid default.

The override_cli_credentials attribute can be specified explicitly. It is also set implicitly when cli_credentials is set to a defined value.

Parameter

Specify "true" to set the override_cli_credentials flag or "false" to deactivate/unset it. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get attribute value
my $value = $host->override_cli_credentials();
# Modify attribute value
$host->override_cli_credentials('true');
```

rrset_order( )

Use this method to set or retrieve the rrset_order value. The value of this parameters specifies the order in which resource record sets are

returned.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The possible values of the parameter are "cyclic", "random" and "fixed". The default value of this parameter is "cyclic".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get rrset_order
my $order = $host->rrset_order()
# Set fixed RR set order
$host->rrset_order("fixed");
```

ttl( )

Use this method to set or retrieve the Time to Live (TTL) value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is undefined which indicates that the record inherits the TTL value of the zone.

Specify a TTL value to override the TTL value at the zone level.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration in seconds that the record is cached. Zero indicates that the record should not be cached. The default value is undefined.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ttl
my $ttl = $host->ttl();
#Modify ttl
$host->ttl(1800);
#Un-override ttl
$host->ttl(undef);
```

views( )

Use this method to set or retrieve the view of the DNS host.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" view, which means the DNS host is located under the default view.

Parameter

Array reference of defined Infoblox::DNS::View objects. The default view value is "default".

Note that the array size must be 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get views
my $ref_views = $host->views();
#Modify views, list of Infoblox::DNS::View objects
$host->views([$view1]);
```

zone( )

Use this method to retrieve the zone name of a DNS host object. This method is read-only and cannot be set.

Parameter

None

Returns

Returns the attribute value.

Example

```
# Get zone
my $zone = $host->zone();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to a Host record object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DNS host record insertion

```
#PROGRAM STARTS: Include all the modules that will be used

use strict;
use Infoblox;

#Create a session to the Infoblox Appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2", #appliance host ip
    username => "admin",     #appliance user login
    password => "infoblox"   #appliance password
);

unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}

#Create the zone prior to an host insertion
my $zone = Infoblox::DNS::Zone->new(name => "test.com");

unless ($zone) {
   die("Construct zone failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}

print "Zone object created successfully\n";

#Verify if the zone exists
my $object = $session->get(object => "Infoblox::DNS::Zone",
                           name => "test.com");
unless ($object) {
   print "Zone does not exist on server, safe to add the zone\n";
   $session->add($zone)
      or die("Add zone failed: ",
             $session->status_code() . ":" . $session->status_detail());
}
print "Zone added successfully\n";
```

#Create a DNS host record

```
#Construct a DNS host object

my $host = Infoblox::DNS::Host->new(
    name         => "host1.test.com",
    aliases      => ["one.foo.com", "two.foo.com"],
    comment      => "add a host host1.test.com",
    disable      => "true",
    ipv4addrs    => ["4.4.4.4"],
    ipv6addrs    => ["2001::4:4:4:4"],
    ttl          => 3600,
);

unless ($host) {
   die("Construct DNS host record failed: ",
```

```
        Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DNS host object created successfully\n";

#Add the DNS host record object to Infoblox appliance through a session
$session->add($host)

    or die("Add host record failed: ",
           $session->status_code() . ":" . $session->status_detail());
     print "DNS host object added to server successfully\n";
```

#Search for a specific DNS host record

```
#Search host record host1.test.com
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::Host",
    name   => 'host1\.test\.com'
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search host record failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search DNS host object found at least 1 matching entry\n";

#Search all host records that start with "add" in the comment
my @retrieved_objs = $session->search(
    object  => "Infoblox::DNS::Host",
    comment => "add.*",
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search host record failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search DNS host object using regexp in comment field found at least 1 matching entry\n";

#Search all host records that start with "host1" in the zone
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::Host",
    name   => 'host1.*\.com',
 );
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search host record failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search DNS host object using regexp in name field found at least 1 matching entry\n";
```

#Get and modify a DNS host record

```
#Get host record through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DNS::Host",
    name   => "host1.test.com"
);
my $object = $retrieved_objs[0];

unless ($object) {
    die("Get host record failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

#Modify one of the attributes of the specified host record
$object->comment("This is the modified comment");

#Applying the changes
$session->modify($object)
    or die("Modify host record failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "DNS host object modified successfully \n";
```

#Remove a DNS host record.

```
#Get host record through the session
my @retrieved_objs = $session->get(
    object => "Infoblox::DNS::Host",
```

```
    name   => "host1.test.com"
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Get host record failed: ",
        $session->status_code() . ":" . $session->status_detail());
}

print "Get DNS host object successfull\n";

#Submit the object for removal

$session->remove($object)
    or die("Remove host record failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "DNS host object removed successfully \n";

NAME

Infoblox::DNS::Member - DNS Member object

DESCRIPTION

A grid member is part of a grid which is a group of two or more Infoblox appliances that share sections of a common, distributed, built-in database. A grid member inherits its settings from the grid. A member is a single Infoblox appliance or an HA pair that provides DNS services seamlessly across an entire network.

CONSTRUCTOR

```
my $member = Infoblox::DNS::Member->new(
    ipv4addr       => $ipv4addr,        #Required if $ipv6addr is not present
    ipv6addr       => $ipv6addr,        #Required if $ipv4addr is not present
    grid_replicate => "true" | "false", #Optional / Default is "true"
    lead           => "true" | "false", #Optional / Default is "false"
    name           => $fqdn,            #Optional / Default is  hostname of the matching ipv4addr
    stealth        => "true" | "false"  #Optional / Default is "false"
    preferred_primaries          => [$pp1, $pp2, ...], #Optional / Default is undefined
    override_preferred_primaries => "true" | "false"   #Optional / Default is "false"
    forward_to          => [$ns1, $ns2, ...],  #Optional
    forwarders_only     => "true" | "false"    #Optional / Default is "false"
    override_forwarders => "true" | "false"    #Optional / Default is "false"
);
```

MODULE METHODS

The following functions are available to apply to an DNS Member object.

Infoblox::DNS::Zone->multiple_primaries( )

Use this function to specify primary members to a zone. See Infoblox::DNS::Zone->multiple_primaries() for parameters and return values.

Example

```
my $member1 = Infoblox::DNS::Member->new(
    name           => "localhost.localdomain",
    ipv4addr       => "192.168.1.2",
    stealth        => "false",
```

```
    lead           => "false",
    grid_replicate => "false"
);

unless($member1) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create the Zone object with this member
my $firstzone = Infoblox::DNS::Zone->new(
    name        => "infoblox.com",
    multiple_primaries => [$member1],
);

my $response = $session->add($firstzone)
unless($response) {
     die("Add zone failed: ",
           session->status_code() . ":" . session->status_detail());
}
print "DNS member object added to the zone successfully\n";
```

Infoblox::DNS::Zone->secondary( )

Use this function to specify secondary member to a zone. See Infoblox::DNS::Zone->secondary() for parameters and return values.

Example

```
my $member1 = Infoblox::DNS::Member->new(
    name           => "localhost.localdomain",
    ipv4addr       => "192.168.1.2",
    stealth        => "false",
    lead           => "false",
    grid_replicate => "false"
);

unless($member1) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

my $member2 = Infoblox::DNS::Member->new(
    name           => "localhost1.localdomain",
    ipv4addr       => "192.168.1.3",
    stealth        => "false",
    lead           => "false",
    grid_replicate => "false"
);

unless($member2) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

#Create the Zone object with this member
my $firstzone = Infoblox::DNS::Zone->new(
    name        => "infoblox.com",
    multiple_primaries => [$member1],
    secondaries => [ $member2 ] ,
);

my $response = $session->add($firstzone)
unless($response) {
     die("Add zone failed: ",
           session->status_code() . ":" . session->status_detail());
}

print "DNS member object added to the zone successfully\n";
```

Infoblox::Grid::DNS::Nsgroup->multiple_primaries( )

Use this function to specify primary members to a NS group. See Infoblox::Grid::DNS::Nsgroup->multiple_primaries() for parameters and

return values.

Example

```
my $member1 = Infoblox::DNS::Member->new(
    name           => "localhost.localdomain",
    ipv4addr       => "192.168.1.2",
    stealth        => "false",
    lead           => "false",
    grid_replicate => "false"
);

unless($member1) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

my $nsgroup1 = Infoblox::Grid::DNS::Nsgroup->new (
   name      => "ns_group1",
   multiple_primaries => [$member1]
);
```

Infoblox::Grid::DNS::Nsgroup->secondary( )

Use this function to specify secondary member to a NS group. See Infoblox::Grid::DNS::Nsgroup->secondary() for parameters and return values.

Example

```
my $member1 = Infoblox::DNS::Member->new(
    name           => "localhost.localdomain",
    ipv4addr       => "192.168.1.2",
    stealth        => "false",
    lead           => "false",
    grid_replicate => "false"
);

unless($member1) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

my $member2 = Infoblox::DNS::Member->new(
    name           => "localhost1.localdomain",
    ipv4addr       => "192.168.1.3",
    stealth        => "false",
    lead           => "false",
    grid_replicate => "false"
);

unless($member2) {
     die("Construct member failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

my $nsgroup1 = Infoblox::Grid::DNS::Nsgroup->new (
   name        => "ns_group1",
   multiple_primaries => [$member1],
   secondaries => [ $member2 ],
);
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DNS Member object.

forward_to( )

Use this method to set or retrieve a list of DNS forwarders. You can use this attribute only for DNS members in forward-mapping zones.

Parameter

The valid value is an array reference that contains Infoblox::DNS::Nameserver objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get forward_to
my $forward_to = $member->forward_to();
#Modify forward_to
my $nameserver = Infoblox::DNS::Nameserver->new(
        name     => "ns1.forwd.com",
        ipv4addr => "11.11.11.11",
   );

$zone->forward_to([$nameserver]);
```

forwarders_only( )

Use this method to set the forwarders_only flag. You can use this attribute only for DNS members in forward-mapping zones.

Parameter

Specify "true" to use only DNS forwarders or "false" to disable it. The default value is 'false'.

The server writes 'forward only' into the DNS configuration file for the DNS member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get forwarders_only
my $forwarders_only = $member->forwarders_only();
#Modify forwarders_only
$member->forwarders_only("true");
```

override_forwarders( )

Use this method to set the override_forwarders flag. You can use this attribute only for DNS members in forward-mapping zones.

Parameter

Specify "true" to override DNS forwarders or "false" to use zone default DNS forwarders. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get override_forwarders
my $override_forwarders = $member->override_forwarders();
#Modify override_forwarders
$member->override_forwarders("true");
```

grid_replicate( )

Use this method to set or retrieve the grid_replicate flag, which indicates whether grid members that are primary and secondary servers use database replication or zone transfers for zone updates.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to use ID grid replication or "false" to use DNS zone transfers.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get grid replicate
my $grid_replicate = $member->grid_replicate();
#Modify grid replicate
$member->grid_replicate("true");
```

ipv4addr( )

Use this method to set or retrieve the IPv4 address of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IPv4 address (32 bits) of the member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4Addr
my $ipv4Addr = $member->ipv4Addr();
#Modify ipv4Addr
$member->ipv4Addr("192.168.1.3");
```

ipv6addr( )

Use this method to set or retrieve the IPv6 address if available. Required only when ipv4 is not specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight groups of four hexadecimal digits separated by colons (example: 12ab:0000:0000:0123:4567:89ab:0000:cdef).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting ipv6addr
my $ipv6addr = $member->ipv6addr();
# Modifying ipv6addr
$member->ipv6addr("12ab::345");
```

lead( )

Use this method to set or retrieve the "lead" flag.

When a primary server is external to a grid whose members are secondary servers, you can designate one member as a lead secondary. The primary server sends zone transfers to the lead secondary, which distributes the zone data to the other secondary servers in the grid using zone transfers (not the ID grid data replication mechanism).

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set lead flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get lead
```

```
my $lead = $member->lead();
#Modify lead
$member->lead("true");
```

ms_parent_delegated( )

Use this method to retrieve the ms_parent_delegated flag. If the zone is a delegation and the primary server of the parent zone is a Microsoft (r) server, this flag is set to "true" if the FQDN and IP address in the delegation zone's NS record matches the FQDN and IP address of its authoritative name server.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get ms_parent_delegated
my $ms_parent_delegated = $member->ms_parent_delegated();
```

name( )

Use this method to set or retrieve the name of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

A name in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the host name followed by the domain name (example: host.domain.com). A host name can have a maximum of 256 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $member->name();
#Modify name
$member->name("dns.infoblox.com");
```

override_preferred_primaries( )

Use this method to set or retrieve the override_preferred_primaries attribute that controls whether the preferred_primaries method values of the member are used.

Parameter

Set the parameter to "true" to use preferred_primaries method values. Set the parameter to "false", and a primary preference list is determined automatically. The default value is "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $value = $member->override_preferred_primaries();
# Modify the attribute value
$member->override_preferred_primaries("false");
```

preferred_primaries( )

Use this method to set or retrieve a primary preference list for the member.

Parameter

A reference to an array of Grid member names only or Infoblox::DNS::Nameserver objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
$value = $member->preferred_primaries();
# Modify the attribute value
$member->preferred_primaries(['test.com', 'example.com']);
$member->preferred_primaries([$nameserver1, $nameserver2]);
```

stealth( )

Use this method to set or retrieve the "stealth" flag, which indicates whether this member is in stealth mode. When a member is in stealth mode, its NS record is hidden from DNS queries; it does not respond to queries from resolvers and other name servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the stealth flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get stealth
my $stealth = $member->stealth();
#Modify stealth
$member->stealth("true");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DNS Member object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance

my $host_ip   = "192.168.1.2";
my $host_name = "infoblox.localdomain";

my $session = Infoblox::Session->new(
               master   => $host_ip, #appliance host ip
               username => "admin",       #appliance user login
               password => "infoblox"     #appliance password
);

unless ($session) {
       die("Construct session failed: ",
               Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a DNS Member object

```
my $member1 = Infoblox::DNS::Member->new(
    name           => $host_name,
    ipv4addr       => $host_ip,
    stealth        => "false",
    lead           => "false",
    grid_replicate => "false"
);

unless($member1) {
```

```
      die("Construct member failed: ",
            Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Member object created successfully\n";

my $default_view = Infoblox::DNS::View->new(name => "default");

#Create the Zone object with this member
my $firstzone = Infoblox::DNS::Zone->new(
    name         => "infoblox.com",
    views        => [$default_view],
    email        => "admin\@infoblox.com",
    comment      => "add a zone infoblox.com",
    multiple_primaries => [$member1],
);

unless($firstzone) {
            die("Construct Zone object failed: ",
                  Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Zone object created successfully\n";

#Add the Zone object into the Infoblox appliance through a session
$session->add($firstzone)
     or die("Add Zone object failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "DNS member object added to the zone successfully\n";

#Modify a DNS member

my @result = $session->search(object => "Infoblox::DNS::Zone",
                              name   => "infoblox.com");

 unless (scalar(@result) == 0) {
     $firstzone = $result[0];

     if ($firstzone) {

          #modify grid replicate value of member
          $member1->grid_replicate("true");

          #update zone
          $firstzone->multiple_primaries([$member1]);

          #update session
          $session->modify($firstzone)
                 or die("Modify zone object failed: ",
                        $session->status_code() . ":" . $session->status_detail());
          print "DNS member object updated and added to the zone successfully\n";
                }
            } else {
                print "No zone found with the specified name";
            }

####PROGRAM ENDS####
```

NAME

Infoblox::DNS::Member::SoaMname - a per-master SOA MNAME information.

DESCRIPTION

The object contains a per-master SOA MNAME Information.

CONSTRUCTOR

```
my $soa_mname = Infoblox::DNS::Member::SoaMname->new(
   grid_member => $string,       # Required if ms_server is not specified
   ms_server   => $string,       # Required if grid_member is not specified
   mname       => $string,       # Optional
);
```

You cannot set both grid_member and ms_server attributes at the same time.

SESSION METHODS

The object doesn't support any session methods.

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the object.

dns_mname( )

Use this method to retrieve the master's SOA MNAME in punycode format. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $soa_mname->dns_mname();
```

grid_member( )

Use this method to set or retrieve the primary server name for the zone.

Parameter

The primary server name in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $attr = $soa_mname->grid_member();
# Modify the attribute value
$soa_mname->grid_member('member.com');
```

mname( )

Use this method to set or retrieve the master's SOA MNAME.

Parameter

The master's SOA MNAME in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $attr = $soa_mname->mname();
# Modify the attribute value
$soa_mname->mname('dummy-mname.com');
```

ms_server( )

Use this method to set or retrieve the IPv4 address or FQDN of the Microsoft (r) Server for the zone.

Parameter

Valid value is an IPv4 address (32 bits) or FQDN of the Microsoft (r) Server.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Get the attribute value
my $attr = $soa_mname->ms_server();
# Modify the attribute value
$soa_mname->ms_server('10.0.0.1');
```

NAME

Infoblox::DNS::Member::SoaSerial - a per-master SOA serial information.

DESCRIPTION

The object contains a per-master SOA serial information.

CONSTRUCTOR

The object cannot be created because all object attributes are read-only.

SESSION METHODS

The object doesn't support any session methods.

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of the object.

grid_member( )

Use this method to retrieve the primary server name for the zone. This is a read-only attribute.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
# Get the attribute value
my $attr = $soa_serial->grid_member();
```

serial( )

Use this method to retrieve the SOA serial number. This is a read-only attribute.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
# Get the attribute value
my $attr = $soa_serial->serial();
```

ms_server

Use this method to retrieve the IPv4 address or FQDN of the Microsoft (r) Server for the zone. This is a read-only attribute.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
# Get the attribute value
my $attr = $soa_serial->ms_server();
```

NAME

Infoblox::DNS::MSServer - Microsoft (r) DNS Server object

DESCRIPTION

A Microsoft DNS Server object is a Windows-based server that is running the DNS service and is synchronized with an Infoblox grid. As such, the Microsoft DNS server shares its DNS data with the Infoblox DNS servers in a grid.

CONSTRUCTOR

```
my $msserver = Infoblox::DNS::MSServer->new(
    address        => $string,           #Required
    ipv4addr       => $string,           #Required
    name           => $string,           #Required
    stealth        => "true" | "false",  #Optional
);
```

MODULE METHODS

The following functions can be applied to a Microsoft DNS Server object.

Infoblox::DNS::Zone->multiple_primaries( )

Use any of these functions to assign a Microsoft DNS server as the primary server of a zone. See Infoblox::DNS::Zone->multiple_primaries() for parameters and return values.

Example

```
my $msserver1 = Infoblox::DNS::MSServer->new(
    address        => "10.0.0.1",
    ipv4addr       => "10.0.0.1",
    name           => "hostname.com",
);

unless($msserver1) {
     die("Construct msserver failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Msserver object created successfully\n";

#Create the Zone object with this Microsoft DNS server
my $firstzone = Infoblox::DNS::Zone->new(
    name        => "infoblox.com",
    multiple_primaries => [$msserver1],
);

my $response = $session->add($firstzone)
unless($response) {
     die("Add zone failed: ",
```

```
            session->status_code() . ":" . session->status_detail());
}
print "DNS MS Server object added to the zone successfully\n";
```

Infoblox::DNS::Zone->secondaries( )

Use this function to specify an Microsoft DNS server as the secondary server to a zone. See Infoblox::DNS::Zone->secondaries() for parameters and return values.

Example

```
my $msserver1 = Infoblox::DNS::MSServer->new(
    address        => "10.0.0.1",
    ipv4addr       => "10.0.0.1",
    name           => "hostname.com",
);

unless($msserver1) {
     die("Construct msserver failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Msserver object created successfully\n";

#Create the Zone object with this member
my $firstzone = Infoblox::DNS::Zone->new(
    name        => "infoblox.com",
    multiple_primaries => [$member1],
    secondaries => [ $msserver2 ] ,
);

my $response = $session->add($firstzone)
unless($response) {
     die("Add zone failed: ",
           session->status_code() . ":" . session->status_detail());
}

print "DNS MS server member object added to the zone successfully\n";
```

Infoblox::DNS::Zone->stub_members( )

Use this function to assign a Microsoft DNS server to a stub zone. See Infoblox::DNS::Zone->stub_members() for parameters and return values.

Example

```
my $msserver1 = Infoblox::DNS::MSServer->new(
    address        => "10.0.0.1",
    ipv4addr       => "10.0.0.1",
    name           => "hostname.com",
);

unless($msserver1) {
     die("Construct msserver failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Msserver object created successfully\n";

#Create the Zone object with this member
my $firstzone = Infoblox::DNS::Zone->new(
    name        => "infoblox.com",
    stub_members => [ $msserver2 ] ,
);

my $response = $session->add($firstzone)
unless($response) {
     die("Add zone failed: ",
           session->status_code() . ":" . session->status_detail());
}

print "DNS MS server member object added to the zone successfully\n";
```

METHODS

This section describes all the methods that you can use to set and retrieve the attribute values of a DNS Member object.

address( )

Use this method to set or retrieve the IPv4 address or FQDN of the member.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IPv4 address (32 bits) or FQDN of the member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get address
my $address = $member->address();
#Modify address
$member->address("192.168.1.3");
```

ipv4addr( )

Use this method to set or retrieve the member IPv4 address that is published in the glue A record when setting this Microsoft DNS server as a name server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

IPv4 address (32 bits) of the member.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $member->ipv4addr();
#Modify ipv4addr
$member->ipv4addr("192.168.1.3");
```

ms_parent_delegated( )

Use this method to retrieve the ms_parent_delegated flag. If the zone is a delegation and the primary server of the parent zone is a Microsoft server, this flag is set to "true" if the FQDN and IP address in the delegation zone's NS record matches the FQDN and IP address of its authoritative name server.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get ms_parent_delegated
my $ms_parent_delegated = $member->ms_parent_delegated();
```

name( )

Use this method to set or retrieve the member FQDN that is used when setting this Microsoft DNS server as a name server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The member's FQDN.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $member->name();
#Modify name
$member->name("hostname.com");
```

stealth( )

Use this method to set or retrieve the "stealth" flag, which indicates whether this name server is in stealth or normal mode.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify "true" to set the stealth flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get stealth
my $stealth = $member->stealth();
#Modify stealth
$member->stealth("true");
```

NAME

Infoblox::DNS::Nameserver - DNS Nameserver object

DESCRIPTION

Manipulates a Nameserver object that contains information about the domain name space.

CONSTRUCTOR

```
 my $nameserver = Infoblox::DNS::Nameserver->new(
     ipv4addr  => $ipv4addr,            #Required if $ipv6addr is not present
     ipv6addr  => $ipv6addr,            #Required if $ipv4addr is not present
     name      => $fqdn,                #Required if this name server is not used to represent an external
DDNS server
     ddns_zone => $string,              #Required if this name server is used to represent an external DDNS
server
     gss_tsig_domain  => $string,       #Optional / Default is undefined
     gss_tsig_dns_principal => $string, #Optional / Default is undefined
     stealth   => "true" | "false",     #Optional / Default is "false"
     TSIGkey   => $string | ":2xCOMPAT" #Optional / Default is undefined
     TSIGname  => $string,              #Optional / Default is undefined
     TSIGalgorithm => "HMAC-MD5" | "HMAC-SHA256" ,  #Optional / Default is "HMAC-MD5"
 );
```

MODULE METHODS

The following functions are available to apply to a nameserver object.

Infoblox::DHCP::View->external_ddns_primaries( )

Use this function to specify a nameserver to send DDNS updates to at the network view level.

Example

```
      #Construct an object
        my $nameserver = Infoblox::DNS::Nameserver->new(
          ipv4addr  => "1.2.3.4",
```

```
    TSIGname  => "tsig_name",
    TSIGkey   => "ZX1jVJl7C58GT/sc7Q3uca==",
    ddns_zone => "zone1"
);

#Construct an object
  my $nameserver1 = Infoblox::DNS::Nameserver->new(
    ipv4addr  => "1.2.3.5",
    TSIGname  => "tsig_name",
    TSIGkey   => "ZX1jVJl7C58GT/sc7Q3uca==",
    ddns_zone => "zone2"
);

# Configure Nameserver
my $response = $View->external_ddns_primaries([$nameserver,$nameserver1]);
```

Infoblox::DNS::Zone->delegate_to( )

Use this function to specify a nameserver at the zone level.

Example

```
#Construct an object
  my $nameserver = Infoblox::DNS::Nameserver->new(
    name      => "ns1.test.com",
    ipv4addr  => "4.4.7.7",
);

# Configure Nameserver
my $response = $Zone->delegate_to([$nameserver]);
```

Infoblox::DNS::Zone->forward_to( )

Use this function to specify a nameserver at the zone level.

Example

```
#Construct an object
  my $nameserver = Infoblox::DNS::Nameserver->new(
    name      => "ns2.test.com",
    ipv4addr  => "4.4.6.6",
);

# Configure Nameserver
my $response = $Zone->forward_to([$nameserver]);
```

Infoblox::DNS::Zone->secondaries( )

Use this function to specify a nameserver at the zone level.

Example

```
#Construct an object
  my $nameserver = Infoblox::DNS::Nameserver->new(
    name      => "ns3.test.com",
    ipv4addr  => "4.5.6.4",
    stealth   => "false",
    TSIGname  => "tsig_name",
    TSIGkey   => "ZX1jVJl7C58GT/sc7Q3uca==",
);

#Construct an object
  my $nameserver1 = Infoblox::DNS::Nameserver->new(
    name      => "ns4.test.com",
    ipv6addr  => "2009::546",
    stealth   => "false",
    TSIGname  => "tsig_name",
    TSIGkey   => "ZX1jVJl7C58GT/sc7Q3uca==",
);

# Configure Nameserver
my $response = $Zone->secondaries([$nameserver,$nameserver1]);
```

Infoblox::DNS::Zone->multiple_primaries( )

Use this function to specify nameservers at the zone level.

Example

```
#Construct an object
  my $nameserver = Infoblox::DNS::Nameserver->new(
    name      => "ns4.test.com",
    ipv4addr  => "4.4.5.6",
    stealth   => "false",
    TSIGname  => "tsig_name",
    TSIGkey   => "ZX1jVJl7C58GT/sc7Q3uca==",
);

#Construct an object
  my $nameserver1 = Infoblox::DNS::Nameserver->new(
    name      => "nsv6.test.com",
    ipv6addr  => "2004::223",
    stealth   => "false",
    TSIGname  => "tsig_name",
    TSIGkey   => "ZX1jVJl7C58GT/sc7Q3uca==",
);

# Configure Nameserver
my $response = $Zone->multiple_primaries([$nameserver,$nameserver1]);
```

Infoblox::Grid::Member->prefer_resolver( )

Use this function to specify a nameserver at the grid member level.

Example

```
#Construct an object
  my $nameserver = Infoblox::DNS::Nameserver->new(
    ipv4addr  => "10.7.5.6",
);

# Configure Nameserver
my $response = $grid_member_object->prefer_resolver([$nameserver]);
```

Infoblox::Grid::Member->alternate_resolver( )

Use this function to specify a nameserver at the grid member level.

Example

```
#Construct an object
  my $nameserver = Infoblox::DNS::Nameserver->new(
    ipv4addr  => "10.10.5.6",
);

# Configure Nameserver
my $response = $grid_member_object->alternate_resolver([$nameserver]);
```

Infoblox::Grid::DNS::Nsgroup->multiple_primaries( )

Use this function to specify nameservers at the grid DNS level.

Example

```
#Construct an object
  my $nameserver = Infoblox::DNS::Nameserver->new(
    name      => "ns5.test.com",
    ipv4addr  => "10.10.5.6",
    stealth   => "false",
    TSIGname  => "tsig_name",
    TSIGkey   => "Zx1JVjl7C58gT/sc7Q3uca==",
);

# Configure Nameserver
my $response = $grid_member_object->multiple_primaries([$nameserver]);
```

Infoblox::Grid::DNS::Nsgroup->secondaries( )

Use this function to specify a nameserver at the grid DNS level.

Example

```
#Construct an object
  my $nameserver = Infoblox::DNS::Nameserver->new(
```

```
        name      => "ns5.test.com",
        ipv4addr  => "10.10.5.6",
        stealth   => "false",
        TSIGname  => "tsig_name",
        TSIGkey   => "Zx1JVjl7C58gT/sc7Q3uca==",
    );

    # Configure Nameserver
    my $response = $grid_member_object->secondaries([$nameserver]);
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of a Nameserver object.

ddns_zone( )

Use this method to set or retrieve the zone name served by the name server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired ddns_zone for the name server in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    # Getting ddns_zone
    my $ddns_zone = $nameserver->ddns_zone();
    # Modifying ddns_zone
    $nameserver->ddns_zone("zone2");
```

gss_tsig_domain( )

Use this method to set or retrieve the domain in which GSS-TSIG for dynamic updates is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired domain name in string format with a maximum of 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
    # Getting gss_tsig_domain
    my $gss_tsig_domain = $nameserver->gss_tsig_domain();
    # Modifying gss_tsig_domain
    $nameserver->gss_tsig_domain("mydomain");
```

gss_tsig_dns_principal( )

Use this method to set or retrieve the principal name in which GSS-TSIG for dynamic updates is enabled.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired principal name in string format with a maximum of 1023 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting gss_tsig_dns_principal
my $gss_tsig_dns_principal = $nameserver->gss_tsig_dns_principal();
# Modifying gss_tsig_dns_principal
$nameserver->gss_tsig_dns_principal("local1/a.localhost@LOCAL");
```

ipv4addr( )

Use this method to set or retrieve the IPv4 address. Required only when ipv6 is not specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192.168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting ipv4addr
my $ipv4addr = $nameserver->ipv4addr();
# Modifying ipv4addr
$nameserver->ipv4addr("10.0.0.3");
```

ipv6addr( )

Use this method to set or retrieve the IPv6 address. Required only when ipv4 is not specified.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight groups of four hexadecimal digits separated by colons (example: 12ab:0000:0000:0123:4567:89ab:0000:cdef).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting ipv6addr
my $ipv6addr = $nameserver->ipv6addr();
# Modifying ipv6addr
$nameserver->ipv6addr("12ab::345");
```

ms_parent_delegated( )

Use this method to retrieve the ms_parent_delegated flag. If the zone is a delegation and the primary server of the parent zone is a Microsoft (r) server, this flag is set to "true" if the FQDN and IP address in the delegation zone's NS record matches the FQDN and IP address of its authoritative name server.

Parameter

None.

Returns

The method returns the attribute value.

Example

```
#Get ms_parent_delegated
my $ms_parent_delegated = $member->ms_parent_delegated();
```

name( )

Use this method to set or retrieve a resolvable domain name for the server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name for the name server in FQDN format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails. If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting name
my $name = $nameserver->name();
# Modifying name
$nameserver->name("ns2.domain.com");
```

stealth( )

Use this method to make the name server stealth or not. When the attribute stealth is "true", the name server is in stealth mode. This means that its NS record is not published among the zone data, and it does not respond to queries from resolvers and other name servers.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "true" or "false".

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting stealth
my $stealth = $nameserver->stealth();
# Modifying stealth
$nameserver->stealth("true");
```

TSIGalgorithm( )

Use this method to set or retrieve the algorithm of the TSIG key you want to use.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired algorithm of the TSIG key. Valid values are "HMAC-SHA256" and "HMAC-MD5", which is the default.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting TSIGalgorithm
my $TSIGalgorithm = $nameserver->TSIGalgorithm();
# Modifying TSIGalgorithm
$nameserver->TSIGalgorithm("HMAC-SHA256");
```

TSIGkey( )

Use this method to set or retrieve the TSIG key. This key must also be present on the external primary server. You can generate a TSIG key, or you can obtain the TSIG key name and key from the external name server either by accessing the appliance yourself or by requesting the appliance administrator to deliver them to you through some out-of-band mechanism. Then type or copy-and-paste that name and key into the appropriate fields.

OR

Use DNS One 2.x TSIG: If you want to use TSIG authentication and the external primary name server is an Infoblox appliance running DNS One 2.x code. The local appliance generates the required TSIG key for authenticating DNS messages to and from appliances running DNS One 2.x code.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired TSIGkey of the name server in string format. Valid values are ":2xCOMPAT" or a TSIG key string.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting TSIGkey
my $TSIGkey = $nameserver->TSIGkey();
# Modifying TSIGname
$nameserver->TSIGkey("ZX1jVJl7C58GT/sc7Q3uc2==");
```

TSIGname( )

Use this method to set or retrieve the name of the TSIG key you want to use.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired name of the TSIG key in string format.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
# Getting TSIGname
my $TSIGname = $nameserver->TSIGname();
# Modifying TSIGname
$nameserver->TSIGname("tsig2_name");
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object such as add, modify. This sample also includes error handling for the operations.

##Preparation prior to a DNS nameserver object insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Session created successfully\n";
```

#Create a nameserver object

```
 my $nameserver1 = Infoblox::DNS::Nameserver->new(
    name     => "ns1.domain.com",
    ipv4addr => "10.4.5.6",
    stealth  => "false",
    TSIGname => "tsig_name",
    TSIGkey  => "ZX1jVJl7C58GT/sc7Q3ucA==",
 );
 unless ($nameserver1){
     die("Construct Nameserver failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());
  }
```

```
print "Nameserver object created successfully\n";
```

 # Create a zone and use $nameserver1

```
#create a zone and use $nameserver1
my $zone = Infoblox::DNS::Zone->new(
   name    => "domain.com",
   multiple_primaries => [$nameserver1],
 );

#put zone into session
$session->add($zone)
  or die("Zone creation failed: ",
           Infoblox::status_code() . ":" . Infoblox::status_detail());

print " Zone creation successful\n";
```

#Get and modify the name server

```
#get Zone object from session
my @result = $session->get(
    object => "Infoblox::DNS::Zone",
    name   => "domain.com"
);

unless (scalar(@result) == 0) {
    my $zone = $result[0];

    if ($zone) {

        #modify ipv4addr value
        $nameserver1->ipv4addr("5.5.5.5");
        $zone->multiple_primaries([$nameserver1]);

        #update session
        $session->modify($zone)
            or die("modify zone domain.com failed: ",
               $session->status_code(), $session->status_detail());
           }
     } else {
         print "No zone found.";
     }
    ####PROGRAM ENDS####
```

NAME

Infoblox::DNS::Nameserver::Address - NS Name Server object.

DESCRIPTION

The NS Name Server object provides IP address information for the name server associated with an NS record.

CONSTRUCTOR

```
my $rootns = Infoblox::DNS::Nameserver::Address->new(
             address => $address,                  #Required
             auto_create_ptr => "true" | "false"   #Optional / Default "true"
);
```

MODULE METHODS

You can apply the following functions to an NS Name Server object:

Infoblox::DNS::Record::NS->nameservers( )

Use this function to specify the IP addresses associated with the NS record. See Infoblox::DNS::Record::NS->nameservers() for parameters and return values.

Example

```
#Construct an NS Name Server object
my $ns1 = Infoblox::DNS::Nameserver::Address->new(
              address  => "10.0.0.1"
);

# Configure a name server address on the NS record object
$ns_record->nameservers([$ns1]);
```

METHODS

This section describes all the methods you can use to configure and retrieve the attribute values of an NS Name Server object.

address( )

Use this method to set or retrieve the IPv4 address of the name server.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

The IPv4 address (32 bits) of the name server.

Returns

If you specify a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you do not specify a parameter, the method returns the attribute value.

Example

```
#Get the address
my $addr = $ns->address();
#Modify the address
$ns->address("10.0.0.1");
```

auto_create_ptr( )

Use this method to set or retrieve the auto_create_ptr flag of the name server. When this flag is set to true, PTR records are automatically created for NS records created in a reverse zone.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Valid values are "true" or "false".

Returns

If you specify a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you do not specify a parameter, the method returns the attribute value.

Example

```
#Get auto_create_ptr
my $aptr = $ns->auto_create_ptr();
#Modify auto_create_ptr
$rootns->auto_create_ptr("false");
```

NAME

Infoblox::DNS::OrderedResponsePolicyZones - Ordered Response Policy Zones object.

DESCRIPTION

An object type to set or retrieve an ordered list of Response Policy Zones in a DNS view.

Server will reject zones that are disabled or zones without primary name server assigned.

CONSTRUCTOR

```
 my $ordered_rpz = Infoblox::DNS::OrderedResponsePolicyZones->new(
                        view                    => $view,
#Required
                        rp_zones                => [$response_policy_zone1, $response_policy_zone2, ...],
#Required
 );
```

SESSION METHODS

This section describes all the methods in the Infoblox::Session module that you can apply to an Ordered Response Policy Zones object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

No object is added in this method, but the Response Policy Zones for the specified DNS View assume the specified order.

Example

```
       #Construct an object
       my $ordered_rpz = Infoblox::DNS::OrderedResponsePolicyZones->new(
                                                                  view => $view,
                                                                  rp_zones  => [$response_policy_zone1,
      $response_policy_zone2]
                                                                 );
       #Submit for addition
       my $response = $session->add( $ordered_rpz );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
       Apply the following attributes to get a specific Response Policy Zones object:

       view - Required. An Infoblox::DNS::View object.
```

Examples

```
       my @retrieved_objs = $session->get(
```

```
        object   => "Infoblox::DNS::OrderedResponsePolicyZones",
        view  => $view
    );
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

No object is modified in this method, but the Response Policy Zones for the specified DNS View assume the specified order.

Example

```
#Use this method to modify the order of Response Policy Zones.
$ordered_rpz->rp_zones([$rpz4, $rpz2, $rpz3, $rpz1]);
#Submit modification
my $response = $session->modify( $ordered_rpz );
```

METHODS

Use the following methods to access the attributes of an Infoblox::DNS::OrderedResponsePolicyZones object. Specify a parameter to set the attribute's value, or omit the parameter to get the attribute's value.

view( )

Use this method to set or retrieve the DNS View object.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An Infoblox::DNS::View object.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting view
my $view = $ordered_rpz->view();
#Modifying view
$ordered_rpz->view($view1);
```

rp_zones( )

Use this method to set or retrieve an ordered list of Response Policy Zones object references.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An array reference of defined Infoblox::DNS::Zone objects.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Getting zones list reference
my $zone_list_ref = $ordered_rpz->rp_zones();
#Getting zones list
my @zone_list = @{$oz->rp_zones()};
#Get Zone from list
my $zone = $zone_list[0];
#Modifying zones
$ordered_rpz->rp_zones([$rpz1, $rpz2, @rpz3]);
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to the Response Policy Zone reordering

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox appliance
my $host_ip =  "192.168.1.2";
my $session = Infoblox::Session->new(
    master   => $host_ip,
    username => "admin",
    password => "infoblox"
    );
unless($session){
        die("Constructor for session failed: ",
               Infoblox::status_code(). ":" . Infoblox::status_detail());
}
print "Session created successfully.\n";

my $memberns1 = Infoblox::DNS::Member->new(
   name     => $host_name,
   ipv4addr => $node_ip,
);

my $rpz_zone = Infoblox::DNS::Zone->new (
   name     => 'rpz.com',
   comment  => "this is a demo zone 1",
   disable  => "false",
   rpz_policy => "GIVEN",
   primary => $memberns1,
);

$session->add($rpz_zone)
   or die("Add zone failed: ",
              $session->status_code(). ":" .$session->status_detail());

print"Response policy zone added successfully.\n";

$rpz_zone = Infoblox::DNS::Zone->new (
   name     => 'rpz1.com',
   comment  => "this is a demo zone 2",
   disable  => "false",
   rpz_policy => "GIVEN",
   primary => $memberns1,
);

$session->add($rpz_zone)
   or die("Add zone failed: ",
              $session->status_code(). ":" .$session->status_detail());

print"Response policy zone added successfully.\n";

$rpz_zone = Infoblox::DNS::Zone->new (
   name     => 'rpz2.com',
   comment  => "this is a demo zone 3",
   disable  => "false",
   rpz_policy => "GIVEN",
   primary => $memberns1,
);

$session->add($rpz_zone)
   or die("Add zone failed: ",
              $session->status_code(). ":" .$session->status_detail());

print"Response policy zone added successfully.\n";
```

#Get the current Response Policy Zones order.

```
my $orpz = $session->get(
    object  => "Infoblox::DNS::OrderedResponsePolicyZones",
    view => "default",
);

unless($orpz){
      die("Get Response Policy Zones failed: ",
               $session->status_code() . ":" . $session->status_detail());
```

```
      }

print "Get Response Policy Zones object found at least 1 matching entry\n";

my ($z1, $z2, $z3) = @{$orpz->rp_zones()};

print "The current order of the Response Policy Zones is : " . $z1->comment() . "," .
              $z2->comment() . "," . $z3->comment() . "\n";
```

#Modify the Response Policy Zones order.

```
$orpz->rp_zones([$z3, $z2, $z1]);

#Apply the change
$session->modify($orpz)
     or die("Modify Response Policy Zones failed: ",
              $session->status_code(). ":" .$session->status_detail());

print "Response Policy Zones modified successfully.\n";

$orpz = $session->get(
   object  => "Infoblox::DNS::OrderedResponsePolicyZones",
   view => "default",
);

unless($orpz){
     die("Get Response Policy Zones failed: ",
              $session->status_code() . ":" . $session->status_detail());
     }

print "Get Response Policy Zones object found at least 1 matching entry\n";

($z1, $z2, $z3) = @{$orpz->rp_zones()};

print "The current order of the Response Policy Zones is : " . $z1->comment() . "," .
              $z2->comment() . "," . $z3->comment() . "\n";

NAME

Infoblox::DNS::Record::A - DNS A record object.

DESCRIPTION

An A (address) record maps a domain name to an IPv4 address. To define a specific name-to-address mapping, add an A record to a previously defined authoritative forward-mapping zone.

Note that you must specify only one view for the attribute "views".

CONSTRUCTOR

```
 my $bind_a = Infoblox::DNS::Record::A->new (
     ipv4addr              => $ipv4addr,                                                                  #
Required
     name                  => $fqdn,                                                                      #
Required
     comment               => $string,                                                                    #
Optional / Default is empty
     disable               => "true" | "false"                                                            #
Optional / Default "false"
     extattrs              => { $string => $extattr, ... },                                               #
Optional / Default is undefined
     extensible_attributes => { $string => $string | $num, $string => [ $string | $num, ... ], ... },   #
Optional / Default is undefined
     last_discovered       => $string,                                                                    #
Optional / Default is empty
     ttl                   => $num | undef,                                                               #
Optional / Default is undefined
     views                 => [$View1],                                                                   #
Optional / Default is "default" view
     creator               => "DYNAMIC" | "STATIC",                                                       #
Optional / Default is "STATIC"
     ddns_protected        => "true" | "false",                                                           #
Optional / Default is "false"
     ddns_principal        => $string,                                                                    #
Optional / Default is undefined
     forbid_reclamation    => "true" | "false",                                                           #
Optional / Default is "false"
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DNS A object.

Infoblox::Session->add( )

Use this method to add an object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $bind_a = Infoblox::DNS::Record::A->new (
    ipv4addr => "1.1.1.1",
    name     => "bind_a.domain.com",
    comment  => "this is a demo bind_a record",
    disable  => "true",
    ttl      => "33",
    views    => [$view1]  );
# Submit for addition
my $response = $session->add( $bind_a );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
Apply the following attributes to get a specific DNS A object:

  name                  - Optional. A host name in string format.
  view                  - Optional. The DNS view in which the A record is located. By default, all
DNS views are searched. But if you omit this attribute and specify a zone, the appliance searches the
'default' view only.
  zone                  - Optional. A zone name in FQDN format.
  ipv4addr              - Optional. The address of the host record.
  reclaimable           - Optional. The flag that indicates whether the record is reclaimable or not.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  creator               - Optional. Record creator.
  ddns_principal        - Optional. GSS-TSIG principal that owns the record.
```

```
  v_cluster             - Optional. Discovered VMware cluster name.
  v_datacenter          - Optional. Discovered VMware datacenter name.
  v_host                - Optional. Discovered VMware server name.
  v_name                - Optional. Discovered VMware host or virtual machine name.
  v_netadapter          - Optional. Discovered VMware physical network adapter name.
  v_switch              - Optional. Discovered VMware virtual switch name.
  v_type                - Optional. Discovered VMware entity type (possible values: "VirtualMachine",
"HostSystem", "VirtualCenter").
```

Example

```
my @retrieved_objs = $session->get(
    object => "Infoblox::DNS::Record::A",
    name   => "bind_a.domain.com",
    view   => "default" );

#get all DNS A recods with the extensible attribute 'Site'
my @retrieved_objs = $session->get(
   object => "Infoblox::DNS::Record::A",
   extensible_attributes => { 'Site' => 'Santa Clara' });

# get DNS A records by v_type:
my @retrieved_objs = $session->get(
   object    => 'Infoblox::DNS::Record::A',
   v_type    => 'VirtualMachine');
```

Infoblox::Session->modify( )

Use this method to modify an object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use method to modify the comment.
$bind_a->comment("this is a modified comment");
# Submit modification
my $response = $session->modify( $bind_a );
```

Infoblox::Session->remove( )

Use this method to submit to remove an object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific object, and then submit this object for removal.

Key References

```
remove_options - Optional. A hash reference containing the following attributes:

+-------------------------------------------------------------------------------------------+
| remove_associated_ptr - Optional. Boolean flag that indicates whether the associated PTR  |
|                         record should be removed while deleting the specified A record.   |
+-------------------------------------------------------------------------------------------+
```

Example

```
# Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::DNS::Record::A",
    name   => "bind_a.domain.com",
    view   => "default" );
# Find the desired object from the retrieved list.
my $desired_a = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove(
    $desired_a,
    remove_options => {'remove_associated_ptr' => 'true'} );
```

Infoblox::Session->search( )

Use this method to search for DNS A record objects in the Infoblox appliance. See Infoblox::Session->search() for para meters and return values.

Key References

```
Apply the following attributes to search for a DNS A record object:

  name                  - Optional. A host name in string format (regular expression).
  view                  - Optional. The DNS view in which the A record is located. By default, all
DNS views are searched. But if you omit this attribute and specify a zone, the appliance searches the
'default' view only.
  zone                  - Optional. A zone name in FQDN format.
```

```
  comment               - Optional. A comment in string format (regular expression).
  ipv4addr              - Optional. The address of the host record (regular expression).
  reclaimable           - Optional. The flag that indicates whether the record is reclaimable or not.
  extattrs              - Optional. A hash reference containing extensible attributes.
  extensible_attributes - Optional. A hash reference containing extensible attributes.
  creator               - Optional. Record creator.
  ddns_principal        - Optional. GSS-TSIG principal that owns the record.
  v_cluster             - Optional. Discovered VMware cluster name (regular expression).
  v_datacenter          - Optional. Discovered VMware datacenter name (regular expression).
  v_host                - Optional. Discovered VMware server name (regular expression).
  v_name                - Optional. Discovered VMware host or virtual machine name (regular
expression).
  v_netadapter          - Optional. Discovered VMware physical network adapter name (regular
expression).
  v_switch              - Optional. Discovered VMware virtual switch name (regular expression).
  v_type                - Optional. Discovered VMware entity type (possible values: "VirtualMachine",
"HostSystem", "VirtualCenter").
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all DNS A objects that match "domain.com" in the default DNS view
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::Record::A",
    name   => 'domain\.com',
    view   => "default" );

# search for all DNS A records in the "domain.com" zone of the default view
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::Record::A",
    zone   => "domain.com",
    view   => "default" );

#get all DNS A recods with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
  object => "Infoblox::DNS::Record::A",
  extensible_attributes => { 'Site' => 'Santa Clara' });

# search DNS A records by v_datacenter:
my @retrieved_objs = $session->search(
   object       => "Infoblox::DNS::Record::A",
   v_datacenter => "test.*");
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an A record

comment( )

Use this method to set or retrieve the descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $bind_a->comment();
#Modify comment
$bind_a->comment("Modifying the DNS A comment");
```

cloud_info( )

Use this method to retrieve cloud API related information for the Infoblox::DNS::Record::A object.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $object->cloud_info();
```

creator( )

Use this method to set or retrieve the record creator.

Note that changing creator from or to 'SYSTEM' value is not allowed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Paramter

The valid values are 'STATIC' and 'DYNAMIC'. The default value is 'STATIC'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get creator value
my $creator = $object->creator();

#Modify creator value
$object->creator("DYNAMIC");
```

creation_time( )

Use this method to retrieve the creation time for the record. This is a read-only attribute.

Parameter

None

Returns

The valid return value is a number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get creation_time value
my $creation_time = $object->creation_time();
```

ddns_principal( )

Use this method to set or retrive the GSS-TSIG principal that owns this record.

Note that you cannot set ddns_principal for 'STATIC' and 'SYSTEM' records.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Paramter

The GSS-TSIG principal FQDN (Fully Qualified Domain Name) format. The FQDN consists of the hostname followed by the domain name (example: abc.com). A hostname can have a maximum of 256 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_principal value
my $ddns_principal = $object->ddns_principal();

#Modify ddns_principal value
$object->ddns_principal('foo.com');
```

ddns_protected( )

Use this method to set or retrieve the flag that indicates whether DDNS updates for this record are allowed or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to protect record from DDNS updates and 'false' to allow DDNS updates for the specified record.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_protected value
my $ddns_protected = $object->ddns_protected();

#Modify ddns_protected value
$object->ddns_protected('true');
```

disable( )

Use this method to set or retrieve the disable flag of a DNS record.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value for this field is false. The DNS record is enabled.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $bind_a->disable();
#Modify disable
$bind_a->disable("true");
```

discovered_data( )

Use this method to retrieve the discovered data of an A Record object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Data object.

Example

```
#Get discovered_data value
my $discovered_data = $object->discovered_data();
```

discovered_name( )

Use this method to retrieve the discovered name of an A Record object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
my $discovered_name = $bind_a->discovered_name();
```

discoverer( )

Use this method to retrieve the discoverer of an A Record object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $bind_a->discoverer();
```

dns_name( )

Use this method to retrieve the host name in punycode format. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $bind_a->dns_name();
```

first_discovered( )

Use this method to retrieve the date and time that the A Record object was first discovered.

Parameter

none

Returns

The method returns the date and time when the A Record object was first discovered.

Example

```
#Get first_discovered
my $first_discovered = $bind_a->first_discovered();
```

forbid_reclamation( )

Use this method to set or retrieve the flag that indicates whether the reclamation is allowed for the record or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to forbid reclamation for the record and 'false' to allow it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get forbid_reclamation
my $forbid_reclamation = $object->forbid_reclamation();
#Modify forbid_reclamation
```

```
$object->forbid_reclamation('true');
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DNS A record object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $bind_a->extattrs();
#Modify extattrs
$bind_a->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DNS A record.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $bind_a->extensible_attributes();
#Modify extensible attributes
$bind_a->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ] });
```

ipv4addr( )

Use this method to set or retrieve the the IPv4 address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv4 address is a 32-bit number in dotted decimal notation. It consists of four 8-bit groups of decimal digits separated by decimal points (example: 192. 168.1.2).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv4addr
my $ipv4addr = $bind_a->ipv4addr();
#Modify ipv4addr
$bind_a->ipv4addr("2.2.2.2");
```

last_discovered( )

Use this method to retrieve the time this object was last seen by a discovery job.

The default value for this field is empty.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get last_discovered
my $last_discovered = $bind_a->last_discovered();
```

last_queried( )

Use this method to retrieve the time when the associated record was last queried. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_queried
my $last_queried = $bind_a->last_queried();
```

mac_address( )

Use this method to retrieve the discovered MAC address of this object.

The default value for this field is empty.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get mac_address
my $mac_address = $bind_a->mac_address();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $bind_a->ms_ad_user_data();
```

name( )

Use this method to set or retrieve the host name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The attribute value can be in unicode format.

Parameter

Hostname in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the hostname followed by the domain name (example: abc.com). A hostname can have a maximum of 256 bytes.

Infoblox also supports wildcard A records. A wildcard A record maps all the hostnames in a domain to a single IP address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $bind_a->name();
#Modify name
$bind_a->name("bind_a.domain.com");
```

netbios( )

Use this method to retrieve the name in the NetBIOS reply that responded to a NetBIOS query.

Returns

The method returns the attribute value.

Example

```
#Get netbios
my $netbios = $bind_a->netbios();
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $bind_a->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device IP address.

Example

```
#Get network_component_ip
my $network_component_ip = $bind_a->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device name.

Example

```
#Get network_component_name
my $network_component_name = $bind_a->network_component_name();
```

network_component_port_description( )

Use this method to retrieve the description of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device port description.

Example

```
#Get network_component_port_description
my $network_component_port_description = $bind_a->network_component_port_description();
```

network_component_port_name( )

Use this method to retrieve the name of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the name of the port on the network device.

Example

```
#Get network_component_port_name
my $network_component_port_name = $bind_a->network_component_port_name();
```

network_component_port_number( )

Use this method to retrieve the number of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device port number.

Example

```
#Get network_component_port_number
my $network_component_port_number = $bind_a->network_component_port_number();
```

network_component_type( )

Use this method to retrieve the type of the network device that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device type.

Example

```
#Get network_component_type
my $network_component_type = $bind_a->network_component_type();
```

os( )

Use this method to retrieve the operating system associated with this A record.

Returns

The method returns the attribute value.

Example

```
#Get os
my $os = $bind_a->os();
```

port_duplex( )

Use this method to retrieve the duplex setting of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device port duplex setting. Returned values, if any, are one of the following:

```
Full
Half
```

Example

```
#Get port_duplex
my $port_duplex = $bind_a->port_duplex();
```

port_link_status( )

Use this method to retrieve the link status of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the port link status. Returned values, if any, are one of the following:

```
Connected
Not Connected
Unknown
```

Example

```
#Get port_link_status
my $port_link_status = $bind_a->port_link_status();
```

port_speed( )

Use this method to retrieve the speed of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device port speed value. Returned values, if any, are one of the following:

```
10M
100M
1G
10G
100G
Unknown
```

Example

```
#Get port_speed
my $port_speed = $bind_a->port_speed();
```

port_status( )

Use this method to retrieve the status of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device port status. Returned values, if any, are one of the following:

```
Up
Down
Unknown
```

Example

```
#Get port_status
my $port_status = $bind_a->port_status();
```

port_vlan_description( )

Use this method to retrieve the VLAN description of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the VLAN description of the network device port.

Example

```
#Get port_vlan_description
my $port_vlan_description = $bind_a->port_vlan_description();
```

port_vlan_name( )

Use this method to retrieve the VLAN name of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the VLAN name of the network device port.

Example

```
#Get port_vlan_name
my $port_vlan_name = $bind_a->port_vlan_name();
```

port_vlan_number( )

Use this method to retrieve the VLAN number of the network device port that is connected to the A Record object.

Parameter

none

Returns

The method returns the network device port VLAN number.

Example

```
#Get port_vlan_number
my $port_vlan_number = $bind_a->port_vlan_number();
```

reclaimable( )

Use this method to retrieve the flag that indicates whether the record is reclaimable or not.

Parameter

None

Returns

The method returns the attribute value.

Example

```
#Get reclaimable
my $reclaimable = $object->reclaimable();
```

ttl( )

Use this method to set or retrieve the Time to Live (TTL) value.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is undefined which indicates that the record inherits the TTL value of the zone.

Specify a TTL value to override the TTL value at the zone level.

Parameter

A 32-bit integer (range from 0 to 4294967295) that represents the duration in seconds that the record is cached. Zero indicates that the record should not be cached.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ttl
my $ttl = $bind_a->ttl();
#Modify ttl
$bind_a->ttl(1800);
#Un-override ttl
$bind_a->ttl(undef);
```

views( )

Use this method to set or retrieve the view of the A record.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value is the "default" view, which means the A record is located under the default view.

Parameter

Array reference of defined Infoblox::DNS::View objects.

Note that the array size must be 1.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get views
my $ref_views = $bind_a->views();
#Modify views, list of Infoblox::DNS::View objects
$bind_a->views([$view1]);
```

v_cluster( )

Use this method to retrieve the name of the VMware cluster associated with the A Record object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware cluster name. The default value is an empty string.

Example

```
#Get v_cluster
my $v_cluster = $bind_a->v_cluster();
```

v_datacenter( )

Use this method to retrieve the name of the VMware datacenter associated with the A Record object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware datacenter name. The default value is an empty string.

Example

```
#Get v_datacenter
my $v_datacenter = $bind_a->v_datacenter();
```

v_host( )

Use this method to retrieve the name of the VMware host associated with the A Record object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware host name. The default value is an empty string.

Example

```
#Get v_host
my $v_host = $bind_a->v_host();
```

v_name( )

Use this method to retrieve the name of the VMware entity associated with the A Record object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware entity name. The default value is an empty string.

Example

```
#Get v_name
my $v_name = $bind_a->v_name();
```

v_netadapter( )

Use this method to retrieve the name of the physical network adapter through which the VMware entity is connected to the appliance. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the network adapter name. The default value is an empty string.

Example

```
#Get v_netadapter
my $v_netadapter = $bind_a->v_netadapter();
```

v_switch( )

Use this method to retrieve the name of the virtual switch through which the VMware entity is connected to the appliance. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the virtual switch name. The default value is an empty string.

Example

```
#Get v_switch
```

```
my $v_switch = $bind_a->v_switch();
```

v_type( )

Use this method to retrieve the type of VMware entity associated with the A Record object. This method is read-only.

Parameter

none

Returns

This method returns a string that contains the VMware entity type. The default value is an empty string. The returned value, if any, can be one of the following:

```
VirtualMachine
HostSystem
VirtualCenter
```

Example

```
#Get v_type
my $v_type = $bind_a->v_type();
```

zone( )

Use this method to retrieve the zone name of a DNS A record. This method is read-only and cannot be set.

Parameter

None

Returns

Returns the attribute value.

Example

```
# Get zone
my $zone = $bind_a->zone();
```

SAMPLE CODE

The following sample code demonstrates the different functions that can be applied to an object, such as add, search, modify, and remove. This sample also includes error handling for the operations.

#Preparation prior to a DNS A record insertion

```
#PROGRAM STARTS: Include all the modules that will be used
use strict;
use Infoblox;

#Create a session to the Infoblox Appliance
my $session = Infoblox::Session->new(
    master   => "192.168.1.2",
    username => "admin",
    password => "infoblox"
);
unless ($session) {
   die("Construct session failed: ",
       $session->status_code() . ":" . $session->status_detail());
}
print "Session created successfully\n";

#Create the zone prior to an A record insertion
my $zone = Infoblox::DNS::Zone->new(name => "domain.com");
unless ($zone) {
   die("Construct zone failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "Zone object created successfully\n";

#Verify if the zone exists
my $object = $session->get(object => "Infoblox::DNS::Zone", name => "domain.com");
unless ($object) {
   print "Zone does not exist on server, safe to add the zone\n";
   $session->add($zone)
```

```
        or die("Add zone failed: ",
               $session->status_code() . ":" . $session->status_detail());
}
print "Zone added successfully\n";
```

#Create a DNS A record

```
#Construct a DNS A object
my $bind_a = Infoblox::DNS::Record::A->new(
    name     => "bind_a.domain.com",
    comment  => " this is a demo bind_a record ",
    ipv4addr => "1.1.1.1"
);
unless ($bind_a) {
   die("Construct DNS record A failed: ",
       Infoblox::status_code() . ":" . Infoblox::status_detail());
}
print "DNS A object created successfully\n";

#Add the DNS A record object to Infoblox Appliance through a session
$session->add($bind_a)
    or die("Add record A failed: ",
           $session->status_code() . ":" . $session->status_detail());
print "DNS A object added to server successfully\n";
```

#Search for a specific DNS A record

```
#Search all A records that match "domain.com"
my @retrieved_objs = $session->search(
    object => "Infoblox::DNS::Record::A",
    name   => 'domain\.com'
);
my $object = $retrieved_objs[0];
unless ($object) {
    die("Search record A failed: ",
        $session->status_code() . ":" . $session->status_detail());
}
print "Search DNS A object found at least 1 matching entry\n";

#Search all A records that start with "bind" and end with ".domain.com"

NAME

Infoblox::DNS::Record::AAAA - DNS AAAA record object.

DESCRIPTION

An AAAA record, also known as a quad A address record, maps a domain name to an IPv6 address. To define a specific name-to-address mapping, add an AAAA record to a previously defined authoritative forward-mapping zone.

Note that you must specify only one view for the attribute "views".

CONSTRUCTOR

```
 my $bindaaaa = Infoblox::DNS::Record::AAAA->new (
     ipv6addr              => $ipv6addr,                                                  #
Required
     name                  => $fqdn,                                                      #
Required
     comment               => $string,                                                    #
Optional / Default is empty
     extattrs              => { $string => $extattr, ... },                               #
Optional / Default is undefined
     extensible_attributes => { $string => $string | $num, $string => [ $string | $num, ... ], ... }, #
Optional / Default is undefined
     disable               => "true" | "false"                                            #
Optional / Default "false"
     ttl                   => $num | undef,                                               #
Optional / Default is undefined
     views                 => [$View1],                                                   #
Optional / Default is "default" view
     creator               => "DYNAMIC" | "STATIC",                                       #
Optional / Default is "STATIC"
     ddns_protected        => "true" | "false",                                           #
Optional / Default is "false"
     ddns_principal        => $string,                                                    #
Optional / Default is undefined
     forbid_reclamation    => "true" | "false",                                           #
Optional / Default is "false"
 );
```

You cannot set both extattrs and extensible_attributes attributes at the same time.

SESSION METHODS

This section describes all the methods in Infoblox::Session module that you can apply to a DNS AAAA record object.

Infoblox::Session->add( )

Use this method to add a AAAA record object to the Infoblox appliance. See Infoblox::Session->add() for parameters and return values.

Example

```
#Construct an object
my $bindaaaa = Infoblox::DNS::Record::AAAA->new(
    name     => "aaaa1.domain.com",
    comment  => "add a DNS AAAA aaaa1.domain.com",
    ipv6addr => "aaaa:1111:bbbb:2222:cccc:3333:dddd:4444",
    disable  => "true",
    ttl      => "33",
    views    => [$view1]  );
# Submit for addition
my $response = $session->add( $bindaaaa );
```

Infoblox::Session->get( )

Use this method to retrieve all the matching objects from the Infoblox appliance. See Infoblox::Session->get() for parameters and return values.

Key References

```
 Apply the following attributes to get a specific DNS AAAA object:

 name                              - Optional. A host name in string format.
 view                              - Optional. The DNS view in which the host record is located. By
default, all DNS views are searched. But if you omit this attribute and specify a zone, the appliance
searches the 'default' view only.
 zone                              - Optional. A zone name in FQDN format.
 ipv6addr                          - Optional. The address of the AAAA record.
 creator                           - Optional. Record creator.
 ddns_principal                    - Optional. GSS-TSIG principal that owns the record.
 reclaimable                       - Optional. The flag that indicates whether the record is
reclaimable or not.
 extattrs                          - Optional. A hash reference containing extensible attributes.
 extensible_attributes             - Optional. A hash reference containing extensible attributes.

 discovered_duid                   - Optional. Discovered DHCPv6 UID.
 discovered_name                   - Optional. Discovered name.
 discoverer                        - Optional. Discoverer name.
 first_discovered                  - Optional. Time of the first discovery.
 last_discovered                   - Optional. Time of the last discovery.
 netbios                           - Optional. Discovered NetBIOS name.
 network_component_description     - Optional. Discovered network component description.
 network_component_ip              - Optional. Discovered network component IP address.
 network_component_name            - Optional. Discovered network component name.
 network_component_port_description - Optional. Discovered network component port description.
```

```
network_component_port_name        - Optional. Discovered network component port name.
network_component_port_number      - Optional. Discovered network component port number.
network_component_type             - Optional. Discovered network component type.
os                                 - Optional. Discovered OS.
port_duplex                        - Optional. Discovered port duplex settings.
port_link_status                   - Optional. Discovered port link status.
port_speed                         - Optional. Discovered port speed settings.
port_status                        - Optional. Discovered port status settings.
port_vlan_description              - Optional. Discovered port VLAN description.
port_vlan_name                     - Optional. Discovered port VLAN name.
port_vlan_number                   - Optional. Discovered port VLAN number.
```

Example

```
my @retrieved_objs = $session->get(
                      object => "Infoblox::DNS::Record::AAAA",
                      name   => "aaaa1.domain.com",
                      view   => "default" );

# get all the DNS AAAA records in the "domain.com" zone of the default view
my @retrieved_objs = $session->get(
                      object => "Infoblox::DNS::Record::AAAA",
                      zone   => "domain.com",
                      view   => "default" );

#get all DNS AAAA recods with the extensible attribute 'Site'
my @retrieved_objs = $session->get(
   object => "Infoblox::DNS::Record::AAAA",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

Infoblox::Session->modify( )

Use this method to modify a AAAA record object in the Infoblox appliance. See Infoblox::Session->modify() for parameters and return values.

Example

```
# Use method to modify the comment.
$bindaaaa->comment("this is a modified comment");
# Submit modification
my $response = $session->modify( $bindaaaa );
```

Infoblox::Session->remove( )

Use this method to remove a AAAA record object from the Infoblox appliance. See Infoblox::Session->remove() for parameters and return values.

To remove a specifc object, first use `get()` or `search()` to retrieve the specific AAAA record object, and then submit this object for removal.

Key References

```
remove_options - Optional. A hash reference containing the following attributes:

+-------------------------------------------------------------------------------------------+
| remove_associated_ptr - Optional. Boolean flag that indicates whether the associated PTR  |
|                         record should be removed while deleting the specified AAAA record.|
+-------------------------------------------------------------------------------------------+
```

Example

```
# Get the objects with the same name
my @retrieved_objs = $session->get(
    object => "Infoblox::DNS::Record::AAAA",
    name   => "aaaa1.domain.com",
    view   => "default" );
# Find the desired object from the retrieved list.
my $desired_aaaa = $retrieved_objs[0];
# Submit for removal
my $response = $session->remove(
    $desired_aaaa,
    remove_options => {'remove_associated_ptr' => 'true'} );
```

Infoblox::Session->search( )

Use this method to search for DNS AAAA record objects in the Infoblox appliance. See Infoblox::Session->search() for parameters and return values.

Key References

```
 Apply the following attributes, to search for a DNS AAAA record object:

  name                                  - Optional. A host name in string format (regular
expression).
  view                                  - Optional. The DNS view in which the AAAA record is located.
By default, all DNS views are searched. But if you omit this attribute and specify a zone, the
appliance searches the 'default' view only.
  zone                                  - Optional. A zone name in FQDN format.
  comment                               - Optional. Comment in string format (regular expression).
  creator                               - Optional. Record creator.
  ddns_principal                        - Optional. GSS-TSIG principal that owns the record.
  reclaimable                           - Optional. The flag that indicates whether the record is
reclaimable or not.
  ipv6addr                              - Optional. The address of the AAAA record (regular
expression).

  discovered_duid                       - Optional. Discovered DHCPv6 UID (exact search only).
  discovered_name                       - Optional. Discovered name(regex).
  discoverer                            - Optional. Discoverer name(regex).
  first_discovered                      - Optional. Time of the first discovery (in ISO format, exact
search only).
  last_discovered                       - Optional. Time of the last discovery (in ISO format, exact
search only).
  netbios                               - Optional. Discovered NetBIOS name(regex).
  network_component_description         - Optional. Discovered network component description(regex).
  network_component_ip                  - Optional. Discovered network component IP address(regex).
  network_component_name                - Optional. Discovered network component name(regex).
  network_component_port_description    - Optional. Discovered network component port
description(regex).
  network_component_port_name           - Optional. Discovered network component port name(regex).
  network_component_port_number         - Optional. Discovered network component port number (exact
search only).
  network_component_type                - Optional. Discovered network component type(regex).
  os                                    - Optional. Discovered OS (regex).
  port_duplex                           - Optional. Discovered port duplex settings (exact search
only).
  port_link_status                      - Optional. Discovered port link status (exact search only).
  port_speed                            - Optional. Discovered port speed settings (exact search
only).
  port_status                           - Optional. Discovered port status settings (exact search
only).
  port_vlan_description                 - Optional. Discovered port VLAN description(regex).
  port_vlan_name                        - Optional. Discovered port VLAN name(regex).
  port_vlan_number                      - Optional. Discovered port VLAN number(exact search only).

  extattrs                              - Optional. A hash reference containing extensible
attributes.
  extensible_attributes                 - Optional. A hash reference containing extensible
attributes.
```

For more information about searching extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Searching Extensible Attributes.

Example

```
# search for all DNS AAAA objects that match "domain.com" in the default DNS view
my @retrieved_objs = $session->search(
    object  => "Infoblox::DNS::Record::AAAA",
    name    => 'domain\.com',
    view    => "default",
    comment => ".*modified comment" );

# search for all DNS AAAA records in zone "domain.com" of default view
my @retrieved_objs = $session->search(
                     object => "Infoblox::DNS::Record::AAAA",
                     zone   => "domain.com",
                     view   => "default" );

# search all DNS AAAA recods with the extensible attribute 'Site'
my @retrieved_objs = $session->search(
   object => "Infoblox::DNS::Record::AAAA",
   extensible_attributes => { 'Site' => 'Santa Clara' });
```

METHODS

This section describes all the methods that you can use to configure and retrieve the attribute values of an AAAA record

comment( )

Use this method to set or retrieve the descriptive comment.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Desired comment in string format with a maximum of 256 bytes.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get comment
my $comment = $bindaaaa->comment();
#Modify comment
$bindaaaa->comment("Modifying the DNS AAAA comment");
```

cloud_info( )

Use this method to retrieve cloud API related information for the Infoblox::DNS::Record::AAAA object.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get cloud_info
my $cloud_info = $object->cloud_info();
```

creator( )

Use this method to set or retrieve the record creator.

Note that changing creator from or to 'SYSTEM' value is not allowed.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Paramter

The valid values are 'STATIC' and 'DYNAMIC'. The default value is 'STATIC'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get creator value
my $creator = $object->creator();

#Modify creator value
$object->creator("DYNAMIC");
```

creation_time( )

Use this method to retrieve the creation time for the record. This is a read-only attribute.

Parameter

None

Returns

The valid return value is a number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get creation_time value
my $creation_time = $object->creation_time();
```

ddns_principal( )

Use this method to set or retrive the GSS-TSIG principal that owns this record.

Note that you cannot set ddns_principal for 'STATIC' and 'SYSTEM' records.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Paramter

The GSS-TSIG principal FQDN (Fully Qualified Domain Name) format. The FQDN consists of the hostname followed by the domain name (example: abc.com). A hostname can have a maximum of 256 characters.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_principal value
my $ddns_principal = $object->ddns_principal();

#Modify ddns_principal value
$object->ddns_principal('foo.com');
```

ddns_protected( )

Use this method to set or retrieve the flag that indicates whether DDNS updates for this record are allowed or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to protect record from DDNS updates and 'false' to allow DDNS updates for the specified record.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ddns_protected value
my $ddns_protected = $object->ddns_protected();

#Modify ddns_protected value
$object->ddns_protected('true');
```

disable( )

Use this method to set or retrieve the disable flag of a DNS record.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The default value for this field is false. The DNS record is enabled.

Parameter

Specify "true" to set the disable flag or "false" to deactivate/unset it.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get disable
my $disable = $bindaaaa->disable();
#Modify disable
$bindaaaa->disable("true");
```

discovered_data( )

Use this method to retrieve the discovered data of an AAAA Record object. This is a read-only attribute.

Omit the parameter to retrieve the attribute value.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::Discovery::Data object.

Example

```
#Get discovered_data value
my $discovered_data = $object->discovered_data();
```

discovered_duid( )

Use this method to retrieve the discovered DHCPv6 UID (DUID) of an AAAA record object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_duid
my $discovered_duid = $bind_aaaa->discovered_duid();
```

discovered_name( )

Use this method to retrieve the discovered name of an AAAA Record object.

Parameter

none

Returns

The method returns the discovered name.

Example

```
#Get discovered_name
my $discovered_name = $bindaaa->discovered_name();
```

discoverer( )

Use this method to retrieve the discoverer of an AAAA Record object.

Parameter

none

Returns

The method returns the discoverer value.

Example

```
#Get discoverer
my $discoverer = $bindaaa->discoverer();
```

dns_name( )

Use this method to retrieve the host name in punycode format. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value.

Example

```
# Get attribute value
my $value = $bindaaaa->dns_name();
```

extattrs( )

Use this method to set or retrieve the extensible attributes associated with a DNS AAAA record object.

Parameter

Valid value is a hash reference containing the names of extensible attributes and their associated values (Infoblox::Grid::Extattr objects).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extattrs
my $ref_extattrs = $bindaaaa->extattrs();
#Modify extattrs
$bindaaaa->extattrs({ 'Site' => $extattr1, 'Administrator' => $extattr2 });
```

extensible_attributes( )

Use this method to set or retrieve the extensible attributes associated with a DNS AAAA record.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

For valid values for extensible attributes, see Infoblox::Grid::ExtensibleAttributeDef/Extensible Attribute Values.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get extensible attributes
my $ref_extensible_attributes = $bindaaaa->extensible_attributes();
#Modify extensible attributes
$bindaaaa->extensible_attributes({ 'Site' => 'Santa Clara', 'Administrator' => [ 'Peter', 'Tom' ]
});
```

first_discovered( )

Use this method to retrieve the date and time that the AAAA Record object was first discovered.

Parameter

none

Returns

The method returns the date and time when the AAAA Record object was first discovered.

Example

```
#Get first_discovered
my $first_discovered = $bindaaa->first_discovered();
```

forbid_reclamation( )

Use this method to set or retrieve the flag that indicates whether the reclamation is allowed for the record or not.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

Specify 'true' to forbid reclamation for the record and 'false' to allow it. The default value is 'false'.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get forbid_reclamation
my $forbid_reclamation = $object->forbid_reclamation();
#Modify forbid_reclamation
$object->forbid_reclamation('true');
```

ipv6addr( )

Use this method to set or retrieve the the IPv6 address.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

Parameter

An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 12ab:0000:0000:0123:4567:89ab:0000:cdef).

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get ipv6addr
my ipv6addr = $bindaaaa->ipv6addr();
#Modify ipv6addr
$bindaaaa->ipv6addr("aaaa:1111:bbbb:2222:cccc:3333:dddd:5555");
```

last_discovered( )

Use this method to retrieve the time this object was last seen by a discovery job.

This field is blank by default.

Parameter

N/A

Returns

The method returns the attribute value.

Example

```
#Get last_discovered
my $last_discovered = $bindaaa->last_discovered();
```

last_queried( )

Use this method to retrieve the time when the associated record was last queried. This is a read-only attribute.

Parameter

None

Returns

The method returns the attribute value. The number of seconds that have elapsed since January 1st, 1970 UTC.

Example

```
#Get last_queried
my $last_queried = $bindaaaa->last_queried();
```

ms_ad_user_data( )

Use this method to retrieve Microsoft Active Directory users related information. This is a read-only attribute.

Parameter

None

Returns

The valid return value is an Infoblox::Grid::MSServer::AdUser::Data object.

Example

```
#Get ms_ad_user_data
my $ms_ad_user_data = $bindaaaa->ms_ad_user_data();
```

name( )

Use this method to set or retrieve the host name.

Include the specified parameter to set the attribute value. Omit the parameter to retrieve the attribute value.

The attribute value can be in unicode format.

Parameter

Hostname in FQDN (Fully Qualified Domain Name) format. The FQDN consists of the hostname followed by the domain name (example: abc.com). A hostname can have a maximum of 256 bytes.

Infoblox also supports wildcard AAAA records. A wildcard AAAA record maps all the hostnames in a domain to a single IP address.

Returns

If you specified a parameter, the method returns true when the modification succeeds, and returns false when the operation fails.

If you did not specify a parameter, the method returns the attribute value.

Example

```
#Get name
my $name = $bindaaaa->name();
#Modify name
$bindaaaa-> name("aaaa2.domain.com");
```

netbios( )

Use this method to retrieve the name in the NetBIOS reply that responded to a NetBIOS query.

Returns

The method returns the attribute value.

Example

```
#Get NetBIOS
my $netbios = $bindaaa->netbios();
```

network_component_description( )

Use this method to retrieve the description of the network device that is connected to the AAAA Record object.

Parameter

none

Returns

The method returns the network device description.

Example

```
#Get network_component_description
my $network_component_description = $bindaaa->network_component_description();
```

network_component_ip( )

Use this method to retrieve the IP address of the network device that is connected to the AAAA Record object.

Parameter

none

Returns

The method returns the network device IP address.

Example

```
#Get network_component_ip
```

```
my $network_component_ip = $bindaaa->network_component_ip();
```

network_component_name( )

Use this method to retrieve the name of the network device that is connected to the AAAA Record object.

Parameter

none

Returns

The method returns the network device name.

Example

```
